Pennsylvania petroleum, all in cents per pound, are clearly illustrated in the accompanying chart. As you all know, Pennsylvania petroleum is the most expensive crude petroleum in the country. One doesn't have to study the figures very long to see that the quantity of cottonseed oil produced is infinitely small as compared with the amount of petroleum oil, that it is not so good a fuel as petroleum oil, and, lastly, that it costs altogether too much money. In making up this chart, no effort has been made to show the price range of soap stocks and candle pitches, as these products, taken together, do not amount to 10 per cent of the cotton oil crop. Cotton oil pitch, as a byproduct of distillation, was at one time such a drug on the market that a large company almost made up its mind to burn it under its stills, but about that time the war started up, and it was found much better to sell it and buy fuel oil, which was then selling around 75c. per bbl. of 42 gal. This material is used mostly in making roofing and paints.

It is evident from the facts already presented that there is little chance commercially of using vegetable oils for fuel so long as there is a hungry world calling for food in the form of fat.

The best equipment to use in the combustion of cottonseed, peanut, soya bean, and cocoanut and other vegetable oils is somewhat cylindrical in shape and supported on two legs. A full description can be obtained from any book on human anatomy, and the process of operation will be found in various works on physiology, or in Lusk's classic work on the Science of Nutrition.

To show how economical this apparatus is, I have made a few calculations. If you will excuse me for mentioning such a thing as a Ford, which is generally considered a very economical car, making about eighteen miles on a gallon of gasoline, we will compare its performance with the apparatus I have just mentioned. A Ford with a man in it weighs about 1,550 lb. An average man weighs about 155 lb. To move a Ford one mile there is required $\frac{1}{3}$ lb. of gasoline, which is equivalent to 6,333 B.t.u., or 1,580 calories. A man, in walking one mile, uses up fifty-eight calories. Now, a Ford with a man in it weighs ten times as much as a man; therefore, to do the same amount of work in a Ford requires 158 calories, as against fifty-eight calories for the man. If we use cottonseed oil at the present price of 25c. a lb., it will cost 0.36c. for fifty-eight calories used in this form when fed to a man. One hundred and fifty-eight calories of gasoline fed to the Ford is equivalent to about $\frac{1}{30}$ lb. of gasoline, which, at 30c. a gal., would cost $\frac{1}{4}$c. So we see that petroleum fuel, when burned in a Ford, will do twice as much work for the same amount of money as vegetable oil when burned in a man. Chemists, during the last ten or fifteen years, have done wonderful things with vegetable oils by means of hydrogenation. Let us hope that the future may see synthetic edible fats made from petroleum oil, to help cut down the high cost of living.

Alcohol as a Motor Fuel

B. R. Tunison gave an excellent review of the motor fuel situation as a whole and then spoke on alcohol as follows:

That alcohol has real value as a motor fuel no one can deny. This has been demonstrated repeatedly in this country and abroad. That it has not been a factor in this country up to the present time has been due to an economic condition rather than to inherent difficulties in its use. Petroleum products have been so plentiful and cheap that alcohol could not compete with them. But the time is not very far distant when alcohol must become a factor as a motor fuel. That alcohol cannot meet the situation immediately is readily seen from a consideration of our present alcohol production. If all the alcohol produced last year for industrial

purposes were used for fuel, it would make available for motor purposes less than 100,000,000 gal., which represents about 2.5 per cent of our fuel requirements for 1920. However, the so-called blended alcohol fuels are of importance to us at the present time. That these fuels can compete with gasoline even now is being demonstrated by the United States Post Office Department in its airplane mail service. Its tests show a great increase in the number of miles per gal., an increase in power and a very marked saving in the quantity of lubricating oil used.

The following is an analysis of the consumption of alcohol fuel at the various speeds, the tests covering thirty-one non-stop flights between New York and Washington:

R.p.m.	Gal. per Hr.
1440 1460	15 9
1475–1480	20.1
1500	21 5
1520 1525	22.44

A comparative analysis of the fuel consumption with gasoline and alcohol fuel at different engine speeds follows:

R.p.m	1440 1460	1,475	1,500
Gasoline		24	24 17
Alcohol fuel	15 9	20 1	21.5

The following is a comparative analysis of lubricating oil consumption at different engine speeds:

R p.m	1440–1460	1,475	1,500
Gasoline		4.65	4.95
Alcohol fuel	4.5	4.2	4.2

These tests also show much less carbon formation than when using gasoline and the number of forced landings due to fouled spark plugs has been reduced to a minimum.

The U. S. Bureau of Standards has been making exhaustive tests on blended alcohol fuels, and the results of these tests are indeed indicative of the superiority of these alcohol fuels over those ordinarily obtainable. The results of these tests are available at the Bureau of Standards.

It is to be hoped that the United States Government may recognize the significance of this question and endeavor to stimulate a great increase in the production of alcohol and make possible its sale at a lower price by removing to a large extent the costly regulation of its manufacture and distribution. Alcohol should be manufactured in very large quantities and suitably denatured. Alcohol when used in blended fuels such as in admixture with petroleum distillates, benzol, etc., would naturally make a rather unsatisfactory beverage and the interests of the Government would be protected.

It is the writer's belief that this country should make a definite effort to make possible the manufacture, sale and distribution of cheap alcohol by increasing the growth of the industry so that we may benefit by the low unit cost of quantity production, by making the Internal Revenue Bureau supervisions of such a nature that the product may be handled as a cheap commodity, which it really is, instead of a $5 a gal. product as it is now being handled. The Internal Revenue Bureau is at present co-operating to a greater extent than ever before and we hope that these improvements may be made. These steps should be taken, however, before the situation becomes acute and we are forced to solve our fuel problem in the way Germany did.

It is believed that if cheap alcohol is not available the prices of the other suitable fuels will gradually rise until such times as alcohol can compete with them. Undreamed of quantities of alcohol must be produced in the future in order to protect our industries and meet the increasing demand for fuel.

Oils From Shale

Prof. Charles Baskerville closed the program with a splendid review of the possibilities of oil production from shale. He pointed out that very large-scale production would be necessary for financial success, but that a great amount of preliminary development work is now required on a small plant scale to properly test out proposed ideas of retort design and processes. He stated that shale was not a proposition for stock selling promotion schemes, will not yield quick financial returns, but if properly developed, on a conservative basis, it cannot be thought of as a gamble.

Investigation of Sulphur and Phosphorus in Steel

IT WILL be recalled that the American Society for Testing Materials, at its 1918 meeting, recognized that it would be impossible to supply the war needs of steel and yet maintain the specified sulphur and phosphorus limits because high-sulphur coal and high-phosphorus pig and scrap would necessarily have to be consumed. Consequently the limit for sulphur was horizontally raised 0.01 per cent for the period of the emergency in forty-three of its specifications, with an increase in phosphorus of a like amount for acid steels.

About a year ago the limits were again reduced in twenty-nine of these specifications, covering what might be called the special steels, such as spring steels, forging steels, and tire and wheel steels, but action on the remaining, covering tonnage materials such as rails, structural steel and plates, was deferred until 1920. It appeared essential to many parties concerned, however, systematically to procure actual data as to the effect of these elements, in addition to what was already known and published, so recommendations could be based on reliable information. Accordingly a representative committee has been appointed at the initiative of the American Society for Testing Materials, the United States Railroad Administration and the Bureau of Standards for the investigation of this important problem. Associated in the enterprise are also the Society of Automotive Engineers, Association of American Steel Manufacturers, Steel Founders Society of America, United States War and Navy Departments and Shipping Board and the National Research Council. G. K. Burgess of the Bureau of Standards is chairman and C. L. Warwick, secretary of the A.S.T.M., is secretary of the joint committee.

Organization was effected about three months ago, as noted in CHEMICAL & METALLURGICAL ENGINEERING, Nov. 5, 1919, p. 566. During this time three sub-committees have been named and have started to work. The sub-committee on statistics is headed by H. L. Whittemore, of the Bureau of Standards, and is engaged in visiting large manufacturers and users of steel, obtaining information about material high in sulphur and phosphorus which has either proved satisfactory or failed in service, and collecting samples of such material worthy of study. An investigation of the published literature is also under way.

A second sub-committee on manufacture, headed by G. K. Burgess, of the Bureau of Standards, has sub-

mitted a program of tests, and will supervise the manufacture of all metal made for this investigation. Two classes of steels will be studied—one containing moderate amounts of residual impurities, while the other will contain excessive amounts of sulphur or phosphorus added to the metal during a late stage of the manufacture. Below are the analyses to be studied in Series A.

SERIES A. RESIDUAL IMPURITIES

Group	Material	Carbon	Manganese	Phosphorus	Sulphur
1	Rivets, tubes...	0.06 to 0.12	0.35 to 0.40	0.02 to 0.03 0.04 to 0.05 0.06 to 0.07	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08
2	Plates and shapes.....	0.16 to 0.22	0.35 to 0.40	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08
3	Forgings.....	0.45 to 0.55	0.50 to 0.60	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08
4	Rails, wheels, tires.....	0.65 to 0.75	0.60 to 0.70	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08
5	Springs.....	0.95 to 1.05	0.35 to 0.45	0.02 to 0.03 0.04 to 0.05 0.06 to 0.07	0.03 to 0.04 0.05 to 0.06 0.07 to 0.08
6	Castings.....	Compositions not yet determined.			

It will be understood that when studying the effect of sulphur, the phosphorus is to be held as nearly constant as possible and equal to the usual value for that group of materials, and vice versa. Particular emphasis is placed on the requirement that sulphur (or phosphorus) in Series A shall be "residual," that is, sulphur present in the steels by virtue of its being contained in the pig, scrap, ore or fuel used. The opinion is held by many that high sulphur, for instance, is not harmful as such, but is indicative of other undesirable conditions in the steel, inherent in the various stages of manufacture, and that these undesirable conditions do not necessarily accompany high sulphur when the latter is obtained by addition in the ladle or mold. Thus, Unger* made a series of high-sulphur steels from three normal open-hearth heats by adding sulphide during ingot pouring, yet metal containing as high as 0.23 per cent sulphur did not exhibit any expected trouble in rolling due to hot-shortness, while the static properties suffered but slightly. Another similar series of tests on phosphorus was reported by him to the American Iron and Steel Institute in 1918. Both acid and basic open-hearth metal containing up to 0.115 per cent phosphorus gave practically the same tension tests as low-phosphorus material tested transversely to the direction of rolling, while vibratory and impact tests did not fall off as might be expected. In steels of Series B it is realized that very high sulphur probably could not be obtained without additions of extraneous sulphur-bearing material, but these will be added before reaching the mold in order not to duplicate Unger's work.

It has been decided to concentrate upon the sulphur problem first, since it presents the most urgent economic problem. The committee on manufacture has therefore supervised the manufacture of a considerable quantity of rivet steel, and will select such material as is approximately uniform in carbon, manganese and phosphorus, with sulphur varying from 0.03 to 0.08 per cent. About a ton of material of each analysis will be obtained, of which one-half will be used in testing, and the other reserved for future use.

A beginning has also been made in Series B by arranging with a large steel company for the manufacture of three heats of steel, covering groups 2, 3 and 4, from each of which eight ingots will be poured to obtain sulphur content from 0.04 up to 0.15 per cent by the addition of sulphur or pyrite in the pouring box. The upper limits are never likely to be approached in ordinary practice, but should be prosecuted to a point where the material will unquestionably fail from the effect of high impurities.

The committee on tests, headed by F. C. Langenberg, of the Watertown Arsenal, will supervise the mechanical testing. In addition to the usual standard tests of the A.S.T.M. special proof- and service-tests will be made, including, where possible, those for impact and endurance. An endeavor will also be made to determine the amount and types of gases present. The metals under investigation will be also put through fabrication processes and observed under normal service, which should give information essential to the proper interpretation of laboratory work. Under fabrication tests for the soft steel, first to be experimented upon are included such operations as flanging, punching, drifting, cold pressing and riveting. Service tests will also comprise a detailed study of such metal of abnormal analysis whose history can be definitely determined, and which has been discarded through failure or wear.

Much interest has been manifested in this investigation, which is probably unique in being the first concerted effort on the part of interested organizations to make a thorough study of a research problem of considerable magnitude. Manufacturers in particular are volunteering to furnish at their own expense the materials desired. Testing will be done by governmental laboratories, and those of large consumers, such as railroads, so there is no reason to believe that a special fund will have to be raised to defray the expenses.

Iron Age, vol. 97, p. 146.

Aluminum as an Engineering Material

At a joint meeting of the New York Section of the American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers and the Society of Automotive Engineers, held Feb. 10, 1920, the subject of aluminum as an engineering material was presented by a number of speakers.

The subject was not treated as a symposium on aluminum, but by independent outlines, mainly on the characteristics of the aluminum metal, its alloys and their applications, and on aluminum die castings. Graphs and micrographs were presented to show the characteristics of the different alloys, especially Al-Cu, Al-Zn, Al-Fe.

It was developed in the meeting that in the United States practically all the light alloys are aluminum-copper, whereas in Great Britain and other European countries the alloys Al-Zn predominate. This is due in part to the scant information available in America on the Al-Zn alloys. The New Jersey Zinc Co. is now doing quite extensive research work on the properties of Al-Zn alloys, and it might be expected that the results will determine whether the use of aluminum-zinc alloys will be pushed in American markets.

Aluminum die casting offers a series of difficulties, but judging from the increased number and varieties of castings produced recently it can be seen that many troubles have been overcome; it is possible now to make about 150,000 castings with a single die.

Production of aluminum is increasing rapidly and enthusiasts are prophesying that by 1930 aluminum production will equal, if not surpass, that of copper.

Theoretical Study of Nitrogen Fixation by the Electric Arc—I

Chemical Dynamics of the Nitrogen-Oxygen Reactions at the Temperatures of the Arc and During Cooling—Equations of Reaction Velocity and Temperature Equilibrium—Tables of Thermal Nitrification Constants, Reaction Periods and Velocities in Air

By CHARLES P. STEINMETZ

THE national importance of the nitrogen fixation problem consists in the rapidly increasing demand for nitrogen fertilizers to maintain our agricultural productiveness, as the result of the enormous and increasing losses of nitrogen compounds by wastage and dissociation, which is not sufficiently compensated for by the action of the nitrifying bacteria, and the enormous amount of nitric acid required for our national defense in war emergencies, in the manufacture of high explosives.

The arc process of nitrification directly produces nitric acid, while all other processes, chemical and by-product, produce ammonia, and in a sudden emergency the former could therefore be immediately deflected to war purposes, while with the latter processes a new industry will have to be created under the war emergency, the oxidation of the ammonia produced by the fertilizer industry of peace to the nitric acid required by the manufacture of high explosives.

The arc process requires practically nothing but air, water, and electric power as raw materials; but thus far its power consumption is much higher than that of the other processes, and its industrial economy therefore still questionable. On the other hand, apparently so very little broad and general study of the arc process and its underlying phenomena, such as the characteristics of the electric arc, has been done, and there are still so many possibilities in this field that an extensive theoretical and experimental study of the problem of electric arc nitrification appears desirable.

Commercial Developments

The first industrial work[1] was done by Bradley and Lovejoy on nitrogen fixation by the electric arc. After a thorough study of the conditions of nitrification by the electric arc, a plant for the production of nitric acid from the air was established at Niagara Falls. In this plant a very large number of low-current high-voltage transient arcs was used; the efficiency was good, but the cost of installation was high. Probably for this reason, and also due to the low price of Chilean nitrate at that time, the plant was not a commercial success, and had to be abandoned.

The method using a single high-power alternating current arc was developed by Birkland-Eyde. The installation made in Norway was commercially successful, has been greatly enlarged since, and a number of other arc nitrification plants have been built, using the Birkland-Eyde process or modifications thereof. Little further study seems to have been done on the arc nitrification problem in its broadest aspect, but the work chiefly consisted in developing different forms of arc furnaces, such as the Schoenherr furnace, etc., all of which, however, comprise the same principle as the Birkland-Eyde furnace, that is, a high-power, high-voltage alternating current arc moving rapidly with regard to the air acted upon by the arc. The differences between the various arc nitrifying furnaces consist chiefly in the means of producing the relative motion between arc and air: by a magnetic field, by a spiral air blast, by the heat of the arc, by a three-phase arrangement, etc.

Various other solutions of the nitrification problem have since been found and by-product coke, cyanamide and Haber processes have come into extensive industrial use, while others appear promising.

The nitrogen fixed by prehistoric plant life is recovered in the form of ammonia as by-product from coke ovens and gas works. This is now the foremost source of the ammonia supply. It is capable of enormous extension, but, due to the nature of a by-product, is not entirely unlimited.

The cyanamide process is based on the reactions:

$$CaO + 3C = CaC_2 + 3CO$$

$$CaC_2 + N_2 = CaN_2C + C$$

$$CaN_2C + 3H_2O = CaO + CO_2 + 2NH_3$$

The process is partly electrical, as the first step, the formation of calcium carbide, is carried out in the electric furnace. The electric power required for this part of the process is, however, relatively small, only about one-third to one-quarter that required by the Birkland-Eyde process of arc nitrification. It is extensively used industrially.

The Haber process of synthetic ammonia is based on the reaction:

$$N_2 + 3H_2 = 2NH_3$$

As the reaction occurs under condensation, high pressure and low temperature are favorable, but as the reaction velocity decreases with decrease of temperature, a moderate, compromise temperature, the use of a catalyzer and the highest mechanically permissible pressures are employed. This process is reported to be industrially and commercially successful in Germany.

Various other fixation precesses, as cyanide, nitride, etc., have been more or less developed.

It is interesting to note that in all fixation or recovery processes, except the arc process, ammonia is the resulting product, and to convert this into nitric acid the additional process of oxidation is required

$$4NH_3 + 5O_2 = 4NO + 6H_2O$$

and the further conversion of the NO into NO_3H in the same manner as in the arc process.

The oxidation of ammonia occurs under the influence of a catalyst, but unless the ammonia is very pure, as

[1] "Nitrogen Fixation Furnaces," Chem. & Met. Eng., vol. 19, pp. 710-715 and 757-761.

that of the Haber process, electric heating of the catalyzer seems to be necessary to retard its poisoning by the impurities of the ammonia.

Nitrogen Fixation by the Arc

The method of nitrogen fixation by the electric arc differs from all other methods in that it requires as raw materials nothing but electric power and air and water (and some alkaline material, as soda ash, limestone, dolomite, or magnesite, if alkaline absorption is used). It is the only method which produces nitric acid directly and not through intermediary products as ammonia, calcium cyanamide, carbide, etc. It has, however, the disadvantage or requiring more electric energy per ton of fixed nitrogen, and thus far a higher plant investment than the purely chemical processes.

The reactions involved in the nitrogen fixation by the arc are:

In the arc:

$$N_2 + O_2 = 2NO \qquad (1)$$

In the cooling gas stream:

$$2NO + O_2 = 2NO_2 \qquad (2)$$

In absorption:

$$2NO_2 + H_2O = NO_3H + NO_2H \qquad (3)$$

Then, as secondary reaction:

$$2NO_2H = NO + NO_2 + H_2O \qquad (4)$$

and NO and NO_2 are again converted by equations (1) and (2), so that the final result is:

$$2N_2 + 5O_2 + 2H_2O = 4NO_3H \qquad (5)$$

Energy Required and Efficiency Obtained

The equation (1) requires per gram molecule of NO:

$Q = 21{,}600$ cal. $= 91.8$ kj. (kilo-joule) of energy.

All the other reactions set energy free. Thus the total resultant reaction, (5), *sets free*, per gram molecule of NO_3H

$$Q = 7330 \text{ cal.} = 31.2 \text{ kj.}$$

According hereto, 1 kw.-hr. should produce $3600 \div 91.8 = 39.2$ g. mol. NO, giving $39.2 \times 63 = 2470$ g. NO_3H, and thereby give back 1.34 kj. as heat energy.

An industrial output of 660 kg. of NO_3H per kw.-yr., or 75 g. per kw.-hr., which seems to be a good average efficiency of the big arc process nitrate plants, thus would represent, referred to equation (1), an efficiency of about 3 per cent, while, referred to the reaction (5), the efficiency obviously is negative.

If, however, we include, in the energy required for arc nitrification, the heat energy necessary to raise the gases to the arc temperature, and assume an average specific heat of air of 0.25, and an arc temperature of 3300 deg. abs., at an NO concentration of 4.35 per cent in the arc, an additional expenditure of energy, per g.-mol., would be required, of

$$500{,}000 \text{ cal.} = 2120 \text{ kj.}$$

One kw.-hr. thus would theoretically give only 103 g. NO_3H, and the commercial output of 75 g. per kw.-hr. thus would represent an efficiency of 73 per cent.

If the heating of the air occurs at constant volume, about 25 per cent less energy would be required, giving 136 g. per kw.-hr. With arcs very quickly started and moving, probably the heating occurs between constant pressure and constant volume conditions.

Furthermore, more or less of the temperature rise of the gases could, at least theoretically, be given by regeneration.

However, the heat energy required to raise the gases to the arc temperature depends on the arc temperature, which, at least theoretically, is not a fixed invariable quantity, and on the concentration in the arc stream, so that such efficiency calculations appear of little practical value and meaning.

Scientific Study Required

It may be of interest, therefore, to study further the theoretical side of the arc nitrification problem.

As I have been interested in the problem for many years, theoretically and experimentally, such a study was undertaken. Two considerations contributed.

During the late war practically unlimited means was available to create a nitrification industry in our country, producing nitric acid for the manufacture of high explosives. Nevertheless, when the armistice was signed after a year and a half of war, I believe not a single ton of nitric acid had been produced synthetically, showing the enormous difficulty of creating a new industry rapidly on the gigantic scale required for high explosives in modern war. If it thus had been a war of defense against invasion, and the supply of Chilean nitrate had been cut off by an enemy controlling the ocean, we would have been practically defenseless. The existence of a powerful nitrification industry in peace times, which may be deflected to war uses in emergency, thus is essential for our national safety. The only demand large enough to support such an industry in peace time is that for fertilizer. However, ammonia can be used directly as fertilizer. Thus the oxidation of ammonia to nitric acid would not be required by the peace requirements, and this essential step in the war industry would remain undeveloped. Therefore the arc method of nitrification would be safer for this purpose, as its product, nitric acid, is directly applicable to the high explosive manufacture

Furthermore, when looking into the problem of arc nitrification, it appeared that since the days of Koenig and Bradley very little general investigating has been done, and the development has all been in one direction, the use of high-power alternating arcs. Even the most fundamental data on arcs, and particularly the transient arcs used in nitrification, are very little known and uncertain, and it appears that the possibilities of development are much greater with the arc process than with any other nitrification process.

Reaction Velocity and Temperature Equilibrium

Starting with the meager available data, the reaction velocities, reaction time and thermal equilibrium conditions among oxygen, nitrogen and nitric oxide will be taken up; that is, the nitrifying action of the electric arc in air is considered and investigated as a thermal phenomenon.

The nitric oxide equilibrium concentration in air is extremely small, except at very high temperatures, and at the latter, the reaction velocity, and more particularly the dissociation velocity, is so enormous that it appears impossible to save any appreciable part of the nitric oxide from dissociation during the period of cooling, unless an extremely rapid cooling can be resorted to. The problem of thermal nitrogen fixation thus is essentially that of rapid cooling of the reacting gases.

With a given rate of cooling, or given cooling law, the maximum possible residual nitric oxide concentration, that is, the highest nitric oxide concentration in the air passing through the arc which can be saved, is limited to definite and not very high values, irrespective

of the reacting temperature in the arc, and irrespective thus of the initial nitric oxide concentration, provided the reaction temperature is higher than the equilibrium temperature of the residual concentration. Any material increase of the reaction temperature beyond the equilibrium temperature of the residual concentration possible by the cooling law thus offers no advantage, but is a waste of energy and thus of efficiency.

In the following some theoretical considerations on the arc process of nitrification are given. To a considerable extent obviously they must be of the nature of a review and very general.

In 1 g.-mol. of air, let the mol. fractions of nitrogen be n; oxygen, o; nitrogen oxides, a; and inert gas such as argon, b. Thus

$$n + o + a + b = 1 \qquad (6)$$

The normal composition of atmospheric air is $n = 0.777$; $o = 0.210$; $a = 0.000$; $b = 0.013$; so that the weight of a g.-mol. can be readily calculated from the molecular weights as follows:

Nitrogen	$= nN_2 = 0.777 \times 28 =$	21.76 g. per g. - mol. air
Oxygen	$= oO_2 = 0.210 \times 32 =$	6.72 g. per g. - mol. air
Argon	$= bAr = 0.013 \times 40 =$	0.52 g. per g. - mol. air
Air	$=$	29.00 g. per g. = mol. air

The volume of the g.-mol. then is, assumed as ideal gas, by $pV = RT$, in which atmospheric pressures, centimeters volume and Centigrade absolute temperatures are used.

$$V = \frac{RT}{p} = \frac{82 \times 273}{1} = 22{,}400 \text{ cc. (29 g. air)}$$

In the case of exhaust gases from an arc nitrogen fixation furnace having about 2 per cent nitric oxide content, the weight of a g.-mol. is as follows:

Nitrogen	$= 0.767 \times 28 =$	21.48 g.
Oxygen	$= 0.200 \times 32 =$	6.40 g.
Nitric oxide	$= 0.020 \times 30 =$	0.60 g.
Argon	$= 0.013 \times 40 =$	0.52 g.
Arced air	$=$	29.00 g.

Reaction Velocities

The velocity of combination of nitrogen and oxygen to NO may be expressed:

$$v_1 = c_1 no \qquad (7)$$

where the formation velocity constant c_1 is a function of the absolute temperature T of the reaction.

The velocity of dissociation of NO is similarly expressed:

$$v_2 = c_2 a^2 \qquad (8)$$

where the dissociation velocity constant c_2 is likewise a function of the absolute temperature T.

The rate of increase of NO is the resultant between v_1 and v_2 and is expressed

$$v = \frac{da}{dt} = v_1 - v_2 = c_1 no - c_2 a^2 \qquad (9)$$

In these equations there are three variables, n, o and a. It is frequently more convenient to denote

n_o = initial nitrogen concentration = 0.777

o_o = initial oxygen concentration = 0.210

and as

$$n = n_o - \frac{a}{2}$$

$$o = o_o - \frac{a}{2} \qquad (10)$$

the equations can be reduced to the single variable a,

$$v_1 = c_1 \left(n_o - \frac{a}{2}\right)\left(o_o - \frac{a}{2}\right) \qquad (11)$$

$$v = c_1 \left(n_o - \frac{a}{2}\right)\left(o_o - \frac{a}{2}\right) - c_2 a^2 \qquad (12)$$

Equilibrium Constants

When the rates of dissociation and combination are equal, equilibrium is reached.

$$v = c_1 no - c_2 a^2 = 0$$

$$C = \frac{c_1}{c_2} = \frac{a^2}{no} = \frac{a^2}{\left(n_o - \frac{a}{2}\right)\left(o_o - \frac{a}{2}\right)} \qquad (13)$$

or, more conveniently,

$$\frac{\sqrt{C}}{\sqrt{no}} = \frac{a}{\sqrt{\left(n_o - \frac{a}{2}\right)\left(o_o - \frac{a}{2}\right)}} \qquad (14)$$

The equilibrium constant C is a function of the absolute temperature T.

C, c_1 and c_2 are the equilibrium and reaction velocity constants denoted by K and k_1 and k_2 by Nernst and others, but reduced to the second as unit of time, as the second has since become the absolute time unit, while k, etc. is usually given with the minute as time unit. Thus, $C = K$, but $c = \frac{1}{60} k$. Compared with c_2, c_1 is a small quantity, the more so the lower the temperature.

The equilibrium constant C is given by van't Hoff's equation:

$$\frac{d \log_e C}{dT} = \frac{Q}{RT^2} \qquad (15)$$

where the heat of formation of NO, Q, = — 21,600 cal. Q is claimed to be independent of the temperature and the integration of equation (15) is

$$\log_e C_2 - \log_e C_1 = \frac{Q}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) = \frac{Q}{R}\left(\frac{T_1 - T_2}{T_1 T_2}\right) \qquad (16)$$

$$C_1 = C_2 e^{\frac{Q}{R}\left(\frac{T_1 - T_2}{T_1 T_2}\right)} \qquad (17)$$

From (16) substituting 21,600 for $\frac{Q}{R}$

$$\log_e C_1 = \log_e C_2 + \frac{21{,}600}{T_2} - \frac{21{,}600}{T_1} \qquad (18)$$

$$\log_{10} C_1 = \log_{10} C_2 + \frac{9380}{T_2} - \frac{9380}{T_1} \qquad (19)$$

As the average of the three determinations of Nernst gives

$$\log_{10} C = 1.048 - \frac{9380}{T} \qquad (20)$$

$$\log_e C = 2.413 - \frac{21{,}600}{T}$$

$$C = 11.17 e^{-\frac{21{,}600}{T}} \qquad (21)$$

From equation (14) then follows the equilibrium concentration

$$\sqrt{C} = \frac{a_o}{\left(n_o - \frac{a_o}{2}\right)\left(o_o - \frac{a_o}{2}\right)} = 3.34 e^{-\frac{10{,}800}{T}} \qquad (22)$$

Dr. Noyes gives $\log_{10} C = 1.091 - \frac{9426}{T}$. At 2000 deg. abs. this gives a difference of 8 deg. The values of a differ slightly from those given elsewhere, as in the latter the composition of air is approximated by $n_2 : o_2 = 80 : 20$ and equation (22) approximated by $\sqrt{C} = \frac{a_o}{n_o o_o}$

From Jellinek's data is calculated, by the $\Sigma\ \Delta$ method[2], the empirical equation of the dissociation velocity constant[3]:

$$\log_{10} C_2 = \bar{9}.113 + 5.731\ T\ 10^{-3} \qquad (23)$$

$$c_2 = 12.97e^{.0132\ T} \times 10^{-12} \qquad (24)$$

From (13) follows:

$$\log_{10} c_1 = \log_{10} C + \log_{10} c_2$$

thus substituting (20) and (23)

$$\log_{10} c_1 = 0.161 + 5.731\ T \times 10^{-3} - \frac{9380}{T} \qquad (25)$$

The equation $\log_{10} C = 0.814 - \frac{9460}{T}$, suggested by A. Wolokitin from hydrogen combustion, is hardly acceptable.

In Table I are given, for temperatures from 800 to 4200 deg. abs., the values of $\log_{10} C$, $\log_{10} c_1$, $\log_{10} c_2$, $\sqrt{C}$ c_2, c_1 and a_o calculated by the equations (20), (23), (25) and (22) for air with the composition, N : O : A = 0.777 : 0.210 : 0.013. In Fig. 1, the first four of these values are plotted.

If n, o, a, are the initial concentrations per g.-mol. at time t = zero, at constant temperature T, of N_2, O_2 and NO, differing from their equilibrium values, and n_o, o_o, a_o are these equilibrium values, and if at time t the NO concentration has increased by x (where x is negative, if $a > a_o$), the N_2 and O_2 concentrations have decreased to $\left(n - \frac{x}{2}\right)$ and $\left(o - \frac{x}{2}\right)$ respectively, when

$$\frac{dx}{dt} = c_1 \left(n - \frac{x}{2}\right)\left(o - \frac{x}{2}\right) - c_2\ (a + x)^2 \qquad (26)$$

[2]See "Engineering Mathematics," by author.

[3]From the same data Dr. Noyes calculates the equation (reduced to seconds):

$$\log_{10} c_2 = 9.253 + 5.635T$$

This gives a difference at 2000 deg. abs. of 9 deg.

∞	1.048	∞	∞	3340	∞	∞	37.6

Rearranged this equation gives:

$$\frac{dx}{dt} = (c_1 no - c_2 a^2) - 2x\left[c_2 a + \frac{c_1}{4}(n + o)\right] - \left(c_2 - \frac{c_1}{4}\right)x^2$$

or:

$$dt = \frac{-dx}{\left(c_2 - \frac{c_1}{4}\right)\left[x^2 + 2x\,\frac{c_2 a + \frac{c_1}{4}(n - o)}{c_2 - \frac{c_1}{4}} - \frac{c_1 no - c_2 a^2}{c_2 - \frac{c_1}{4}}\right]}$$

$$= \frac{-dx}{\left(c_2 - \frac{c_1}{4}\right)(x - x_1)(x - x_2)}$$

where x_1 and x_2 are the roots of the equation:

$$x^2 + 2x\,\frac{c_2 a + \frac{c_1}{4}(n + o)}{c_2 - \frac{c_1}{4}} - \frac{c_1 no - c_2 a^2}{c_2 - \frac{c_1}{4}} = o \qquad (27)$$

and are:

$$\left.\begin{matrix} x_1 \\ x_2 \end{matrix}\right\} = \frac{-1}{c_2 - \frac{c_1}{4}}\left[c_2 a + \frac{c_1}{4}(n + o) \pm S\right] \qquad (28)$$

where:

$$S = \sqrt{\frac{c_1}{4} c_2\, 4no + 2a(n + o) + a^2 + \frac{c_1}{4}(n - o)^2} \qquad (29)$$

thus:

$$dt = \frac{-dx}{\left(c_2 - \frac{c_1}{4}\right)(x_1 - x_2)}\left[\frac{1}{x - x_1} - \frac{1}{x - x_2}\right] \qquad (30)$$

and:

$$t = \frac{1}{\left(c_2 - \frac{c_1}{4}\right)(x_1 - x_2)} \log_e \frac{x_1\,(x - x_2)}{x_2\,(x - x_1)} \qquad (31)$$

and, by (29):

$$t = \frac{1}{2S} \log_e \frac{x_1\,(x - x_2)}{x_2\,(x - x_1)} \qquad (32)$$

is the *reaction time*, that is, the time required to change the NO concentration by x, or from a to $a + x$.

Special Cases

Dissociation of pure NO to half of its value:

$$n = 0;\ o = 0;\ a = 1;\ x = -0.5 \qquad (33)$$

For convenience, reversing the sign of x in equations (26) to (32).

In substituting (33) in (26) to (32), and neglecting c_1 compared with c_2, as a small quantity:

$$S = 0.5\sqrt{c_1 c_2}$$

$$\left.\begin{matrix} x_1 \\ x_2 \end{matrix}\right\} = +\left(1 \pm 0.5\sqrt{\frac{c_1}{c_2}}\right)$$

$$t = \frac{1}{\sqrt{c_1 c_2}} \log_e \frac{1 - x + 0.5\,x\sqrt{\frac{c_1}{c_2}}}{1 - x - 0.5\,x\sqrt{\frac{c_1}{c_2}}}$$

$$= \frac{1}{\sqrt{c_1 c_2}} \log_e \frac{1 + \frac{0.5\,x}{1-x}\sqrt{\frac{c_1}{c_2}}}{1 - \frac{0.5\,x}{1-x}\sqrt{\frac{c_1}{c_2}}}$$

and, since $\frac{c_1}{c_2}$ is a small quantity (Engineering Mathematics), the $\log_e$ becomes:

$$\frac{x}{1-x}\sqrt{\frac{c_2}{c_1}}$$

thus:

$$t = \frac{x}{(1-x)c_2} \qquad (34)$$

and for: $x = 0.5$

$$t_2 = \frac{1}{c_2} \qquad (35)$$

or:

$$c_2 = \frac{1}{t_2} \qquad (36)$$

TABLE II. THERMAL REACTION TIMES

T_1 Deg. Abs.	t_2 Dissociation Time of NO to half value		t_1 Formation Time of Air to half equilibr.		t_3 Dissociation Time Air, 200 Deg. Drop

3,200	0.0353	....	0.420	....	0.0632	....
3,400	2,520 micro sec.	....	0.0245	....	3,230 micro sec.	
3,600	180	....	1,470 micro sec.	...	175	
3,800	12.9	....	89.7	....	9.75	....
4,000	0.917	....	5.56	....	0.58	....
4,200	0.0658	....	0.349	....	....	....

This permits to determine c_2 from the reaction time t_2.

Nitrification of Air to half the equilibrium value:

$$n = 0.777;\ o = 0.21;\ a = 0;\ x = \frac{a_o}{2} \qquad (37)$$

Substituting (37) into (26) to (32), neglecting c_1 compared with c_2, and also neglecting $\frac{x}{2}$ compared with n and o, it is:

$$S = \sqrt{c_1 c_2 n o}$$

$$\left.\begin{matrix} x_1 \\ x_2 \end{matrix}\right\} = \pm\frac{1}{c_2} S = \pm\sqrt{\frac{c_1}{c_2}}\, no = \pm\sqrt{Cno}$$

and since:

$$C = \frac{a_o}{no}$$

it is:

$$\left.\begin{matrix} x_1 \\ x_2 \end{matrix}\right\} = \pm a_o$$

thus:

$$t = \frac{1}{2\sqrt{c_1 c_2 n o}} \log_e \frac{a_o + x}{a_o - x} \qquad (38)$$

and for half equilibrium value, $x = \frac{a_o}{2}$:

$$t_1 = \frac{1}{2\sqrt{c_1 c_2 n o}} \log_e 3 \qquad (39)$$

TABLE III. THERMAL NITRIFICATION VELOCITIES IN AIR

Thus:

$$t_1 = \frac{1.36}{\sqrt{c_1 c_2}} \qquad (40)$$

is the reaction time producing half the equilibrium value of NO in the air.

Dissociation of NO in air from a_1 corresponding to previous temperature T_1, at lower temperature T_2, giving a_2, to half the approach to a_2, that is, to $\frac{a_1 + a_2}{2}$.

$$n = 0.777 - \frac{a_1}{2};\ o = 0.21 - \frac{a_1}{2};\ a = a_1;\ x = \frac{a_1 - a_2}{2}; \qquad (41)$$

sign of x reversed, c_1 and c_2 correspond to temperature T_2.

Substituting in equation (26) to (32), and neglecting small quantities:

$$S = 1.1 c_1 c_2 no$$

$$\left.\begin{matrix} x_1 \\ x_2 \end{matrix}\right\} = \frac{-1}{c_2}\left[c_2 a_1 \pm S\right]$$

$$t = \frac{1}{2S}\log_e \frac{(c_2 a_1 - S)(c_2 a_1 + S - c_2 x)}{(c_2 a_1 + S)(c_2 a_1 - S - c_2 x)}$$

$$= \frac{1}{2S}\left[\frac{2S}{c_2 a_1 - c_2 x} - \frac{2S}{c_2 a_1}\right]$$

thus:

$$t = \frac{x}{c_2 a_1 (a_1 - x)} \qquad (42)$$

and for:

$$x = \frac{2}{a_1 - a_2}$$

$$t = \frac{a_1 - a_2}{c_2 a_1 (a_1 + a_2)} \qquad (43)$$

Thus for: $T_1 = 3840$; $a_1 = .072$

$T_2 = 2580$; $a_2 = .020$; $c_2 = 7400$

$t_2 = 1.06 \times 10^{-5}$

$= 1.06$ milliseconds.

Table II gives

t_2, the dissociation time of pure NO to half value, from (35)

t_1, the formation time of air to half equilibrium, from (40)

t_2, the dissociation time of air at 200 deg. drop, for T_2, from (43).

Table III gives the reaction velocities in air:

$$v = \frac{dx}{dt} = c_1\left(n - \frac{x}{2}\right)\left(o - \frac{x}{2}\right) - c_2 x^2 \qquad (26)$$

where: $n = .777$; $o = .210$ are the initial N_2 and O_2 concentrations respectively, and x is the NO concentration, for temperatures from 1400 to 4000 deg. abs., and NO concentrations from $x = 0$ to $x = 40$ per cent.

The second part of the table, for high concentration of NO, is calculated by the approximation permissible in this case:

$$v = -c_2 x^2$$

(*Part II will be published in our next issue*)

Forest Products Laboratory in Australia

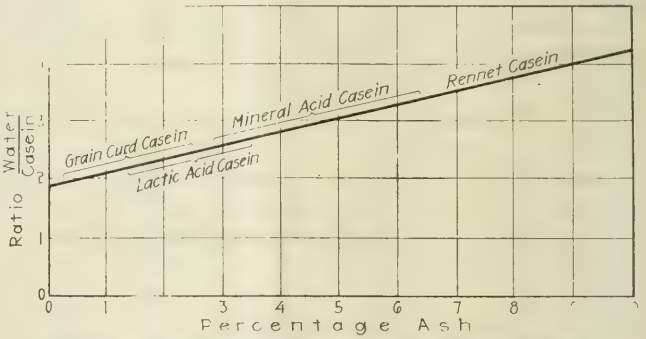
A forest products laboratory is about to be established in Australia in connection with the Perth Technical School at Perth, for the purpose of experimenting in the utilization of the byproducts of Australian timber mills and forests. I. H. Boas of the faculty of chemistry of Perth has been sent to the U. S. to conduct inquiries. He will visit the laboratories at Madison, Wis., at Montreal, and elsewhere.

Notes on Casein Glue*

It has been determined that formaldehyde used in some manufacturing processes to coagulate casein is not successful for rendering casein glue less soluble.

Discoloration of casein on heating to 212 deg. F. (100 deg. C.) is due to the presence of lactose and indicates that the curd was not very thoroughly washed. Absence of such color change indicates well-washed curd, except in the case of natural sour casein precipitated from very sour milk. In this case no discoloration is noticed, because all the lactose has been converted into lactic acid.

Proof of the value of animal, vegetable, casein and blood albumin glues as binding agents has been shown by soaking for 20 weeks in gasoline, engine oil and



ASH-WATER ABSORPTION CURVE FOR MEDIUM VISCOSITY CASEIN GLUES

castor oil, the results showing no separation of the plies. Shear tests, however, gave evidence that a gradual weakening of the glue proceeds under this treatment. The loss in strength, however, was in no case as much as would be caused by the standard test of soaking for 10 days in water.

Experiments have shown that all caseins of a reasonable degree of purity can be made into satisfactory glues by the same formula simply by varying the amount of water used.

Caseins may be divided into definite groups according to the amount of water which they require to make glue of a given consistency. This grouping is roughly the same as that according to methods of casein manufacture. Grain-curd casein requires the least water; lactic-acid casein, ordinary mineral-acid casein, and rennet casein increasingly larger amounts.

The ash content of these caseins also increases in the same order. In fact, the relation between the ash content and amount of water required is so close that if the former is known the latter may be predicted. The relation between the ash content and the water requirement may be expressed by such an equation as

$$y = mx + b$$

wherein x is the ash content of the casein, y the water-casein ratio required to give a glue of medium viscosity, and m and b constants depending upon the formula used. This gives a straight line, as shown in the diagram.

The most essential constituent used in casein to produce the casein water-resistant glue is lime. The purity of the commercial lime is not a determining factor in glue-making. When a lime of unknown analysis is to be used, it is desirable to begin with an amount which would give a glue of short- or medium-working life and a satisfactory flow. It is essential in the use of new lime that tests of the water-resistant glue products should be made as soon as possible.

Stack Losses at Arizona Copper Co.

By J. Owen Ambler*

THE following data taken from a report submitted by the Western Precipitation Co., of Los Angeles, Cal., to Norman Carmichael, general manager of the Arizona Copper Co., Ltd., of Clifton, Ariz., show the methods and apparatus used and the results attained in testing for fume loss at the smelter of the company, and are of general interest as showing the application of the Cottrell system to this class of work. The experiments were made in 1916 and 1917.

General Method of Test

A plan of the flue system (Fig. 1) indicates the points at which samples were taken for the various departments, and during the course of the tests operating conditions were varied so that as wide a range as possible was covered. The points chosen for the tests were located so that a fairly long passage of about the same cross-section preceded the sampling, in order that the velocity figures might be as accurate as possible.

Gas samples and velocity measurements were taken at fixed points in the cross-section of the flues, explorations of this section having been made previously to determine the ratio of the velocity at the fixed point to the average over the entire flue. The entire volume passing the section was calculated from this ratio and the Pitot tube measurements of the velocity.

The volume of the gas sample was measured by a Pitot tube located in the inlet pipe between the flue and the treater, while the dust caught was collected after

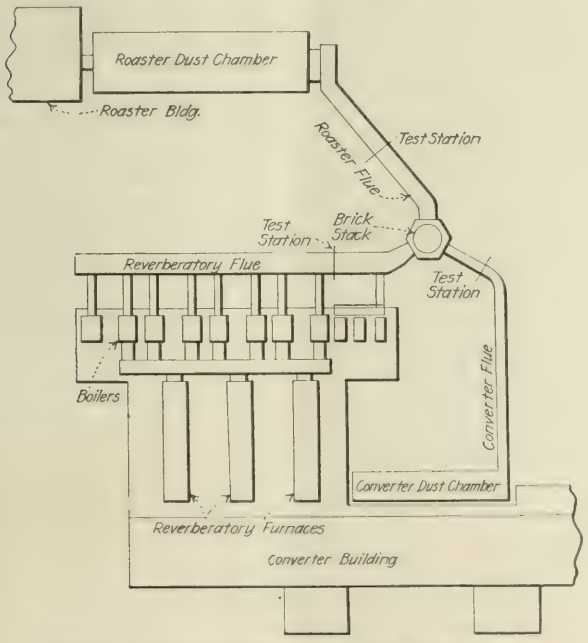

FIG. 1. PLAN OF THE FLUE SYSTEM

each run, weighed and analyzed. The weight of dust per cu.ft. of gas and the measured flue velocity were used to determine the total fume loss for the particular test.

Separation of the dust of fume from the flue gas was effected by electric precipitation in a Cottrell treater consisting of a vertical 12-in. iron pipe (the collecting electrode) in which was suspended an iron wire (the discharge electrode). A high voltage unidirectional potential was maintained between these electrodes by means of a step-up transformer and a disk type rectifier. As is well known, when the gases with their suspended particles were passed through this treater the particles became charged, and, due to the electric field, moved to the collecting electrode, where they were deposited, the gases passing through unaffected. At the completion of a test the pipe was jarred by a blow, which caused the dust to drop to the bottom of the treater, where it was collected and weighed.

Pitot tubes used in this investigation consisted essentially of two parts, one to receive the static pressure

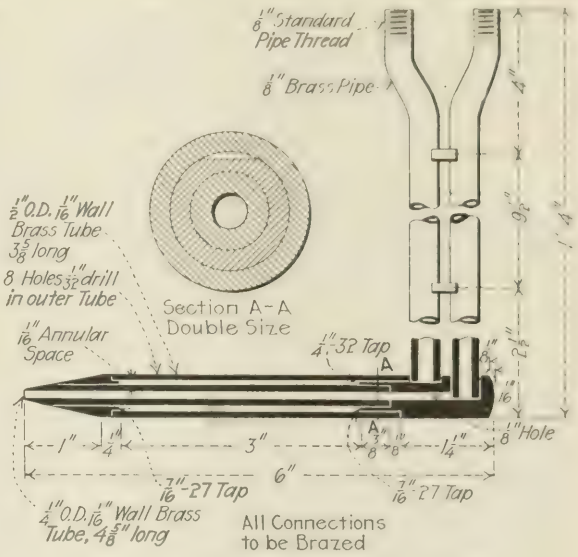

FIG. 2. DETAILS OF PITOT TUBE

and the other to receive the sum of the static and velocity pressures, the outlets from these two parts leading to the opposite ends of the gage which registered the differential pressure indicating the velocity head. The tube used was that known as the American Blower Co. type, and is shown in detail in Fig. 2. Static openings consist of small drill holes in the side of the outer sheath, and the impact opening is the end of the tube, beveled to a sharp edge. It is possible, with this type of tube and an accurate gage, to obtain an accuracy of 1 per cent, though this degree is seldom attained in general work, due to certain uncontrollable gas conditions.

Working Formula

Since in its operation the Pitot tube follows the law of falling bodies, $V^2 = 2gh$, where h is the head of fluid producing the velocity V, a working formula was developed as follows:

Let
T = absolute temperature of flowing gas, deg. F.
K = absolute temperature of flowing gas, deg. C.
P = absolute pressure of flowing gas, lb. per sq.in.
B = absolute pressure of flowing gas, in. of mercury.
d = weight per cu.ft. flowing gas at the given temperature and pressure.
G = specific gravity of flowing gas. (air = 1.)
V = actual velocity of flowing gas, ft. per sec.
h_f = height in feet of homogeneous column of gas, at given temperature and pressure, which produces V.
h = corresponding height of water column in in.
d_w = weight per cu.ft. of water = 62.37 lb. at 60 deg. F.
d_a = weight per cu.ft. of air at 32 deg. F. and 14.7 lb. = 0.08073 lb.
g = acceleration due to gravity = 32.16.

*Smelter Superintendent.

$$\text{Then, } V = \sqrt{2gh_f} = \sqrt{\frac{2ghd_w}{12d}}, \text{ since } dh_f = \frac{hd_w}{12}.$$

$$\text{But } d = d_a \times G \times \frac{P}{14.7} \times \frac{491.2}{T}$$

$$\text{Therefore, } V = \sqrt{\frac{2g\,hd_w\,14.7T}{12d_a\,491.2PG}} =$$

$$\sqrt{\frac{2 \times 32.16 \times 62.37 \times 14.7 \times hT}{12 \times .08073 \times 491.2 \times P \times G}} =$$

$$\sqrt{\frac{123.9hT}{PG}} = 15.88\sqrt{\frac{hT}{BG}} = 21.30\sqrt{\frac{hK}{BG}}$$

The pressure gages were of the standard Ellison type, and both ordinary and recording mercury type thermometers were used, care being taken to insulate the treater intake pipe carefully with magnesia covering, so that the temperature taken in the intake pipe could be used both for the flue and intake temperatures.

Typical Data on Roasting Flue

A typical set of determinations in a test of the roaster flue, showing data taken and methods of calculation of results, follows:

Average velocity intake pipe	=	0.905 velocity at point of measurement
Average velocity flue	=	0.934 velocity at point of measurement
Flue velocity head	=	0.0223 in. water
Temperature	=	359.0 deg. C. abs.
Intake velocity head	=	0.1207 in. water
Barometer	=	26.47 in.
Amount dust collected	=	3607 g.
Time of test	=	920 min.
Density of gas	=	1.02
Percentage copper in dust	=	5.71

For this case with the barometer 26.47 in. of mercury the flue velocity will be:

$$21.30\sqrt{\frac{.0223 \times 359}{26.47 \times 1.02}} = 11.59 \text{ ft. per sec.}$$

Similarly the intake velocity will be:

$$21.30\sqrt{\frac{.1207 \times 359}{26.47 \times 1.02}} = 26.95 \text{ ft. per sec.}$$

Let t be the time in minutes and let v_t be the velocity in feet per second at the point of measurement in the 6-in. dia. intake pipe. The volume passing this point will be, since the average velocity is 0.905 of the velocity at point of measurement:

$$0.905 \times v_t \times \pi \times \tfrac{1}{16} \times 60 \times t = 10.68tv_t$$

$$\text{Volume of sample} = 10.68 \times 26.95 \times 920 = 265{,}000 \text{ cu.ft.}$$

$$\text{Weight of dust per cu. ft.} = \frac{3607}{265{,}000} = 0.01360 \text{ g. per cu. ft.}$$

By Pitot tube explorations of the flue the average velocity was found to be 0.934 times the velocity at the point of measurement. The dust level in the flue was determined at the beginning and completion of the test and the mean area at the section for sampling was found to be 142.5 sq.ft. If v_f is the recorded flue velocity in feet per second, the volume of gas in cubic feet per minute will be

$$142.5 \times 0.934 \times v_f \times 60 = 8{,}000v_f,$$

and total weight of dust in pounds per 24 hr. will be

$$8{,}000 \times 1{,}440 \times \text{g. dust per cu.ft.} \times v_f \times 0.002205 = 25{,}400v_f \text{ g. dust per cu.ft.}$$

By substitution, the total dust loss in roaster flue then equals

$$25{,}400 \times 11.59 \times 0.01360 = 4{,}020 \text{ lb. in 24 hr.,}$$

and the total copper loss equals

$$4{,}020 \times 5.71 \text{ per cent} = 229 \text{ lb. in 24 hr.}$$

SUMMARY OF ALL TESTS

Roasters:	Normal Draft	High Draft
Average flue velocity in ft. per sec.	11.4	20.41
Average volume of gas at flue temperature, cu.ft.	91,200	163,300
Average temperature at sampling pipe, deg. F.	186	212
Average copper content of dust, per cent	5.65	5.41
Average dust loss per 24 hr., lb.	4,375	10,572
Average copper loss in 24 hr., lb.	247	571

	Operating Two Converters		Operating Three Converters
Converters:	High Draft	Normal Low Draft	High Draft
Average flue velocity, ft. per sec.	50.2	35.2	50.3
Average volume gas at flue temperature, cu.ft.	136,200	95,800	136,900
Average temperature at sampling pipe, deg. F.	349	375	400
Average copper content of dust, per cent	12.9	5.62	10.7
Average tons copper cast per 24 hr.	79.6	72.25	92.0
Average dust loss per 24 hr., lb.	1,738	1,252	2,935
Average copper loss per 24 hr., lb.	225	70.5	314

Reverberatories:	Normal Draft
Average flue velocity, ft. per sec.	19.01
Average volume gas at flue temperature, cu.ft.	259,500
Average temperature at sampling pipe, deg. F.	310
Average copper content of dust, per cent	3.58
Average tons dry solid charge treated per 24 hr.	810
Average dust loss per 24 hr., lb.	9,363
Average copper loss per 24 hr., lb.	336

Roasters	247.0
Reverberatories	336.0
Converters	70.5
Total	653.5

Corporation Patriotism

Speaking at the American Electric Railway Association dinner in Cleveland on Jan. 8, Senator Harding gave the following intimate account of the way in which the du Pont organization served the War Department in the construction of powder plants.

"When America entered the war we were making in this country approximately two-thirds of all the powder used by the Allied Governments. We declared war in April, 1917, and it was nine months after the declaration before we contracted for the production of American powder to participate in the war.

"The reason was that the authorities did not want to tie up with what they termed big business, and nine months were wasted before a stroke was made, until finally the du Ponts were authorized to build a Federal powder plant at Nashville, Tenn. They were commissioned to build a plant that would produce 500,000 lb. of powder per day, and if they finished the plant and had it in running order by July 1, 1918, they were to receive a commission of $3,500,000 for the service rendered. They worked so effectively that the plant was in partial operation in June.

"The Secretary of War then called in their agents and said: 'We want to duplicate the plant. We will duplicate that contract and will extend the time to October. We want a million-pound capacity plant. Your commission will be $7,000,000 all told. Can you do it?' The spokesman for the company said: 'Yes, on one condition—that you will take out your pestiferous, uninformed, annoying inspectors, and let us do the job. We will promise you we will join in prosecuting every crook that appears on the scene, and if you will just let us do it, we will tear up our contract, and charge you not one cent bonus.'

"The Secretary of War said: 'You don't mean it?' And the spokesman said: 'We do mean it; is it a go?' The Secretary of War answered: 'Yes,' and the spokesman of the company said: 'I will tear up the contract, and $7,000,000 is our contribution toward helping the war along.'"

Some Developed Mineral Resources and Chemical Industries of the Southern States*

Review of the Southern Fertilizer Resources—Phosphate Rock, Mining, Grinding, Acidifying and Mixing Into Commercial Fertilizer—Mining of Sulphur, Pyrites and Pyrrhotite—Manufacture of Sulphuric Acid—Smelting of Copper

By ANDREW M. FAIRLIE

PHOSPHATE rock has been grouped here with three apparently unrelated minerals obviously because of the interdependence of the respective manufactured products—acid phosphate and sulphuric acid.

The object in preparing this paper is to present, in compact form, before the Institute at this meeting, held in a city of the South, some of the salient facts, already well known probably to those familiar with the subjects, pertaining to these rather prominent industries of the Southern states. A realization of what has been done in these fields of endeavor may serve as some indication of what may yet be accomplished in other fields, still undeveloped.

The term "phosphate rock" includes the calcium phosphates, of which apatite has probably the most definite and constant composition. Two varieties of apatite are recognized, namely, fluorapatite, $Ca_5(PO_4)_3F$, and chlorapatite, $Ca_5(PO_4)_3Cl$. Other phosphatic minerals are manganapatite, hydroapatite, "phosphorite," staffelite, and pseudoapatite.

A concise statement of the origin of phosphate rock, together with a description of the methods of mining (both underground and open pit), and an outline of washing and drying methods for the elimination of impurities and the preparation of the rock for the market, will be found in an article entitled "Phosphate," by E. H. Sellards,[1] obtainable from the State Geologist, Tallahassee, Fla.[2]

The United States, with a production in 1913 (the latest wholly pre-war year) of 3,111,221 long tons of phosphate rock, or practically one-half of the production of the entire world, leads all other countries as a producer of that mineral. All of this country's production, with the exception of 5,053 tons, was produced in the Southern states[3]; and Florida, with an output of 2,545,276 long tons, and Tennessee, with 451,559 long tons, together produced over 96 per cent of the entire output of the country. The only other phosphate-producing states worthy of mention are South Carolina and Kentucky, and the production in the latter state, as late as 1917, amounted to only a few thousand tons. The deposits of South Carolina were the first to be mined in America.[4] Phosphate rock has been mined in past years in Arkansas, but the production in this state has apparently stopped. Phosphatic minerals or marls are known to exist in four other Southern states—Virginia, North Carolina, Alabama and Georgia—and brief descriptions of these various deposits will be found in the paper by Sellards,[5] referred to previously.

On account of the preponderating influence on the market of the production from the states of Florida and Tennessee, the following extracts from Sellards' paper, with reference to the deposits of these two states, may be of interest.

Phosphate Deposits of Florida

"The phosphate produced in Florida includes two kinds, namely, hard rock and land pebble phosphates.

"The matrix in which the hard rock phosphate is imbedded is extremely variable. The formation includes a mixture of materials from various sources and of the most diverse character, further complicated by pronounced chemical activity within the formation itself. The prevailing phase of the formation is feebly coherent, more or less phosphatic, light gray sand. Aside from these sands the principal materials of the formation are clays, phosphate rock, flint boulders, limestone inclusions, pebble conglomerate, erratic and occasional waterworn flint pebbles, vertebrate and invertebrate fossils, and occasional pieces of silicified tree trunks.

"Phosphate rock, although the constituent of special economic interest, nevertheless makes up a relatively small part of the formation. The phosphate in these deposits occurs as fragmentary rock, boulder rock, plate rock, or pebble. The boulders are often of large size, in some instances weighing several tons, and must be broken up by blasting before being removed from the pit. It is also necessary to operate a rock crusher in connection with all hard rock phosphate mines to reduce the larger pieces of rock to a size suitable for shipping. The relative amount of material that it is necessary to handle to obtain a definite amount of phosphate is always variable with each pit and with the different parts of any one pit. The workable deposits of phosphate lying within this formation occur very irregularly. While at one locality the phosphate may lie at the surface, elsewhere it may be so deeply buried as not to be economically worked; while a deposit once located may cover more or less continuously a tract of land some acres in extent, elsewhere a deposit, appearing equally promising on the surface, may in reality be found to be of very limited extent. As to location, depth from surface, extent into the ground, lateral extent, quantity and quality, the hard rock phosphate deposits conform to no rule. The desired information

*Read before the American Institute of Chemical Engineers, Savannah, Ga., Dec. 6, 1919.

[2]Acknowledgment of indebtedness to Dr. Sellards' paper is here made for much of the data regarding the phosphate minerals and the distribution of phosphate rock, etc., repeated here.

[3]W. C. Phalen, "The Production of Phosphate Rock in 1913." Mineral Resources of the United States, Part II, 1914, p. 273.

[4]According to Sellards, actual mining began in 1867.

[5]*Op. cit.*, p. 86.

is to be obtained only by extensive and expensive prospecting and sampling.

"The materials above the phosphate deposits include pale yellow incoherent sand and in some localities clayey sand. The incoherent sands are variable, an average thickness being from 5 to 15 ft., although as much as 30 ft. have been observed.

"The land pebble phosphates of southern Florida are much more uniform in their manner of occurrence than are the hard rock deposits. The phosphate is in the form of pebble rock imbedded in a matrix of clay, sand and soft phosphate. Although variable from place to place, the phosphate bed has an average thickness of from 8 to 10 ft., its maximum thickness being from 18 to 20 ft. The overburden, which consists largely of sand and sandy clays, with local indurated or calcareous ledges, has an average thickness of from 10 to 14 ft.

"The best grade of land pebble rock, when properly washed, dried and selected, permits a guarantee of 75 or 76 per cent tricalcium phosphate. Other grades on the market range from 62 to 75 per cent. The hard rock phosphates range from 79 to 83 per cent, although selected samples run as high as 84 or 85 per cent tricalcium phosphate.

"Practically all of the hard rock phosphate mined in Florida is exported. Of the land pebble phosphate produced, over 40 per cent was exported in 1913.

Phosphate Deposits of Tennessee

"In Tennessee several more or less distinct types of phosphate occur, only two of which, however, blue rock and brown rock, are being mined at present. The blue phosphate occurs as a bedded deposit within, but forming the lowest member of, the Chattanooga formation of the Devonian age, and resting directly upon Ordovician limestone. The blue phosphates are said to vary in grade from about 30 to 85 per cent tricalcium phosphate. Iron and aluminum in the better grade of rock aggregate less than 3 per cent. The beds vary in thickness from 0 to 50 in., although the bed furnishing high-grade rock rarely exceeds 20 in. in thickness.

"The brown rock of Tennessee is at the present time (1914) of greater commercial importance than the blue rock. This rock occurs in irregular deposits lying near the surface and resting on limestone. The overburden consists usually of residual material including clay, some phosphate, and a limited amount of sand. Its thickness is extremely variable, although averaging 8 or 10 ft. The phosphate consists of a shelly rock, breaking up into pieces of varying size, and of small variegated pebbles which in mass have a dark brown color. Locally the small pebble rock predominates, forming a scarcely coherent mass having a brownish color. A phase of the material, known locally as 'muck' deposit, consists of a mass of small pebbles, often not exceeding a pinhead in size."

TABLE I. PHOSPHATE ROCK MARKETED IN AND EXPORTED FROM THE UNITED STATES, 1913–1917

Year	Proportion of Exports to Domestic Production (Per Cent)	Marketed Production (Long Tons)	Exports (Long Tons)
1913	44	3,111,221	1,366,508
1914	35	2,734,043	964,114
1915	14	1,835,667	253,421
1916	12	1,982,385	243,678
1917	6	2,584,287	166,003

The phosphate deposits of Tennessee are in the central part of the state. According to J. S. Hook, the centers of production lie in Maury, Hickman, Lewis, and Giles counties. The most important deposits are those in the vicinity of Mount Pleasant, in Maury county, eleven miles southwest of Columbia, the county seat. Further information regarding the phosphate rock deposits of Tennessee can be found in the April (1914) issue of "The Resources of Tennessee."[6]

Extensive deposits of phosphate rock are known to exist in Utah, Idaho, and other Western states, but as late as 1917 the West produced only 0.6 of 1 per cent of the entire output of the country for that year. That the output for 1917 (15,096 tons) represented an increase of 786 per cent over the production for 1916 indicated, however, a tendency toward increased activity in that section.

Table I[7] illustrates in eloquent manner the marked effect of the European war on the phosphate industry of this country.

The rapid decline in the exports of phosphate rock from this country is shown graphically on the accompanying diagram (Fig. 1).

Naturally, as Florida is the largest producer of phosphate rock, the brunt of the stagnation of the export business was borne by that state. The summary[8] of the shipments of phosphate rock from Florida from 1913 to 1918, inclusive, (Table II) is interesting, in comparison with Table I.

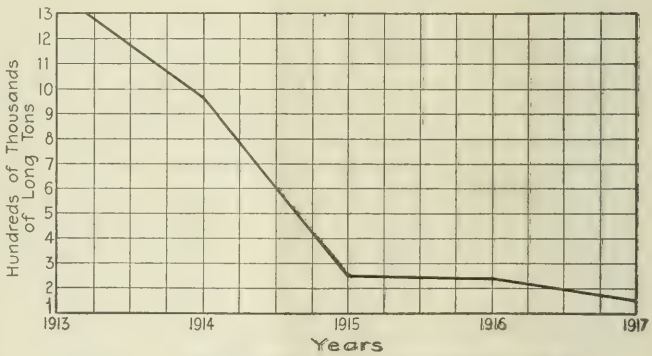

FIG. 1. EXPORTATION OF PHOSPHATE ROCK

It is apparent, from statistics furnished by the United States Department of Commerce, that during the first half of 1919 the export business in phosphate rock showed some signs of improvement. Exportations of phosphate rock for the fiscal year ended June 30, 1919, are given in Table III.

It will be noted that all of these statistics refer to shipments. The shipment tonnages are never the same as the tonnages of rock mined, for there are variable amounts in storage at the end of each year. The tonnage of rock mined in 1918 shows a decrease of 443,247 long tons from that mined in 1917, the diminished output being a reflection of conditions due to our entry into the war, such as difficulty in securing labor, restrictions placed on fuel distribution and shipping facilities, etc.

* Includes soft rock phosphate.

The total value of the shipments in 1917 was $5,464,493, and in 1918, $6,090,106. The total production of phosphate rock in Florida since the beginning of mining it in 1888 to the close of 1918 is estimated to be 35,210,314 tons, with a total valuation of over $129,000,000[9].

The principal uses of phosphate rock are for export as such, for the manufacture of "ground phosphate rock," and for the manufacture of acid phosphate. Smaller quantities of the rock are used in other industries, such as the manufacture of matches, and the manufacture of various chemicals—phosphoric acid, ammonium and sodium phosphates, etc.

Within recent years the use of ground phosphate rock as a fertilizer has been strongly advocated, and its use has been recommended in some quarters as a substitute for acid phosphate. The producers of phosphate rock have a direct interest in promoting the demand for the raw product, which they can afford to sell for a much lower price than acid phosphate can be sold for. On the other hand, the manufacturers of acid phosphate and of sulphuric acid are directly concerned with increasing the demand for acidulated rock. Much argument has therefore arisen, pro and con, regarding the real value of ground phosphate rock as a fertilizer. As a factor tending toward a decision of the subject in dispute, by a disinterested authority, the following extract from the Georgia Department of Agriculture is to the point:[10]

TABLE III. PHOSPHATE ROCK EXPORTED FROM THE UNITED STATES, YEAR ENDED JUNE 30, 1919

Kind of Rock	Tons	Value
Land pebble	78,027	$448,855
High-grade hard rock	80,834	715,104
All other	30,227	328,575
Total	189,088	$1,492,534

"Ground phosphate rock gives very small returns in soils deficient in organic matter, hence the poor results obtained when used on clay soils. It does much better in sandy soils containing much organic matter. Soil acids and rotting organic matter are regarded as making the phosphoric acid of the rock slowly available for plants.

"The ground rock can be mixed with compost or in the manure pile, or even sowed in the furrow with six or eight times its weight of manure, and then it will give some returns. Even on cotton lands that have very little organic matter present in their soils, the use of phosphate rock is better than the entire omission of all fertilizers. But for this crop, acid phosphate will net much richer returns even if bought at much greater prices.

"It is not to be concluded from the foregoing statements that ground raw phosphate is without any value. It most assuredly is of value on certain types of soil. But the farmer should be cautioned against indiscriminate buying at extravagant prices because of extravagant claims of agents and dealers in this material."

Acid Phosphate

The first acid phosphate to be made by the modern method of treating phosphate rock with sulphuric acid was made in England in 1841.[11] The manufacture of acid phosphate is a simple chemical process. Approximately equal parts (the precise proportions being determined by the composition of the rock and the strength of the acid) of ground phosphate rock and 52-53 deg. sulphuric acid are mixed in a cast-iron pan equipped with agitators or stirrers, and the mass is then dumped into bins or "dens." The equipment of an acidulating plant consists chiefly of rock mills, screens, mixers, acid tanks, and dens. On account of the scarcity of labor the tendency among manufacturers is to adopt modern labor-saving devices, such as traveling cranes and belts, overhead trolleys or tracks, Link-Belt or Jeffrey loaders, Thew shovels, grab buckets, etc., whereby large quantities of bulk materials may be handled quickly and cheaply.

The phosphate rock is ground so that 90-98 per cent will pass through a 60-mesh screen, a weighed quantity of the "dust" is delivered, together with an accurately weighed or measured quantity of sulphuric acid of known strength, onto a mixing pan of one or two tons capacity, a usual size being 7 ft. in diameter and 2 ft. deep. The mass is stirred by mechanical stirrers until an intimate mixture is obtained, and is then dropped into dens, where it is allowed to remain for at least 12 hr. If, after a night in the den, the acid phosphate is found to be in a reasonably dry state, it is removed from the den and placed in a large pile, where it is left for 30 days or more to "condition" (during which time the excess of moisture escapes), after which the acid phosphate, or superphosphate, is ready for shipment or to be used for making complete fertilizer.

Acid phosphate will ordinarily show on analysis the following composition:

	Per Cent
Water-soluble phosphoric acid	14
Reverted phosphoric acid	2
Insoluble phosphoric acid	1

The exports of acid phosphate, for the fiscal year ended June 30, 1919, were 51,405 tons, valued at $1,548,678. It is estimated that about 4,000,000 tons of acid phosphate were manufactured in the United States in 1917, and that in 1918 about 4,500,000 tons were manufactured, the value of the product for the latter year being estimated at $76,500,000. For the manufacture of this huge tonnage of acid phosphate, large quantities of sulphuric acid have been required. But the

[9] "Statistics on Mineral Production in Florida During 1918," by Herman Gunter, State Geologist. Press Bulletin No. 11, Oct. 6, 1919, p. 5.

[10] Bulletin No. 76, Georgia Department of Agriculture, 1918, p. 40, ff.

[11] Sellards, *op. cit.*, p. 87.

sulphuric acid industry is dependent on the mineral industry for its principal raw material, and the development of the pyrite and sulphur deposits of the South has resulted from the demand for sulphuric acid.

Sulphur

Up to the year 1918, two companies, the Union Sulphur Co., Sulphur, Calcasieu parish, La., and the Freeport Sulphur Co., near Freeport, Brazoria county, Tex., produced more than 99 per cent of the sulphur mined in the United States. A small amount of sulphur was produced in three Western states—Nevada, Wyoming and Colorado—but it is noteworthy that without the product from the Southern states named the output of brimstone from the United States was practically nil. During 1918 a third large producer—the Texas Gulf Sulphur Co., whose plant is at the mouth of the Colorado River, at Matagorda, Tex.—and again a Southern one, entered the field.

The production of brimstone in the United States for the year 1918 was reported as 1,352,283 tons.[12] The estimated production for 1917 was given as 1,137,000 tons. The tonnage for 1917 was said by the United States Geological Survey to have been nearly 50 per cent greater than in 1916, while during that year the production of brimstone was several hundred per cent greater than in any year before the war.[13]

The character of the sulphur deposits in the Southern states has been described by Philip S. Smith.[14] As is well known, these deposits are mined by the ingenious process developed by Herman Frasch. The original Frasch patent of Oct. 20, 1891, having expired and the later patents having recently been declared invalid,[15] the process, heretofore considered to be an exclusive one, appears now to be open to general use.

Besides the manufacture of sulphuric acid, the principal use of sulphur is in the manufacture of paper. Smith[16] states that paper manufacturers report a consumption of one-eighth of a ton of sulphur for each ton of sulphite pulp manufactured. According to census returns, the sulphite pulp industry in the United States consumed 136,456 short tons of sulphur in 1914.

Prior to the war, very little sulphur was used in this country for the manufacture of sulphuric acid. But owing to the combined effect of increased demand for acid for the manufacture of munitions and the diminished supply of ships for the transportation of pyrites from Spain, the quantity of sulphur used for the manufacture of sulphuric acid has very greatly increased. The producers of acid report that 463,364 long tons of domestic sulphur were used by them in 1917.[17] Obviously, most of this must have come from the South.

Pyrites

Pyrites, or pyrite, whose main use is for the manufacture of sulphuric acid, was prior to the war imported into the Southern states in large quantities from Spain. The exigencies of the war stopped most of this importation, and it was expected that the production of domestic pyrites would be greatly stimulated.

Virginia takes first rank among the states as a producer of pyrite, both as to quantity and value of output. In 1916 this state produced 148,502 long tons, valued at nearly one million dollars. Virginia's production in 1917 was 170,382 long tons. According to the Virginia State Geological Survey, the pyrite producers at present are:

The American Agricultural Chemical Corp., operating the Cabin Branch mines, Prince William county.

Grasselli Chemical Co., operating the Arminius mine, Louisa county.

Sulphur Mining & Railroad Co., operating a mine three miles north of Mineral, Louisa county.

The General Chemical Co., operating a mine at Monarat, Carroll county.

Two mines in Louisa county, one owned by the Armour Fertilizer Co. and the other by Boyd-Smith Mines, Inc., were reported not operating in 1919. The Ohio Sulphur Mining Co., operating near Proffit, Albemarle county, reported development work in progress, and the Western Pyrites Corp., operating near Garrisonville, Stafford county, reported that it expected to resume production about the first of December.

Among the Southern states, Georgia ranks second as a producer of pyrite. Georgia contributed 23,242 long tons in 1917. Besides Virginia and Georgia, the Southern states producing were Alabama, Kentucky and Tennessee.

The total production of domestic pyrites in 1917 was reported by the United States Geological Survey as 462,662 long tons, an increase of 10 per cent over the 1916 production. The expected increase in pyrites production for the year 1918 did not materialize. This failure is attributed to the difficulty in securing labor, to the war-time restrictions placed on the delivery of mining equipment and other supplies, etc. The production for 1918 was estimated at 453,637 long tons[18], about 10,000 tons less than in 1917, or a loss of about 2 per cent.

Pyrrhotite and Copper Sulphides

Pyrrhotite, while it is, like pyrite, an iron sulphide, is considered separately, as it is found associated with copper sulphides and has been treated along with the copper sulphides, primarily for the recovery of copper. The method of producing the sulphur dioxide from the sulphur, applied to these ores, is different from the method applied to pyrite. Otherwise the process of making the acid is practically the same.

The pyrrhotite deposits used for the manufacture of sulphuric acid and found associated with the sulphides of copper are mined in the Ducktown district in the southeastern corner of Tennessee, just north of the Georgia line and just west of North Carolina. These deposits have been worked for many years for their copper values, and since 1907 sulphuric acid has been made as a byproduct from the escaping fumes of the copper blast furnaces. There are two companies operating in the district—the Ducktown Sulphur, Copper & Iron Co., Ltd., and the Tennessee Copper Co.—and the total tonnage of ore mined annually by the two companies is in the neighborhood of half a million tons. The developed ore reserves at the mines of these companies is sufficient to permit the continuance of operations at the above rate for a number of years.

The process of smelting is the usual one for copper-iron sulphides, and consists of two operations: (1) smelting the ore in blast furnaces (in either one stage

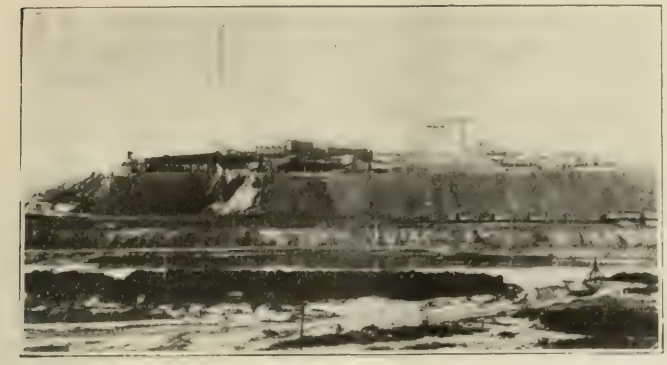

FIG. 2. GASES ESCAPING AT THE TENNESSEE COPPER CO. PLANT

or two stages) for copper matte, containing 30 to 40 per cent Cu; (2) blowing the matte to blister copper in basic lined converters. The amount of copper marketed is about 13,000,000 to 14,000,000 lb. annually.

Sulphuric Acid

According to the United States Geological Survey, the numbers of sulphuric acid plants operating in the several Southern states in 1916 were as follows:

Alabama	12	Mississippi	5
Arkansas	1	North Carolina	12
Florida	5	Oklahoma	1
Georgia	30	South Carolina	15
Louisiana	3	Tennessee	6
Maryland	11	Texas	3
		Virginia	9
Total, Southern states			113
United States (1917)			221

As fifteen plants were undistributed, the above total for the Southern states is probably slightly too low. The value of the acid produced in Virginia, Maryland and Georgia in 1917 was more than $5,000,000 for each state.

During 1917 and 1918 many new sulphuric acid plants were built in the Southern states, some of them of unusual size. A chamber plant of 600 tons daily capacity had been barely completed at Little Rock, Ark., when the armistice was signed, and had not yet been put into operation. At Brunswick, Ga., a chamber plant for the manufacture of 800 tons per day of 60 deg. Bé. acid was 40 per cent completed on Nov. 11, 1918, but work on the plant was stopped after the signing of the armistice. A large contact plant at Nashville, Tenn., was 75 per cent completed on the day of the armistice, and construction work on this plant also has been stopped.

Even before these large plants were designed, however, the South already had the largest sulphuric acid plant in the world—larger than either the Little Rock or the Brunswick plant—in the 6,500,000 cu.ft. of chamber space owned and operated by the Tennessee Copper Co., at Copperhill, Tenn. The average daily capacity of this plant is 1,000 tons (60 deg. Bé.), but the output often falls short of this amount, owing to fluctuations in the supply of gas. It has produced, for ten consecutive days, a daily average of 960 tons of 60 deg. Bé. acid, and there have been single days when over 1,100 tons of acid were reported.

FIG. 3. FUMELESS OPERATION AT THE TENNESSEE COPPER CO.

For a long time the plant operated on the waste fumes of the copper blast furnaces only. Up to this year, no practical means had been developed of utilizing the waste fumes of the copper converters, and the equivalent of fifty tons or more daily of sulphur had for a long time escaped. Recently it has been found possible to utilize the converter gas, in addition to the blast-furnace gas, without any addition whatever to the size of the acid plant. The gases from both sources (furnaces and converters) are combined in one common flue, and by means of lead fans of unusual size are drawn into the capacious chambers, and are there condensed into acid. By this means practically all the sulphur volatilized, by furnaces and converters, is recovered as acid. The sulphur recovery for the months of October and November this year was 90 per cent, based on total sulphur volatilized. Since a recovery of 95 per cent of the sulphur, for a plant built exclusively for the purpose of making sulphuric acid, is considered good practice,

FIG. 1. ARMOUR ACID PHOSPHATE PLANT

it is apparent that the sulphur loss at this huge byproduct plant is approaching an irreducible minimum. The dense white fumes, formerly seen escaping from the tall chimney, the irritating gases, which in past years had swept the furnace charging floors, a detriment to successful furnace operations and a serious handicap to the furnace tenders, are today conspicuous by their absence. The atmosphere in the vicinity of the smelter is almost entirely free from sulphurous gas, and the 325-ft. chimney, which formerly poured forth vast volumes of sulphurous gases, stands today cold and empty —a monument to the waste of the past. The accompanying photograph (Fig. 2) illustrates the effect "before," Fig. 3 shows the effect "after," instituting the recent improvements in operating methods.

Fertilizer

As the manufacture of acid phosphate is dependent on the sulphuric acid industry, so the vast fertilizer business of the United States is dependent on the acid phosphate industry. The three largest manufacturers of chemical manures are the American Agricultural Chemical Corp., the Virginia-Carolina Chemical Co., and the International Agricultural Corp. Most of the plants of these concerns are located in the Southern states, and in addition there are scattered throughout the South

many fertilizer plants owned and operated by the well-known meat packing concerns—Swift, Morris and Armour—as well as many owned by independent concerns, some large, such as the Royster Guano Co., and some smaller ones.

The manufacture of complete fertilizer consists in mixing acid phosphate in suitable proportions with nitrogenous materials, such as dried blood, tankage, fish scrap, or cottonseed meal, and potash salts. Sometimes the nitrogen or the potash is omitted, in which case the product becomes either "alkaline goods" (acid phos-

FIG. 5. MORRIS & CO. FERTILIZER PLANT

phate with potash) or "ammoniated superphosphate" (acid phosphate with nitrogenous material).

The complete fertilizer containing phosphoric acid, nitrogen, and potash, contains these ingredients in some definite proportion, such as 8 parts of the first to 2 parts of the second to 2 parts of the third—in which case the fertilizer would be known as "8-2-2" grade.

The manufacture and sale of fertilizers in the Southern states is regulated and controlled by state laws, supported by state chemists and their laboratories.

Table IV shows the amount of fertilizers consumed in the Southern states in 1918, compared with the total consumption for the United States.

TABLE IV. CONSUMPTION OF FERTILIZERS IN THE SOUTHERN STATES AND IN THE ENTIRE U. S. FOR THE FISCAL YEAR ENDED IN 1918*

States	Tons Consumed	States	Tons Consumed
Alabama	289,990	Mississippi	104,700
Arkansas	88,500	North Carolina	921,962
Florida	197,954	Oklahoma	25,000
Georgia	923,020	South Carolina	1,064,886
Kentucky	128,000	Tennessee	113,000
Louisiana	81,025	Texas	58,000
Maryland	173,000	Virginia	430,549
Total, South			4,599,586
United States			6,991,743

*Compiled from American Fertilizer Hand Book, 1919, page 20.

Figs. 4 and 5 show the Armour Co. and Morris & Co. fertilizer plants, both of Atlanta. In each case, the sulphuric acid plant can be seen at the left.

The statistics given will serve to show the magnitude of these industries of the South. There are many other Southern industries—mineral, chemical, and metallurgical—which will compare, as to capital involved and value of product, with the phosphate, sulphuric acid, and fertilizer industries, and some, perhaps, will surpass these. The coal and iron of Alabama, the coal of Kentucky and Tennessee, the marble of Tennessee and Georgia, the oil of Oklahoma and Texas, the naval stores and cottonseed oil industries, the hardwood industries of the Appalachians—a study of all these would prove profitable to those who are interested in the progress of the South.

Atlanta, Ga.

World's Sugar Crop Estimates*

The world's cane-sugar of 1918-19 is estimated to be 340,371 tons less than the production of 1917-18, according to the latest estimates of Willett and Gray. The beet-sugar production is estimated to have decreased by 642,184 tons, making a total estimated sugar shortage of 982,555 tons, as compared with 1917-18. Tables I and II give the final statistics for the years 1916-17 and 1917-18, and the estimates for 1918-19.

Importance of the Soap Bubble

R. S. Williams calls attention in the *Journal* of the Society of Chemical Industry in an article on the theory of flotation to the fact that the forces at work in a soap bubble are of such technical importance that 60,000,000 tons of ore are annually treated by their application.

**Fortnightly Information Review* of American Chamber of Commerce in France, Sept. 15, 1919, p. 273.

Some Aspects of Cheap Cyanide Processes*

Review of the Developments Made in Cyanide Synthesis—Improvements Made in the Ferrocyanide Process—Reactions Between Nitrogen, Carbon and Alkaline Bases—Fixation in the Electric Arc—Cyanamide Process

BY HERBERT PHILIPP
Consulting Chemical Engineer

THE possibilities of cyanide manufacture cover practically the whole field where cyanogen products can be or are produced, because in one way or another alkali cyanide can be formed from almost any compound containing cyanogen. This accounts for the varied processes proposed by inventors and chemical engineers.

Cyanogen products are deserving of interest; they are on the boundary between inorganic and organic chemistry, in fact, they are on both sides of the fence, which often creates some inconvenience.

An alkali cyanide (RCN) has all the properties of an inorganic salt, like an alkali halide. yet from an organic point of view it must be considered as the nitrile of formic acid, and its chemical behavior bears it out.

For instance, if a cyanide is hydrolyzed under proper conditions we get a formate:

$$NaCN + 2H_2O = NaOOCH + NH_3$$

or if hydrogen cyanide is reduced we get methylamine

$$HCN + 2H_2 = H_3CNH_2$$

The same applies to cyanogen (C_2N_2), which is the nitrile of oxalic acid, NC.CN, ethane dinitrile.

History of Cyanogen Products

Cyanogen products hold several historical records. C_2N_2, cyanogen, was isolated in a pure state by Gay-Lussac in 1815, which is the first recorded instance of the isolation of a compound radical. Another record, which I shall refer to a little later, is the fact that the first commercial process in the world for using atmospheric nitrogen to form a chemical compound was a process for the manufacture of ferrocyanides.

By the word "cyanide" in this paper I refer to an alkali cyanide, which has reference today chiefly to sodium cyanide, potassium cyanide being met with scarcely any more in the commercial world, except as a pharmaceutical and laboratory chemical.

When cyanide first became a commercial article, it was in the form of potassium cyanide, and as the art developed mixtures of sodium cyanide and potassium cyanide became the commercial article, while today sodium cyanide of high purity is universally used.

Since the user of cyanides really only wants the cyanogen ion (-CN), it is not so important whether sodium or potassium is the carrier. Since the largest users of cyanide are located long distances from points of manufacture, the more -CN a product contains the lower the freight charge on the cyanogen bought, therefore the lower the atomic equivalent weight of the carrier of the cyanogen ion the better the consumer likes it.

Thus lithium cyanide would be a very desirable product if it could be manufactured cheaply enough, and even calcium cyanide would be better than sodium cyanide. Owing, however, to the instability of calcium cyanide, it is doubtful whether it will ever have a commercial future.

Uses of Ferrocyanides and Cyanides

Originally, ferrocyanides were manufactured to make prussian blue, which was, and still is, used as a coloring matter. Alkali cyanides became important only after the McArthur and Forest researches around 1890 showed such astonishing results in the working up of low-grade gold ores. The cyanide industry obtained an impetus and vitality at that time which made it acquire rapid development, and as its production price decreased, more and more uses for cyanide have been found, so that there is every reason to believe that the demand for cyanide will still increase. Despite the fact that the flotation process in the mines has decreased the use of cyanide, the other uses of cyanide are continually increasing, so that as far as the disposition of cyanide is concerned, its use in the mines will soon be of secondary importance.

In Fumigation and Industries

Fumigation with hydrocyanic acid has developed into a large industry, and possibly the largest consumption of cyanide must be credited to this industry. A short time ago fumigation with hydrocyanic acid was done by generating the gas where the fumigation took place, but now liquid hydrocyanic acid is used direct and there are two plants in California manufacturing the acid. The greatest use of hydrocyanic acid is for an insecticide (originally for killing the San José scale) in the orange groves, and I believe today every orange coming from California has undergone a fumigation with hydrocyanic acid. Hydrocyanic acid is perhaps the best insecticide known, and can be used for fumigating plants and foods without detriment. Buildings and vessels can be fumigated with advantageous results, in fact the United States Government has already used this process on many ships. The difficulties regarding the transportation of hydrocyanic acid, which I have no doubt will be overcome, prevent this material being more extensively used.

The electroplating industry, which also includes the metal cyanides, are also important users of cyanides. The casehardening of steel, where sodium cyanide and also ferrocyanides are used, has grown extensively with the increased production of motor vehicles and other mechanical arts. Smaller uses include submarine paint, fluxing powders for brazing and welding, organic chemicals, pharmaceutical and laboratory reagents.

Consumption of Cyanides

It is very difficult to give any exact data regarding the consumption of cyanides in this country, as the

*Paper read before the New York Section, American Electrochemical Society, Jan. 23, 1920.

Government statistics generally include other chemicals, owing to the fact that for many years there has only been one producer. Therefore, the figures given here can only be considered approximately. In 1898 the consumption in the United States was about 3,000,000 lb.

The consumption was practically trebled in the next year (1899). The consumption has continually grown, about 16,000,000 lb. per year being manufactured in the United States between 1914 and 1918, according to Government statistics, while previous to the war an additional 9,000,000 lb. per year was imported. Of course during the war very little of European goods found their way here. During 1917 about 1,500,000 lb. came here from England. There appears therefore to be a market here for about 25,000,000 lb. per year.

Commercial Cyanide Processes

Originally potassium cyanide was manufactured from ferrocyanides, by just heating the same.

$$2K_4Fe(CN)_6 = 8KCN + 2FeC_2 + 4N$$

Here was a large loss of nitrogen, and a great improvement occurred when the ferrocyanide was melted up with potassium carbonate.

$$2K_4Fe(CN)_6 + 2K_2CO_3 = 10KCN + 2KCNO + 2CO_2 + 2Fe$$

Here the finished product was contaminated with cyanate, which, however, did not offer any detriment to the extraction of gold from the ore.

Over twenty-five years ago Hamilton Y. Castner produced metallic sodium comparatively cheaply and this allowed the cost of the above process to be considerably lowered. Instead of using potash for making a melt with the ferrocyanide, sodium was used, thus giving all the nitrogen as cyanide.

$$K_4Fe(CN)_6 + 2Na = 4KCN + 2NaCN + Fe$$

Sodium or potassium ferrocyanide we will always have with us as long as the gas industry lasts. In the gas industry a large number of complex cyanogen and ferrocyanogen products are collected, which are converted to ferrocyanides. There is a good market for sodium ferrocyanide today, and the price is too high to allow it to be used as a raw material for making sodium cyanide.

Castner and Pfleger's Process

Soon after this an entirely new process for the manufacture of cyanides was developed, using Castner's metallic sodium as a basis. The process was developed by Castner and Pfleger, and is important, as it is the predominant cyanide process of today.

The process is chemically very simple:

$$2Na + NH_3 + C = 2NaCN + 3H_2$$

This reaction, however, takes place in three steps.

(1) $2Na + 2NH_3 = 2NaNH_2 + H_2$

(2) $2NaNH_2 + C = Na_2CN_2 + 2H_2$

(3) $Na_2CN_2 + C = 2NaCN$

The process is very interesting and deserves the greatest consideration for anyone developing a new process. The commercial manufacture of cyanide by this method is very clean, and as the finished product is a melt and is cast direct into forms, very little handling is required and no loss by decomposition is endangered, as in the case where solutions are handled. It has none of the disadvantages or expenses encumbering a process where cyanide has to be separated from liquids.

The expensive raw materials are ammonia and metallic sodium. As regards ammonia, we all know that a synthetic process for making cheaper ammonia will soon be realized. Metallic sodium is made by the Castner process by electrolyzing caustic soda, and this process has been considerably improved in the last decade by Dr. H. R. Carveth and his assistants. There is also another sodium process in commercial operation in West Virginia, where sodium chloride is electrolyzed. This process was developed by R. J. McNitt. I especially bring these points out, because cyanide manufactured by this method is not burdened by any leaching or dissolving process, which in the case of cyanides is quite an expensive and unpleasant operation, and even with the higher cost of raw materials a synthetic process where the finished product has to be leached out must be very efficient to offset the higher priced raw materials in the present process.

The Schlempe Process

Another process which is worthy of mention is the so-called "Schlempe process." This process uses the residues from beet sugar manufacture (vinasse). This process has been in operation in Germany at the Dessauer Refinery since about 1900 and was developed to a commercial success by Bueb. Owing to the large distance separating the various beet sugar factories here, it has possibly been found impractical to install such a plant, because a small plant could easily use the residues from several beet sugar plants.

The vinasse consists chiefly of potash salts. The vinasse is distilled and the vapors contain ammonia and trimethylamine. This latter is passed over heated porcelain and decomposed at a temperature of 1,000 to 1,100 deg. C. into HCN.

$$N(CH_3)_3 = HCN + 2CH_4$$

The gases have to be moved rapidly, otherwise the hydrocyanic acid gas decomposes:

$$HCN + 3H_2 = NH_3 + CH_4$$

The hydrocyanic acid is absorbed by caustic soda solution and evaporated *in vacuo*, and at a temperature of 30 deg. C., cyanide separates out. The carbonized residue left in the distilling retort is leached to obtain potash salts.

Recovery of Alkali Cyanides From Aqueous Solutions

Just a word on the recovery of alkali cyanides from aqueous solutions. Owing to the easy decomposition of aqueous solutions containing alkali cyanide, many of the earlier processes failed.

The two following reactions are likely to take place where cyanides are in solution:

(1) $NaCN + H_2O = HCN + NaOH$

(2) $NaCN + 2H_2O = NH_3 + NaCOOH$

If cyanide solutions are contaminated with salts, other than small quantities of the hydroxide or carbonate of the alkali, recovery by crystallization is very difficult and generally impossible. Therefore it has frequently to be converted into ferrocyanide and crystallized.

When a solution is obtained by saturating a pure caustic solution with hydrocyanic acid, a little excess of caustic should always be allowed to remain. Such a solution can be evaporated *in vacuo* and cooled, when crystals of cyanide ($NaCN, 2H_2O$) will appear. These crystals are centrifuged and dried *in vacuo*, when a white loose powder of anhydrous cyanide will remain. The powder can be compressed into briquets at a pressure of about three tons to the sq.in. These treatments

require that the cyanide has to pass through several costly steps, and the longer the cyanide is in solution the greater the loss by decomposition.

New and Proposed Processes

We now come to a discussion of some of the possible new fields for the development of future cyanide processes. The future development in this direction will use atmospheric nitrogen as the basic raw material, and the processes can be divided into two main groups, namely, direct synthetic formation of cyanides and the indirect formation of cyanides.

The first group (I) is divided again into two subdivisions, (*a*) cyanides from nitrogen, alkali, and carbon, and (*b*) fixation of hydrogen, carbon (or hydrocarbons) and nitrogen in the electric arc or at high temperatures.

The second main group (II) consists of making cyanides indirectly from carbides, nitrides and combinations of these compounds.

Cyanides From Nitrogen, Alkali and Carbon

The formation of alkali cyanide by passing atmospheric nitrogen over heated alkali carbonate and carbon is very old.

Already in 1839 Lewis Thompson spoke before the British Society of Arts on making prussian blue by passing atmospheric nitrogen over carbon and potash under favorable conditions, and in 1843 Possoy and Boissierre (Br. Pat. 9,985) erected a factory near Paris to make potassium ferrocyanide by passing atmospheric nitrogen over strongly heated charcoal saturated with potassium carbonate. Owing to the excessive fuel requirements the process was moved after one year to Bramwell & Co.'s works at Newcastle, England, who were manufacturers of prussian blue. Several improvements were introduced, and cheaper fuel obtained. Iron ore was added to the charge in the retorts, and the process was in operation for two years and is reported to have manufactured one ton potassium ferrocyanide per day. The process was not a commercial success and was abandoned on account of the large amount of fuel used and the short life of the retorts.

The Possoy and Boissierre process is of great historical interest, as it is the first commercial process on record where atmospheric nitrogen was used as a raw material and entered into the reaction, and the value of iron as a catalytic agent was recognized even before the publication of Bunsen and Playfair's investigations (*Brit. Assoc. Report*, 1845, p. 185) on the formation of potassium cyanide in the blast furnace.

Many Experiments With Small Variations

Since that time a host of experimenters have taken up this subject and with small variations have endeavored to find a process for making cyanide by an inexpensive process.

In 1862 Marguerite and Sourdeval replaced the potash with barium hydrate and carbonate, which appeared to be a great step forward, as barium products, especially barium carbide, have great affinity for nitrogen and further, the barium oxide and carbonate do not fuse as easily as the corresponding alkali compounds. The nitrogen was exceedingly well absorbed, but no cyanide was manufactured, only ammonia, as steam was passed over the mass at 300 deg. C. Mond (U. S. Pat. 269,309), in 1892, tried to improve this process by mixing calcium carbonate, magnesium carbonate, strontium carbonate to the mass, with the idea of increasing the ammonia yield.

V. Adler's patents (Ger. Pat. 12,351 *et al.*), 1881-1885, are worthy of mention and show that he did quite a lot of work to accomplish commercial results, and if the engineering art had been as far advanced then as it is today he would have possibly achieved far better results.

However, many attempts have been made and much money has been spent on these efforts to manufacture cyanides from the nitrogen of the air by these methods, and a large number of patents exist for more or less improvements, but in spite of all efforts none of these methods has become commercially successful.

Even today similar processes are being developed, but as far as I know no product by these processes is yet on the market.

The Bucher Process

This method of forming cyanides has been very thoroughly brought out recently by John A. Bucher (*Amer. Inst. Chem Eng.*, 1916, p. 335). The work of Prof. Bucher has been widely quoted and his laboratory work is very creditable to him. The Bucher process is very similar in principle to the older processes and recognizes that large quantities of iron must be present to obtain satisfactory results. This process was recognized at the beginning of the war by our Government as worthy of development, and a plant was erected at Saltville, Va., to manufacture cyanide by this method. Although the plant was not put in operation during the war, the Government officials reported that the process could be considered commercially successful. However, as far as I know no material by this process has reached the market. Very similar work is being undertaken by the Air Reduction Co.

The reaction taking place is as follows:

$$Na_2CO_3 + 4C + N_2 = 2NaCN + 3CO - 138{,}500 \text{ cal.}$$

The advantage of such a process compared with the present one is the use of cheap raw materials. The most important steps in the manufacturing process are the fine grinding of iron and charcoal, impregnating the mass with sodium carbonate, making it up into uniform size pieces and very thoroughly drying the formed mass. These pieces are then introduced into a retort externally heated, and reacted on with atmospheric nitrogen at temperatures below 1,080 deg., as above that temperature the formed cyanide decomposes in the presence of iron.

$$2NaCN + Fe \text{ above } 1{,}080 \text{ deg. C.} \rightarrow FeC_2 + 2Na + N$$

The cyanided mass in the retort must be either allowed to cool in an atmosphere of nitrogen in the retort or else taken out of the same without allowing the heated mass to come in contact with the air, as in the latter case decomposition takes place by the burning of the cyanide and the formation of iron cyanogen compounds, which would necessitate converting the cyanide products formed into ferrocyanide. When the mass is cold the soluble cyanide and unconverted carbonate is lixiviated with water, great care being used to prevent formation of ferrocyanide. It is advisable to have a slight amount of unconverted sodium carbonate present, as this helps prevent the formation of ferrocyanide.

The further steps represent the separation of the sodium cyanide from the aqueous solution, which I have already described. Efforts have been made to use organic solvents to extract the cyanide instead of

water, which would be very desirable, but this adds to the expense.

The disadvantages offered by this process are the number of steps involved, the short life of the retorts, the inability to use the finely divided iron many times, owing to the accumulation of impurities, and the separating the sodium cyanide from aqueous solution. It will therefore be seen that the expense incurred to overcome the many disadvantages considerably offsets the advantage of using cheap raw materials. In connection with lixiviation it is practically impossible to dissolve out all the sodium cyanide from the mass, and 0.5 to 1 per cent cyanide remains undissolved. This could of course be extracted, but the time involved and the extreme diluteness of the solution obtained makes such a step uneconomical.

The R. & H. Developments

In 1894 H. Y. Castner (U. S. Pat. 239,643) described a process for the formation of sodium cyanide by passing a current of nitrogen over heated charcoal upon which the alkali metal flows. As far as I have been able to ascertain he did not conduct any experiments in this direction, expecting later to undertake the investigation which his early death prevented him from carrying out. However, during the last decade considerable work in this direction has been carried on by the Roessler & Hasslacher Chemical Co. By the direct combination of the elements sodium, charcoal and nitrogen, sodium cyanide is formed. This reaction is exothermic and on a small laboratory scale gives very efficient results.

In developing this process to a commercial scale a large number of difficulties have had to be dealt with. In this process a simple end product is desired, as in the present process where ammonia is used instead of atmospheric nitrogen, that is, the finished furnace product must be a pure melt of sodium cyanide.

The desired reaction is as follows:

$$2Na + 2C + N_2 = 2NaCN + 46{,}200 \text{ cal.}$$

If nitrogen gas and sodium vapor are passed over heated charcoal, sodium cyanide is easily formed. Even at temperatures as low as 650 deg. C., the cyanide is formed. With a rise in temperature the reaction is speeded, and if temperatures over 1,080 deg. are obtained no iron retort must be used, as otherwise the iron will decompose the formed cyanide and the retort will gradually go to pieces. Of course catalytic substances, like iron, will help speed the reaction at lower temperatures, but in that case the cyanide would have to be lixiviated, which disadvantage would easily offset any advantages over the present process, where ammonia is used.

The great difficulty experienced is not in obtaining a suitable material for a retort, but in separating the formed sodium cyanide from the charcoal. Although sodium cyanide melts below 600 deg. C., it is held fast by the charcoal, in which it is absorbed, and surrounds the particles of charcoal so that sodium vapor and nitrogen cannot come in contact with it. Of course a large amount of formed cyanide will drip off the charcoal mass, but a cyanided mass will by degrees fill the retort.

The alternative of this difficulty is to distill off the formed cyanide, which is feasible, as there are no other substances present which could distill over. In the case where sodium carbonate or chloride is present it is not easy to distill the cyanide, as both these salts are more volatile than sodium cyanide. Sodium cyanide can be heated to a high temperature without decomposing. Temperatures of 1,250 to 1,300 deg. C., about which temperatures sodium cyanide distills, do not decompose it. Sodium cyanide can be volatilized at a much lower temperature in a current of nitrogen gas.

The process consists of feeding finely divided charcoal into a retort or electric furnace, which must be heated initially to start the reaction. This reaction, being exothermic, can be self-sustaining. Sodium vapor can be produced inside of the furnace or else conducted from the outside into the carbon mass. The nitrogen of course must be led from the outside. The finished product, which is distilled off, can be melted again and cast into forms or can be used as taken from the condensers.

The advantages such a process would show are an exothermic reaction, continuous operation of furnace, little or no expense on finished furnace product, and few steps in the operation.

The disadvantages are the high cost of one of the raw materials, namely, metallic sodium. I do not think sodium cyanide from such a process is regularly reaching the market, although quite a quantity in the past has been produced. The process is not yet far enough advanced to be considered a commercial success.

Fixation in the Electric Arc

The commercial development of making hydrocyanic acid gas at high temperature was started only shortly before the war, although laboratory experiments date back to the latter part of last century.

The electric-arc furnaces have for their object the synthesizing of hydrogen and carbon (or a hydrocarbon) with atmospheric nitrogen. Much of the experience gained by the work done to combine the nitrogen and oxygen in the arc has considerably helped the development of such processes, although as early as 1879 James Dewar showed that gaseous mixtures containing nitrogen and hydrogen passed over heated carbon formed hydrocyanic acid.

Whether hydrocyanic acid or cyanogen is formed synthetically is not of such great moment, as they can both be converted into cyanides by absorbing them over or through a fused alkali or solution of alkali hydrate, although hydrocyanic acid is the most desired product. Dewar considered the temperature of the electric arc was necessary to combine these elements; Smith and Hutton of the University of Manchester showed by laboratory experiments that hydrogen and nitrogen in contact with carbon at temperatures above 1,800 deg. C. produced hydrocyanic acid to a very marked extent, the formation of hydrocyanic acid increasing rapidly with the increase of temperature.

The Lipinski Process

The work of A. V. Lipinski (*Z. Elektrochem.*, vol. 17, p. 761) is certainly deserving of interest. He investigated the formation of hydrocyanic acid by reacting methane and nitrogen in the high potential arc, and just previous to the war this process was developed to a commercial scale at Neuhausen, Switzerland. The process was in 1914 declared to be working well, and the trouble which had been originally experienced by carbon depositing on the electrodes was reported to have been overcome. It is reported that the methane was completely converted into hydrocyanic acid according to the following equation:

$$2CH_4 + N_2 = 2HCN + 3H_2$$

The use of hydrocarbon of course overcomes the use of hydrogen as a raw material. However, Lipinski obtained the best results by using a mixture consisting of 13 to 24 per cent nitrogen, 5 to 10 per cent methane, 66 to 81 per cent hydrogen. It was reported that 30 g. HCN per kw.-hr. were obtained.

To overcome the use of hydrogen as a raw material experiments were conducted to use richer hydrocarbons, which of course would increase the possibility of carbon deposits on the electrodes and other parts of the apparatus. This is one of the great objections in all high-temperature processes where hydrocarbons are used. The carbon deposited at high temperatures is extremely dense and seems to be of a graphitic nature, and it packs so hard that it is often extremely difficult to remove. This is corroborated by looking over the patent literature, where one will note the suggestions made to obviate carbon deposits. Whether Lipinski's process has continued to prove commercially successful I am unable to say, as no news regarding it has reached this country during the last four or five years.

The use of catalyzers and contact substances to reduce the reaction temperature has also received considerable attention; in fact, Lipinski used metallic vapors in his arc and also vapors of salts, like calcium chloride. P. A. Starke (U. S. Pat. 1,306,862) considerably lowers the temperature of synthetically combining hydrogen, nitrogen and hydrocarbon by passing the same over catalytic masses containing iron, nickel and cobalt, together with an earth alkali oxide, but offers no figures as to results obtained. His work is possibly still in an experimental stage and no doubt considerable difficulties have to be overcome to make such a process commercial. Starke uses no arc, but claims temperatures between 800 and 1,000 deg. C.

It is very probable that quite a lot of work has been done with arc furnaces for making cyanides and hydrocyanic acid of which little has been published. This field offers certainly a possible solution for the formation of cheaper cyanides.

If results of 30 g. HCN can be obtained per kw.-hr., such a process would prove very valuable for making cheap cyanides. Even with power at $20 or over per kw.-yr., a large margin is left for the working up of the cyanide solutions. Experiments in working out such developments are possibly no more expensive than the cost of developing some of the processes now being experimented with, and this field holds out one of the hopeful ways to the future production of cheap cyanides.

Cyanides From Carbides, Nitrides and Combinations of These Compounds

In making cyanide indirectly from other products containing combined nitrogen, fixed from atmospheric nitrogen, work has chiefly concentrated on converting the atmosperic nitrogen, combined to calcium carbide, in calcium cyanamide into sodium cyanide.

The manufacture of cheap cyanide from cyanamide is now an accomplished thing and has been developed in this country. As soon as the impetus was given to the cyanide industry, Frank and Caro in 1895 studied the possibility of absorbing nitrogen by passing the same over heated carbide. The affinity of barium compounds for nitrogen had already been recognized, and this perhaps explains why the experiments were started with barium carbide. Nitrogen gas is absorbed easily by barium carbide at comparatively low temperatures, but the resulting product consists of a mixture of barium cyanide and barium cyanamide, $Ba(CN)_2 + BaCN_2$, this material, according to G. Erlwein (1903, Fifth Inter. Cong. of Appl. Chem., vol. 1, p. 646) if used with sodium carbonate and carbon converts all the nitrogen into cyanide. By this method sixth-sevenths of the nitrogen absorbed could be recovered as sodium cyanide. The idea was to convert the barium residues again into carbide and use it over and over again, but owing to the impurities remaining in the carbide and continually increasing, the reaction product had to be discarded after a few operations. This method proved too costly and the process was abandoned. The experiments were continued, using calcium carbide as the reaction material, and in this case no cyanide was formed, the product being calcium cyanamide, $CaCN_2$. Erlwein and Frank tried to convert this material into cyanide by fusing it with sodium chloride, but only traces of cyanide were formed.

The following reaction is supposed to take place by fusing calcium cyanamide with sodium chloride:

$$CaCN_2 + 2NaCl \rightleftharpoons CaCl_2 + Na_2CN_2$$

As commercial calcium cyanamide already contains carbon, it was expected that the following reaction would take place:

$$Na_2CN_2 + C = 2NaCN$$

but this reaction did not take place and no results were obtained. It was then suggested by Freudenberg of Frankfort to use the calcium cyanamide material in the fertilizing industry.

Commercial Process Developed by Dr. Landis and His Staff

P. Kruger (Ger. Pat. 246,064) stated in 1910 that charcoal must be added to the calcium cyanamide-sodium chloride fusion to convert the cyanamide nitrogen into cyanide. It remained, however, for Dr. Landis and his staff to develop a commercial process in this direction.[1] It is true the product is only a low per cent sodium cyanide-containing mass (35 per cent NaCN), yet it is finding extensive use. It is very probable that experiments are being conducted to obtain a higher percentage product. It will not be an easy matter to distill off the cyanide, as the other salts present in the mass would volatilize with the sodium cyanide.

The advantages of such a process are cheap raw materials, and the disadvantages are the large number of steps in the process, the fact that the furnace must operate intermittently and the low per cent product obtained.

Another field open for investigation lies in the formation of certain metallic nitrides or carbonitrides. It is well known that several elements, like titanium, magnesium, aluminum, etc., form combinations with nitrogen and carbon. It appears that small experiments along these lines have been conducted; but nothing of any definiteness has yet been published which offers anything that could be construed as conducive to allow immediate hope for any development here to produce cheap cyanides. The field is still wide open and a lot of scientific investigation must preface such work, to study conditions of formation of nitrides and carbonitrides, their properties and possibilities of converting the combined nitrogen into a cyanide-containing material.

Tests on Small Engines at High Back Pressures

By Alan E. Flowers, R. J. Pepper and Crosby Field

CALCULATIONS based on theoretical considerations covering a wide range of probable operating conditions such as it would be necessary to make in an attempt to get full rated output when employing high back pressures are given by one of the authors in Chemical & Metallurgical Engineering, Jan. 1, 1919, page 18, vol. 20. Results of tests on small steam-driven compressors operating under conditions different from those given therein, and yet which are frequently found in chemical plants, indicate that the curves may be applied as an approximate method of calculation to these conditions. The increase in steam consumption with an increase in back pressure from

atmospheric to 40-lb. gage in five widely different types of machines varied from 33 per cent to 58 per cent, with an average of 49 per cent. The governors operated on the throttling principle with cut-off constant, but all varied in design, and the quality of the steam varied, whereas the curves in former articles were based on either boiler steam pressure adjustment or variable cut-off and saturated steam. Nevertheless the figure for the increase in steam consumption on the curve most nearly applicable to these conditions was 50 per cent, which compares favorably with the 49 per cent average value found. The actual results found are given in the curves herewith.

The units varied from 12.3 to 80.5 indicated hp. per 100 r.p.m. at full load, the average inlet steam pressure was 120-lb. gage, the average quality of the live steam was 99.2 per cent, while that of the exhaust steam was between 87 and 90 per cent.

FIG. 4. EFFECT OF BACK PRESSURE ON TOTAL STEAM CONSUMPTION AT CONSTANT NO LOAD

The equipment tested consisted of steam-driven air and ammonia compressors of several different makes and ratings. These units were operated exactly as they had been in normal plant operation except that the exhaust pressure was regulated and held constant at the three chosen values of 5, 20 and 40-lb. gage and the load held constant. Normal power plant units operate in actual service at 40-lb. gage back pressure, and these units have been successfully giving the service demanded of them during several years of operation. Air compressor units are equipped with fly ball type throttling governors, the output remaining fixed. One unit had its governor equipped to be controlled by the pressure of air in the compressed air system.

During the tests the air pressure was controlled by a valve manipulated by an observer stationed at a gage on the compressed air system.

During normal operation, the back pressure was governed by the demand for steam in the 40-lb. steam pressure system, additional steam being supplied when needed for the chemical processes either through an automatically operated reducing valve admitting live steam at 125-lb. pressure to the 40-lb. system or by manually operated valves. On the other hand, when the power demands were such that the exhaust steam of the power units was in excess of the immediate demands of the chemical processes, the plant operator discharged the excess into a hot well, where its heat energy was conserved in warming water. Any desired degree of closeness of control can be obtained by these means.

No heat reservoir was used in connection with this 40-lb. steam system other than that afforded by the volume of the pipe mains. Reservoirs filled with hot water at the temperature of average steam pressure have been used in connection with low-pressure exhaust steam-driven turbo units, and the use of some such

reservoirs should be given serious consideration in any future installation. It should also be noted that moist steam, where the moisture is scattered throughout the distribution system, must act in a similar way in providing heat storage and consequent re-evaporation when needed even more effectively than a tank, because of the greater amount of evaporating surface available, provided the condensate be not completely removed from the system as fast as formed, but remains to some extent along the bottom of the steam mains or, still better, distributed in fine particles through the body of the steam.

The Mayer ammonia compressor was equipped and

regularly operated with a fly ball governor acting through Corliss valve gear actuating an adjustable cut-off. This is the only unit tested equipped with a variable cut-off governor. During the test this unit was controlled in the same manner as the rest by throttling the steam. (One full load run on the Mayer ammonia compressor unit was made with the adjustable cut-off governor in action, resulting in a steam consumption about one-half that obtained with the throttle control.)

The general dimensions and data of the units tested are as follows:

Name of Unit	Steam Cylinder Diameter, Inches	Air Cylinder Diameter, Inches	Stroke, Inches	Piston Rod Diam., Inches	Steam Pipe Diam., Inches	I. hp. per 100 r.p.m.	Air Cyl. Displacement in Cu.ft. per 100 r.p.m.

* Duplex.

Operating speeds were usually from about 100 to 150 r.p.m. for the air compressors and about 35 r.p.m. for the Mayer ammonia compressor.

Steam was obtained from boilers that were supplying the entire plant, and the pressure varied somewhat during the tests, the amount of variation being determined by the usual works operating conditions. The average of the values for the steam pressure was used in working up the test results. It should be borne in mind that the load and exhaust steam pressures were closely observed and held constant, so that necessarily the same weight of steam was taken into the steam cylinder at each stroke regardless of the slightly variable boiler pressure. The only effect of a change in boiler pressure would be a corresponding change of speed. The test results have, therefore, been reduced to a common constant speed and may be truly said to represent the steam consumption for the pressures recorded. This conclusion with regard to steam consumption derived from theoretical considerations, as stated above, has also been checked and confirmed by plotting a number of the individual test values obtained at different boiler pressures and corresponding speeds. All the test results are based upon the carefully checked weights of condensed steam. The scale accuracy was checked with standard weights before the tests were begun. The weight readings were checked throughout the course of each run by keeping the scale beam floating constantly and recording the values at each 6-min. interval and comparing these with the total.

A totalizing revolution counter was used and readings were taken in three different ways. First, the speed was noted for 1 min. following each 6-min. interval, i. e., the difference between totalizing counter reading at beginning and end of each seventh minute. Second, the difference in totalizing counter readings at the beginning and end of each 6-min. interval was obtained. Lastly the total revolutions during the test were obtained as difference between readings at start and finish. The readings for 1-min. intervals were used only for check and the values used in working up the test results were the average obtained from the total reading for each run.

Before the beginning of the test, the condenser was tested for tightness of joints, and for leakage with 40-lb. pressure. Indicator cards were taken at each 6-min. interval and the indicated horsepower calculated from cards.

Surface Versus Bunsen Combustion in Gas-Fired Furnaces

IN AN address made recently to the Gas Engineering section of the Western Society of Engineers at Chicago, Prof. O. L. Kowalke, of Wisconsin University, outlined some experiments he had made in co-operation with the members of the Wisconsin Gas Association to determine the relative efficiency of the ordinary bunsen combustion as practiced in most gas-fired furnaces and the so-called surface combustion.

The problem was to determine what temperature could be attained using the gas-air mixture in each type of furnace and the relative ease with which given temperatures might be maintained. It was also desirable to discover how much oxidation would occur on the metal in the furnace when the atmosphere was either oxidizing or reducing, and the extent of structural change in the metal when heated to fairly high temperatures in strong reducing atmosphere.

Experiments were conducted in an American Gas Furnace Co. No. 5 gas furnace, 15 in. wide, 12 in. high and 18 in. long with ¾-in. gas inlet and 1-in. air inlet pipes. The muffle was removed to simulate conditions found in an ordinary heat-treating furnace. Quartz to pass ½-in. mesh was laid on the floor of the furnace with an angle of slope of 35 deg. A carborundum brick was introduced to serve as an object at which to look with the optical pyrometer.

Various mixers of gas and air were tried, the regular American Gas Furnace mixer, and the McKee mixer being principally employed. Great care is exercised by the manufacturers in constructing these mixers.

The gas was used at a 4- to 6-in. water column pressure and the air at about 5 in. of mercury, or say 2½ lb. A small blower produced the air pressure, while the gas was supplied from the commercial mains. This latter was carbureted water gas with an average B.t.u. of 600, and metered separately to the furnace.

Temperatures Reached

The furnace operating for 3 hr. without quartz bed and with unregulated supply of gas and air reached a maximum temperature of 1,420 deg. C. During this time 990 cu.ft. of gas was consumed. With the bunsen combustion, i.e., where the blast of air aspirates in the supply of gas driving the mixture to mouth of the burner, it was also hard to get high temperature in a short time.

The quartz was introduced to give surface combustion and the air was carefully regulated with an American mixer to give an excess of oxygen of about 0.1 per cent on the average and no carbon monoxide. With a gas consumption of 745 cu.ft. in 2 hr. and 36 min. a temperature of 1,420 deg. C. was obtained.

The McKee mixer was then tested, using bunsen combustion and removing quartz. The air supply was regulated to no CO and about 0.1 per cent oxygen in excess. In 1 hr. and 6 min. with 975 cu.ft. of gas the maximum temperature of 1,591 deg. C. was attained. The fireclay lining began to melt at this temperature and the furnace was shut down.

In the next test the quartz was placed in the furnace, and still using the McKee mixer, in 1 hr. 56 min. the temperature reached 1,700 deg. C. The quartz in front of the orifices melted down. One thousand cu.ft. of gas was consumed.

These experiments seemed to demonstrate that the intimacy of mixtures of air and gas, with a careful regulation of the air supply, is a factor of great importance, and it is a question which may be debated as to whether it is not fully as important as the impingement of the gas on an incandescent surface. In support of this an experiment made several years ago with producer gas giving about 145 B.t.u. per cu.ft. with a certain mixing device produced a temperature of 1,425 deg. C.

Maintaining Temperature

A series of experiments was made in which the temperature was raised to about 900 deg. C. so that an optical pyrometer of the disappearing filament type could be used. This insured certainty of calibration of pyrometer remaining constant.

With the ordinary bunsen combustion and old style mixer a temperature from 985 to 995 deg. C. consumed 125 cu.ft. of gas in 1 hr.

The same mixer and furnace, but with the quartz introduced to give surface combustion, maintained a temperature of 988 to 994 deg. C. for 1 hr., with a gas consumption of 109 cu.ft., or a saving of 16 cu.ft. over the former method.

The test with the McKee mixer, venturi type, used 105 cu.ft. of gas per hr. in maintaining the furnace at a temperature of 883 deg. C.

Oxidation of Metal

Specimens of 0.95 per cent carbon steel, ½ in. diameter, 2 in. long, with flat spots for making measurements, were left in furnace for various periods of time, removed, quenched in water, oxide film just removed and calipered.

In from 5 to 15 min. heat with a 19 per cent carbon monoxide mixture the diameter reduction was 0.0003 in. With a 1 per cent carbon monoxide mixture the loss was about the same. With 0.4 per cent oxygen the loss was slightly increased, and with 1.3 per cent of oxygen the loss in diameter was doubled.

It was found that in a 4 per cent atmosphere of carbon monoxide, acting on 0.95 carbon steel over a period of an hour and a half the specimen was severely decarbonized and the product was practically soft iron.

Woodine

"Woodine" is the new name for wood alcohol which has been suggested by manufacturing chemists in communications to the Commissioner of Internal Revenue. The Commissioner is drafting a bill to govern the manufacture and sale and to safeguard the use of wood alcohol. The chemists suggest that the presence of the word alcohol in the name carries with it the suggestion that it can be substituted for ethyl alcohol. It is also suggested that all wood alcohol be required to carry a label on which appears the words "A poisonous compound."

Secret of German Success in Chemical Works

In a report lately made in Glasgow by D. A. Bost on a visit to the Rhineland chemical works, he attributes the success of German chemical industries to cheap raw materials, cheap power, cheap carriage, discipline among process workers, the business capacity of the chemists, co-operation of chemists and engineers, and the willingness of the manufacturer to spend money because he had faith in the ultimate results.

Legal Notes

By Wellington Gustin

Liability of Stockholders—License to Make and Sell Patented Article Construed

A CASE involving some interesting points of law was recently decided in the Court of Appeals of New York. Here the defendant was sued as a holder of capital stock, not fully paid, by a creditor of the Tear Off Bottle Seal Co., under section 56 of the Stock Corporation Law of New York, which provides as follows:

"Every holder of capital stock not fully paid, in any stock corporation, shall be personally liable to its creditors, to an amount equal to the amount unpaid on the stock held by him, for debts of the corporation contracted while such stock was held by him." (Bottlers' Seal Co. vs. Rainey, 122 N. E., 200.)

It was alleged in the complaint that the debt of the corporation which plaintiff is seeking to enforce arose from the following facts. In December, 1909, the plaintiff granted to one Horner the sole right and license to manufacture, use and sell certain patented bottle caps for a period extending from date of the agreement to July 1, 1913, and in consideration for the granting of such license and patent rights, Horner agreed to pay plaintiff a license fee or royalty on all bottle caps and seals sold, further agreeing to pay and guaranteeing specified minimum sums each year should the aggregate royalties fall below these sums.

After making this agreement and on or about Dec. 29, 1909, Horner, with the consent of plaintiff, transferred all his interest in the agreement to the Tear Off Bottle Seal Co., which assumed and agreed to perform all its terms as agreed by Horner. It failed to perform, however, by failing to pay the amounts agreed upon when they became due. The defendant in this suit became a holder of stock not fully paid on Jan. 10, 1910. His contention is that the debt was contracted on Dec. 28, 1909, when the assignment was made. The plaintiff contended that upon the assignment of the agreement a contingent liability was incurred which ripened into a debt only as bottle caps and seals were manufactured, sold, and the payments fell due.

When Stockholders Must Pay

Said the court, the proper definition of the term "debt contracted," under the statute above quoted, is to be sought in the legislative intent to enforce the obligation to pay for stock which is assumed by one who becomes a stockholder. Under such statutes courts generally hold that a sum payable upon a contingency is not presently a debt and does not become a debt until the contingency has happened. Such decisions have had the result of relieving from liability those who were directors when the agreement creating the liability was signed, because it is said their cases were not fairly within the language of the statute. The same rule of construction must be applied to impress liability as is applied to avoid it.

The court held that the agreement transferred no more than a mere license, giving the right to make, use and sell the patented article for a period less than the full term of the patent. Properly speaking, the transaction was not an assignment of patent. The payments to be made under the contract were for the right to manufacture and sell free from interference for in-

fringement of patent. An agreement to pay such royalties is contingent and creates no debt until the time stipulated for payment arrives, said the court. Because in the meantime before the obligation to pay matures, the rights of the licensee may be lost by the interference of the licensor, or by assertion of a paramount right by a third party, or the license may be abandoned or assigned, with the consent of the licensor, or under conditions terminating the obligation to pay royalties.

When Duty to Pay Royalty Ceases

Nevertheless, as to the minimum payments, as fixed in the license agreement, it was urged the full liability of the corporation was fixed when the assignment was made and that as to such amounts the debt was then contracted. But, said the court, the promise to make such payments is not absolute. In legal contemplation, the enjoyment of the undisturbed use of the patent, not the mere execution of the grant of patent right, is the consideration for the royalties. The debt is not "contracted" until the consideration is furnished. If the right to make, use and sell the patent terminates meanwhile, if the licensor does not respect the right, if it had no right to transfer, then the duty to pay royalties ceases, the time for payment never arrives, and the debt is not contracted.

The debt is not "contracted" until it becomes a fixed liability, absolutely owing, established under the terms of the contract. Citing analogous cases for the rule of law, the court said that when a lease is signed, calling for fixed payment of rent, no debt is contracted until the premises are used or the rent becomes due. Hence the judgment against the stockholder was reversed.

Judgment to Deliver in Writing Unwritten Secret Formulas Is Impossible of Enforcement

From California comes a case dealing with the sale of secret formulas and showing why it is impossible to compel a seller to perform his agreement to deliver his secret formulas in writing. The Supreme Court of that state lays down the correct rules in transactions of this kind (Berry vs. Moulie, 179 Pac., 686).

It appears from the facts that plaintiff and defendant entered into an agreement by which the plaintiff was to purchase from the defendant his business as a manufacturing chemist and his secret formulas for manufacturing his products. This contract was partly carried out, and the business was moved from Florida to California and there established. A year later, difficulties having arisen between the parties, they entered into the contract dated June 30, 1915, which was the basis of this action, for the purpose of settling such differences. This latter contract plaintiff sought to have enforced by a decree of specific performance. Upon trial, findings and judgment were entered in favor of the plaintiff. However, later, this judgment was changed by the court after changing its conclusions of law, upon motion of the defendant. From the new judgment plaintiff appealed.

Courts Will Not Order a Performance It Cannot Enforce

On the appeal the court went into the merits of the contract to show why it would be impossible to enforce a specific performance of such contract. Now it must be understood the courts will not order a performance which it cannot enforce. By this contract the defendant transferred all the property described in the first agreement, dated June 17, 1914, and agreed in addition thereto, upon payment of a certain sum of money, "to immediately deliver possession of all and singular the formulas, recipes, and prescriptions in writing for the manufacture" of the products referred to in said contract of June 17, 1914, and the party of the second part (the plaintiff) thereupon agreed to assume the control, ownership, and management thereof, and to carry on and conduct the business, and to employ the party of the first part (the defendant) as manufacturer of the products on a certain specified salary, such employment to continue until the payments provided to be made by the second party were fully paid.

Plaintiff further agreed that he would use every effort to make the business profitable and successful, and that he would carry the trade marks and name of the seller on all the products, and that in the event that the business be sold one of the conditions of such sale should be the perpetuation, in the business so sold, of the original firm name and every trade mark adopted by it.

Findings of the Court

The court found as a fact "that defendant did not on the 30th day of June, 1915, have, nor has he since had, any written formulas, recipes, or directions for the manufacture of the products mentioned in the written agreement, but that defendant is able to reduce the same to writing, but he would, in order to reduce same to writing, be required to perform personal services and exercise his individual skill for a period of three weeks." The court also found that plaintiff was willing to employ the defendant, but that the defendant refused to perform any service whatsoever for the plaintiff.

Said the Supreme Court, the difficulty of enforcing such a contract specifically is well illustrated by the first judgment entered in the case, wherein it was decreed that the defendant should "write out or cause to be written out and authenticated when so written out" the formulas and recipes referred to in the contract and deliver the same to the plaintiff within 30 days. It was provided that upon writing out such formulas defendant was to receive $1,622, but in the event that he did not do so the plaintiff should be released from this payment. The defendant was also enjoined from engaging in the business of manufacturing such products within the State of California for the period of five years.

Agreement Not Sufficiently Certain

That portion of the decree which sought to compel the defendant to deliver or write out secret formulas is impossible of enforcement, said the court. The agreement to deliver such formulas was "an agreement, the terms of which are not sufficiently certain to make the precise act which is to be done clearly ascertainable." The contract itself was uncertain as to the secret formulas, and apparently the evidence was equally so. The secrets remained within the breast of the defendant, and he alone would know whether or not he had complied with the judgment which required him to deliver the formulas. Again the agreement specifically provided for the employment of the defendant. This agreement "to employ another in personal service" could not be specifically enforced by the defendant. That being true, said the court, there was no such mutuality of remedy between the parties as would permit specific performance.

The Personal Element in a Safety Program for the Foundry*

By M. F. Gartland

WE STATE a fact and we don't need to prove it when we say that the foundry can never be made as safe as a parlor. We may have the most expensive and most modern machinery and equipment that money can buy, our buildings may be models of perfection so far as light and ventilation and general arrangement are concerned, we may coerce our men in the matter of wearing molders' shoes, leggings, and goggles, but the fact remains that a splash of hot iron will still cause a burn when it comes into contact with the human body. A casting or a piece of pig iron will still mash a foot or break a toe if it drops at the right spot at the right time.

Our high-grade equipment will do a great deal to eliminate the splashes and other accidents due to machinery, but beyond that there is yet another element. Improved methods of handling the product will eliminate a great deal of the danger that arises from this source, but no piece of machinery or equipment has ever been made that is entirely fool-proof. We must seek yet further for the final analysis of our safety problem. We shall still have our accidents in spite of all these good things.

Elements of Danger in a Foundry

If we could operate a foundry by machinery from the pig iron yard to the shipping platform without the touch of a human hand, we should have no foundry accidents. But we can't do that; we must have men. Our foundries must be alive with men through every part of every working day. Again, if we had the men of our foundries engaged in the task of making mud pies by hand, we should have no foundry accidents. The element of danger that lies in the nature of our product would be eliminated. But we are not in the mud pie business and we are not making and shipping castings by machinery. We are making our product from pig iron and scrap. To put it on the market we must have men. Men must unload the iron, the coal, and the sand. Men must charge the furnaces and heave in the coal to heat them. Other men must draw off the molten charge and pour it into the molds, and still other men must dump the castings from the molds and follow them step by step through the finishing processes and then put them on board the cars for their destination. In each of these operations from beginning to end there is a certain element of danger from the very nature of the materials and because of the fact that human hands must direct each one of them. This element of danger or hazard can be lessened but never eliminated entirely by the installation and use of more modern equipment.

The Human Element

We are asked to discuss today the strides that have been made in the progress of safety work for foundries. Perhaps the greatest stride possible has been made when we recognize the true nature of our problem and put our hands to the task of its solution. We may say with confidence that the foundries of the country have recognized the problem and that they have set about solving it. We may find conclusive evidence of this fact in every new safety device that is installed and in every piece of so-called welfare work that is being undertaken for the workers in our plants. Owners and managers everywhere are beginning to recognize the human element that enters into their safety problem and they are all striking out, some of them blindly, perhaps, to find its solution. We have housing plans. We have gardens by the thousands for our employees. We have clubs and classes. We have entertainments and socials. We have free clinics and visiting nurses and social service workers. We have bonus systems and plans of profit sharing and a score of other lines of welfare work all trying for the one goal of making the worker a more efficient and better satisfied man. All of these things are good and should have a great deal more of our attention. They should be encouraged among our workmen and should be given larger appropriations of money. We have but to look into our own lives to see how easily men are thrown off their guard. We know that a night without proper rest is fatal to our highest efficiency on the day following, and we know that a long stretch of hard work without periods of proper relaxation and recreation will bring about a breakdown in our better judgments. We may not suffer a broken foot from a falling pig of iron or a burned ankle from a splash of molten metal, but we have accidents in our mental processes which are just as painful and a great deal more costly in dollars and cents. Perhaps we should have a great deal more serious accidents than the foundry laborer has if we carried our load and worked where he works and under the same conditions.

Mental Contentment a Great Safety Factor

We know that everything we do in our leisure time has its effect upon our lives while we are at work. The thing that is true of the executive who works in ideal surroundings is still more true of the man who labors with his hands and earns his living in the heat and smoke and confusion of our foundries. To a very large extent he is made or unmade by the things which happen to him outside of his workday life. So then we may say that a divorce suit in a local court may be more dangerous to the man involved than an open pit near his work bench. A threatening landlord may produce more injuries in our foundry than our worst hazard of equipment. In other words, the man whose mind is ill at ease or who isn't properly housed and fed may make our plant more unsafe than it would be if we removed every safety device in the whole place. The man who was just born careless and never outgrew it is more dangerous to our plant when he is in there at work than he would be if he stood off at a safe distance on the outside and hurled firebrands into it three times a day.

The Misfit

Now let us look at some of these men of ours who are so prone to injury. Let us make up our minds to help them if we can. The effort will pay for itself in many ways. First, there is the man who is a misfit. We didn't know there was such an animal a few years ago, but we are beginning to recognize him now. There are men in all of our foundries who ought not to be there. They have been drawn into our employ through a chain of circumstances and it is hard for them to break away. They belong there just about as much as the members of the National Safety Council belong in the business of deep-sea diving. They have about as much sympathy for our business as the average safety

*Abstract of paper read at the Eighth Annual Safety Congress of the National Safety Council, Cleveland, Ohio, October, 1919.

engineer has for the business of the steeplejack. Not having interest in their work, they lack the incentive to become efficient workmen. They drag through the day without enthusiasm and leave when the whistle blows with a full quota of accidents piled up behind them. These are the men who make our State Industrial Commissions keep one eye on our accident charts. It is because of such men as these that we have a high rate of industrial insurance for our foundries of all types.

Need of a Better Understanding of the Men's Abilities

But they are there. Our foreman can point out half a dozen of them any time we ask him. We know they are there, but what are we going to do with them? That question is easier to ask than it is to answer. Perhaps the easiest thing would be to give such a man the opportunity to find work somewhere else. We would have done that in the old days, but we hesitate to do it now; not that we love the man any more than we did, but it is not so easy to replace him with a better man. Another and better solution is to give him his opportunity in some other part of our own plant if possible. We know this plan will work, because we can all call up a great number of individual cases where it has worked. The trouble is that very few if any of us have adopted it as a principle for everyday application. The consistent application of this principle will eliminate a great many of our misfits. It will make careful and efficient workmen out of a great many of our accident makers and will often be the means of keeping a valuable man on our payroll. Of course we can't do this by merely saying that it will be done. If we believe it we must work it day after day, week in and week out. It will call for a closer co-operation between our different production departments and between all foremen and the employment department.

We cannot lay down any rules for the application of this principle. Each case must be handled in its own way. We shall understand our men better; at the very least, our men will understand us better and in this we shall have more of their loyalty and devotion.

The Man With Personal Troubles

The next man who is a great maker of accidents is the man whose mind is ill at ease. He is not so easy to recognize and not so easy to deal with when we do find him. He may be troubled about any one of a score of things and very often there seems to be a combination of nearly all of them. He may be, under ordinary conditions, a very careful and loyal workman, but when "troubles a ton" fall upon him he loses his sense of proportions and all thought of safety for himself or others is crowded out of his mind. The secret of his trouble is that his mind is focused on his own personal problem, so, of course, it cannot be focused on his work. His own personal problems must be met and solved. Every plant needs a squad of sharpshooters who can hit the spot every time. Call them what you will: visiting nurses, social service workers or what not, but first find your men and women who have common sense and good judgment and then turn them loose with authority enough to ride over every precedent and break every rule of the plant if this be necessary to supply the one and only remedy for the worker who is in trouble. These personal contacts with the individuals of our work forces are important and should be carried out just as systematically as our contracts with our best customers.

The next man who makes us lie awake at night wondering what is going to happen next is the careless man. He was born that way or his life has been such that he has grown that way. Nearly all of us are careless to a certain degree, but we find men in all walks of life who are dangerously and criminally careless. We have all known men who continually keep others in trouble on account of their carelessness, but who seem to live under a lucky star and never get hurt themselves.

Educating the Careless Man

The fortunate thing about the careless man is that we can educate him both as an individual and *en masse*. We can appeal to him on the basis of loyalty to his family and the safety of those who work with him. The careless man of our plants can be helped with the "shotgun prescription" in the form of safety bulletins and various other educational activities. A downward curve on the accident chart may be made a matter of pride to them. The most careless man we have may become the most careful if he should suffer a serious hurt as the result of his folly or if he should inflict an injury upon a fellow worker. It should be said, however, that he probably will not rise to this new degree of efficiency on his own account, but that he may be led into it after a heart-to-heart talk with some member of the executive staff. Here again the personal contact is the thing that is most effective in gaining the desired end.

As we shall find some misfits who cannot be "fitted" and some personal problems we cannot solve, so we shall find some careless men we cannot cure. When we find a man like this, the best gift we can bestow is the pay-off slip. Our business has in it so many unavoidable hazards that we cannot afford to be hampered by the man who will not help us to make it as safe as possible.

Environment

Environment is directly related to efficiency and efficiency is a half-brother to safety. The man who works at a rate of speed which is normal to him as an individual will have fewer accidents than he would if he worked a great deal faster or a great deal slower. The piece worker, who, naturally, is interested in maintaining a high degree of personal efficiency, will have fewer accidents than the day worker who takes occasion to kill a block of time now and then. The one is keyed up to his normal pace with mind alert and with attention centered in his task, while the other takes the pace that will keep him out of trouble with the foreman. His mind may be a blank and his attention may be focused anywhere but on his work. It is not difficult to see the relation that exists between each of these men and the accident record of the plant where they work.

We may say with confidence that everything which has a bearing on the productive labor of our men has also a bearing upon our accident experience. Everything which takes the attention of our men from their work will be reflected in the number of accidents we have and everything we do to improve working conditions will mean not only a higher rate of production but also a lower rate of injury.

Responsibility for the environment of the plant does not rest upon the management alone. All who work in the plant have their share in this. The foreman who keeps his department as neat and clean as possible will produce more and better castings than the foreman who allows his men to work in a place that is constantly out of order. Just as the executive will do better work

in a well-appointed office that is kept clear of rubbish, so will the molder and laborer do better work if they are not compelled to climb over miscellaneous piles of slip boxes, bottom boards and broken ladles every time they move about the shop.

Proper Instruction

A man may be a good workman, even a master of his trade, but if he does not know *our* methods of doing work in *our* foundry he may cause any number of accidents to himself and others before he learns. No man should be turned loose alone on a job until he has learned all he can be taught about it. He should know all of its hazards and should be shown how his work is to be related to other work throughout the plant. He will work with more understanding and with a more sympathetic attitude of mind. These have a direct bearing on the question of his making a safe and efficient workman for us. The task of giving him this information should be assigned to a definite group of qualified men and the new man's acknowledgment of having received such instruction be made a part of his record.

All of these problems were greatly minimized in the old days when the workman lived in the home of his employer. The complexities of modern life will never permit us to return to this condition, but we must approach the ideal of the constant personal contact with our workmen if we would seek to minimize the problems of this our present day.

That there is nothing that is entirely new or original in the subject matter of this paper is well known to the writer. It is only hoped that by bringing these same things to our attention again and again we can be brought to see anew our obligation to those who work for us and with us. There is nothing new to be brought forward in this problem. It is the old problem of the relation between men. We have not entered into any new obligation to our men in this new day of great industrial activity. Our obligation is the same if we have one man or a thousand men working for us. It is that we shall give them all we can of ourselves so long as they are faithful and loyal and continue to give us the best that is in them.

Marion, Ind.

Lewis Impact Machine

LIEUTENANT COMMANDER A. G. ZIMMERMANN, of the United States Naval Gun Factory, presented a very important discussion of Dr. F. C. Langenberg's paper on "Experimental Data Obtained on Charpy Impact Machine," during the recent Chicago meeting—briefly mentioned in CHEMICAL & METALLURGICAL ENGINEERING, Oct. 8, 1919 (vol. 21, p. 461). Mr. Zimmermann's remarks in which he describes the theory and operation of the curve-drawing vertical-drop machine devised by Lieutenant G. Q. Lewis, U. S. N., follow at length:

Dr. Langenberg's work serves to demonstrate the correctness of two principles which should be the basis of all inspection by the consumer of materials subject to shock where impact testing machines are not available or where the data on results with impact testing machines are not considered conclusive enough to form the basis for specifications.

These two principles are: (*a*) Acceptance of forgings need not necessarily be based on the performance of test bars pulled in the direction of the stresses that will be applied in service. (*b*) Material that has normal ductility in its weakest plane is a good shock-resisting material.

The first principle follows the fundamental idea that if the most unfavorable test of the material is definitely known, the inspector has good grounds for assuming that the remainder of the forging is as good or better, when viewed from any other angle, as the results on which he accepted the forging. This is the more reasonable since, as pointed out by Dr. Langenberg, it is not always safe to say that no transverse stresses will be set up when, theoretically, the stresses of service are longitudinal.

If the location of test specimens is to be determined beforehand, irrespective of the method of forging, there would be an undue incentive to the manufacturer to do excessive forging in the direction of the test specimen. It is undoubtedly true that the more forging material receives in one direction, beyond a certain point, the less will be its ductility at right angles to this direction—and this effect is much more marked in basic steel than in acid steel. Since sudden shock appears to search out the weakest plane of a forging, it is apparent that normal ductility in one direction should not be sacrificed for a good showing in ductility in another direction.

Naval Bureau of Ordnance Uses Langenberg's Principles

Dr. Langenberg's results, showing that the impact test follows somewhat the course indicated by the results of the transverse static test, are borne out by the fact that the Naval Bureau of Ordnance has been following the above principles of inspection for some time and a consultation of the records fails to disclose any failures of material in service that have been traceable to the failure of accepted material under normal shock conditions. However, impact tests should be the principal criterion of any shock-resisting material, and it is hoped that their use in both commercial and ordnance work will rapidly come into favor. It is considered imperative, however, for the general use of such a test, that conditions should be standardized in the beginning, so that no confusion or change of equipment will result upon the incorporation of a standard test in the specifications.

Standard Practice for Impact Test

It is considered that there should be an early decision as to standard American practice in the following particulars, in order that the impact test may become a part of the routine procedure of buying materials subject to sudden stresses:

1. A selection of either the pendulum or the vertical-drop type of impact testing machines.
2. A selection of either notched or unnotched bars.
3. If notched bars are selected, the immediate selection of a standard notch, so that the practice of playing with various types of notches, such as has been done in other countries, be nipped in the bud, and some consistent data will quickly be assembled.
4. If possible, the adoption of an impact test whereby the resistance of the material can be reduced to an

equivalent of lb. per sq.in., which will have a more definite meaning to the ultimate consumer of this country and will obviate the necessity of a tabulation of new units in the customary reports of physical test.

This last point is not so far removed from possibility as it may seem at first glance. What appears to be a very workable arrangement has been devised at the United States Naval Gun Factory, for use with a vertical-drop machine, by Lieutenant G. Q. Lewis, of the Navy, who was assigned this task in connection with the contemplated activities of the enlarged physical laboratory of the Gun Factory.

Description of Lewis Machine

The essential features of the apparatus consist of a weight *A*, Fig. 1, which is guided by a central shaft *B* and can fall from any predetermined height, striking a hardened plate *D* and rupturing in tension the standard test bar *C*, the ends of which are screwed into the lower end of the shaft *B* and the plate *D*, respectively. A bracket *E* suitably secured to the weight *A* engages a plunger *F* of a device that amplifies the vertical movement of the weight just before and during the period of rupture. A pencil record of the amplified movement is made upon a paper cylinder mounted on a drum *G*, which is rotated at a known constant speed by the motor *H*. The object of the amplification is to obtain a space-time curve of such

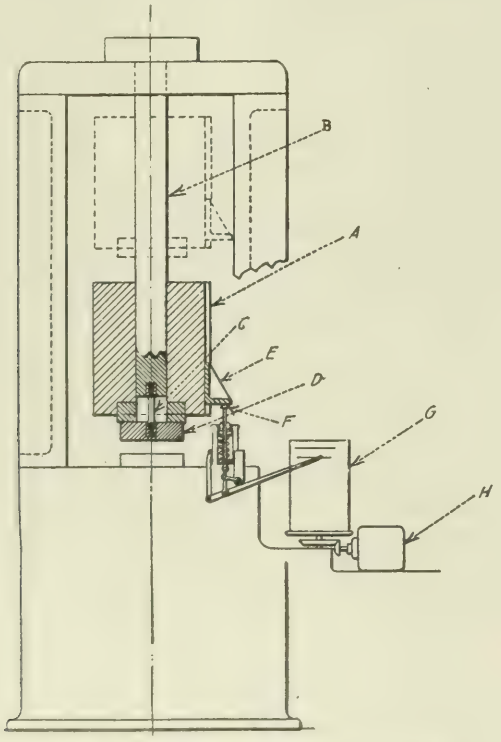

FIG. 1. VERTICAL DROP MACHINE

proportions that a graphic or protractor analysis may be conveniently and accurately made and the resisting value of the material tested derived in terms of lb. per sq.in.

Relation Between Elongation and Time

The curves obtained show the relation of the elongation of the test bar with reference to time. For a typical curve (see Fig. 2), the elongation would be measured vertically and the time horizontally to known scales, depending on the amplification and surface speed of the drum. The weight, being released from a suitable predetermined height, accelerates uniformly and attains maximum velocity at a certain point *J* where the pencil line crosses a horizontal base line *KL*, previously scribed on the drum with the weight resting on the plate *D*, Fig. 1, which is screwed to the lower end of the test bar. The tangential motion of the paper drum being to the left, the rupture curve is drawn

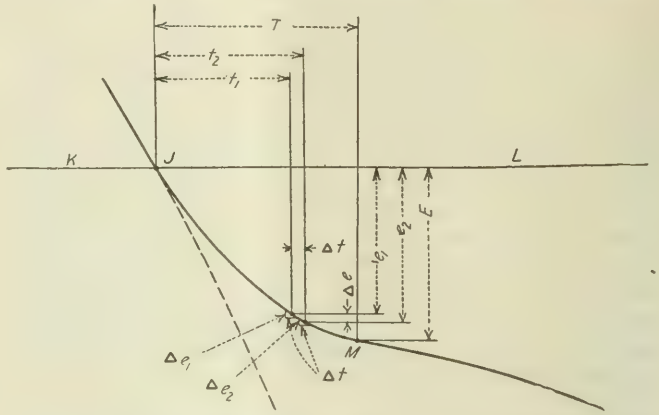

FIG. 2. RELATION OF ELONGATION OF TEST BAR WITH REFERENCE TO TIME

downwardly and to the right. Above the base line is recorded the last portion of the parabolic free fall of the weight and below is recorded the movement of same as retarded by the resistance of the test bar. The curve reverses after crossing the base line and the slope of the same decreases as the bar elongates, owing to the reducing velocity of the weight. After rupture occurs at M, the curve reverses and the weight again accelerates, due to gravity.

Analysis of the Results

Analysis of the curve between the initial and the final points of test-bar resistance gives the average forces of retardation corresponding to increments of elongation, Δe, measured normally to the base line. To determine the average retarding force during any time increment Δt, the slopes or tangents of the curve are first obtained at the beginning and the end of the time increment Δt, to determine the corresponding instantaneous velocities of the weight at these points. Thus the tangent to the curve or its equal, the instantaneous velocity of the weight at the beginning of time increment $\triangle t$, is $\frac{\triangle e_1}{\triangle t}$ and at the end is $\frac{\triangle e_2}{\triangle t}$. The acceleration during the period $\triangle t$ is $\frac{\triangle e_2 - \triangle e_1}{\triangle t^2}$.

The average force of retardation F, in pounds, during any increment of time Δt, therefore, equals the product of the mass and the acceleration, or $K\frac{\triangle e_2 - \triangle e_1}{\triangle t^2}$, where K is a constant depending on the mass of the weight and the units employed in measuring Δe and Δt. F will be algebraically negative because the acceleration is negative. Thus the stress, exerted by the test bar to resist the retardation force of the weight W, will be $+F$, since it is equal but opposite in direction to that imposed by the weight. The total stress in the bar will then be algebraically equal to $W + F$, where W is the number of pounds in the weight, also resisted by the test bar because of gravitation.

It is not to be assumed that calculations of this description will be necessary for each specimen pulled,

as a protractor has been designed which will integrate the space-time curve throughout the entire elongation period of the specimen and thus permit a ready selection of critical values, read directly in lb. per sq.in.

Advantage of the Lewis Testing Method

While Lieutenant Lewis, who has now returned to his former activities in the supplying and testing of railroad materials, had the benefit of previous research in connection with railroad shock absorbers, it is considered that this method of analysis is considerably different from any performed before, in that it goes further and gets an expression of the strength of material, in pounds per square inch, which is a function of the amount of energy expended in rupturing the specimen.

Oil Pipe Lines*

By S. A. Sulentic

THE object of this paper is to show the advantages of the oil engine as a means of transporting oil for long distances through pipe lines, to compare the cost of pipe-line transportation with that of rail and canal transportation, and to derive simple formulas that will make it comparatively easy for any one to make quick calculations of the pressure, net horsepower and brake-horsepower necessary for the transmission of any quantity of oil per day through a pipe of known diameter.

The cheapest method of overland transportation of oil is by pipe line. The cost in comparison to rail transportation is low, and yet when the rail cost is based on everyday practices, the amount seems very small. For instance, the management of an Eastern railway, wishing to impress upon its clerical employees the importance of economy, posted the following notice: "For every lead pencil you waste we have to haul one ton of freight one mile."

The cost of a pencil has always been regarded as being insignificant, but when it is considered that it is equivalent to the cost of the above-mentioned haul, a similar comparison with pipe-line transportation should be interesting. The carrying of one ton of freight for one mile at the cost of a lead pencil is very cheap transportation. One or two cents per ton-mile is a low rate. Canal transportation, after allowing for the proper fixed and maintenance charges, may be lower than the rail charges by 60 per cent or even more.

In order to make a very crude estimate of the cost of transporting oil by pipe line when using equipment of the highest economy, assume a single line operating under the following conditions at a load factor of 80 per cent for 300 days per year:

Size of line, in.	8
Length of line, miles	33
Pressure of line, lb. per sq.in.	700
Rate of discharge, bbl. per hr.	900

At this rate the discharge would be 21,600 bbl. per day, or 6,480,000 bbl. per year of 300 days. Assuming 6.5 bbl. per ton, the yearly discharge would approximate 1,000,000 tons. The work equivalent of this discharge would be 33,000,000 ton-miles, calling for the continuous expenditure of 257 hp. Assuming the mechanical efficiency of the engine to be 75 per cent, the actual horsepower necessary to install would be 257 ÷ 0.75, or 342.

The assumed costs would be as follows:

Line: 33 miles at $1.65 per ft.	$287,500
Right of way at $0.25 per rod	2,640
Freight: 79 cars at $250	19,750
Haulage: 900 tons at $14.50	13,050
Laying pipe at $0.075 per ft.	13,060
Burying pipe at $0.20 per ft.	34,850
Engines, pumps, installed accessories	68,500
Pump stations, buildings and foundations	30,000
Tanks { Two 55,000-bbl. at $18,500 each	37,000
Tanks { Two 500-bbl. at $500 each	1,000
Telegraph line: 33 miles at $550	18,150
Superintendence	2,500
Incidentals	6,000
Total assumed costs	$534,000

The operating expense, including fixed charges based on the total assumed costs, would be as follows:

Interest at 6 per cent	$32,040
Depreciation at 5 per cent	26,700
Administration	10,000
Attendance at pump stations and lines	11,500
Repairs to equipment, lines, etc.	4,000
Fuel for pumping—3,000 bbl. at $2.65	7,950
Total operating expense	$92,190

Hence the cost of operation per ton-mile under the assumed conditions would be $92,190 ÷ 33,000,000 = $0.0028, or two and eight-tenths mills per ton-mile. As the relation between the cost of pipe-line transportation and rail transportation is in the ratio of 1 to 10, it is easily seen that the waste of a lead pencil in a pipe-line enterprise would be the equivalent of the cost of transporting 10 tons of oil one mile.

Considerations in Estimating Cost

It should be noted, however, that almost all of the pipe-line costs are fixed and are mainly independent of the amount of oil pumped. As a result, the transportation cost per ton-mile will vary almost inversely with the load factor of the line. If this hypothetical pipe line should be operated only one-tenth of the time assumed, the unit transportation cost would equal the rail cost. Furthermore, these figures are based on a life of 20 years (5 per cent amortization). A railroad would probably be used for various classes of freight as long as it existed, but a pipe line is of service only as long as oil is presented for transportation. If the pipe line in question were to become obsolete in ten years through the exhaustion of the oil fields or other causes, the ton-mile cost would be greatly increased.

These figures have not been presented as those of an average case but only offered as "food for thought." In further consideration of the subject, however, it will not be out of place to give a few figures and examples showing the relations existing between pressure, capacity, diameter, length of line and power required.

Disregarding viscosity, the general hydraulic formula for friction head in a pipe discharging a uniform volume is

$$F = k\frac{v^2 L}{2gD} \qquad (1)$$

in which

F = friction head in feet of water = lb. per sq.in. ÷ 0.433
k = friction coefficient for 38 gravity oil = 0.024
v = velocity of flow, ft. per sec.
g = acceleration of gravity = 32.2 ft. per sec. per sec.
L = length of line, ft.
D = diameter of line, ft.

The formula for pressure in the line may be stated as

$$P = 0.433k\frac{v^2 L}{2gD} \qquad (2)$$

in which P = pressure in line in lb. per sq.in.

*Presented at the annual meeting, Dec. 2-5, 1919, of the American Society of Mechanical Engineers, New York.

The discharge Q of the line, cu.ft. per sec., can be easily derived and stated as

$$Q = \frac{\pi D^2 v}{4} \qquad (3)$$

in which Q varies directly as v. Since P varies directly as v^2 in Formula (2) and Q varies directly as v in Formula (3), it follows that P varies directly as Q^2.

The net horsepower required for a pipe line may be most readily calculated if we note that the pressure per sq.ft. is equal to the number of foot-pounds required to displace 1 cu.ft. of oil, or

$$\text{Hp.} = \frac{144PQ}{550} \qquad (4)$$

For 1,000 bbl. per day against a pressure of 1,000 lb. per sq.in., the net hp. necessary by Formula (4) would be

$$\text{Hp.} = \frac{144 \times 1{,}000}{550} \times \frac{1{,}000 \times 5.61}{24 \times 60 \times 60} = 17$$

where 5.61 = cu.ft. per bbl.

Assuming a pump efficiency of 85 per cent, the horsepower of the engine would be 17 ÷ 0.85, or 20. Here we have a very simple rule for calculating the horsepower from bbl. per day and pressure in lb. per sq.in.; namely,

Net hp. = 17 × thousands of bbl. per day × P ÷ 1,000

B.hp. = 20 × thousands of bbl. per day × P ÷ 1,000

For example, for a discharge of 8,000 bbl. per day against a pressure of 600 lb. per sq.in., the brake-horsepower required would be 20 × 8 × 0.6, or 96. Since the horsepower varies directly as PQ and P varies directly as Q^2, it follows that hp. varies directly as Q^3. To sum up:

Velocity varies directly as the line discharge.

Pressure varies directly as the square of the line discharge.

Horsepower varies directly as the cube of the line discharge.

Another relation of value in making rapid pipe-line calculations is the ratio between the diameter D and length L, with the discharge Q and the pressure P remaining constant.

From the friction formula (2) it will be seen that P varies directly as $v^2L \div D$. Assuming P constant, L varies directly as $D \div v^2$. For the same discharge, Formula (3), that is, with Q constant, v varies directly as $1 \div D^2$. Therefore v^2 would vary directly as $1 \div D^4$. Substituting this value for v^2 above, it is seen that L varies directly as $D \div (1 \div D^4)$, or in other words, L varies directly as D^5.

This means that for the same discharge and pressure, i.e., the same friction, the length of the line would vary directly as the fifth power of the diameter. Taking a diameter of 6 in. as unity, the fifth powers of several different diameters are as follows:

D =	6	8	10	12
D^5 =	1.0	4.2	12.8	32

An example will show how easily these relations are utilized. Let a proposed pipe line be made up as follows:

Two 6-in. lines, 8 miles long (Y-branch).
One 6-in. line, 6 miles long.
One 8-in. line, 10 miles long
One 12-in. line, 12 miles long.

With the particular oil to be transported the pressure per mile when pumping 10,000 bbl. a day through a 6-in. line will be assumed as 20 lb. per mile. What, now, will be the pressure for 17,000 bbl. per day through above line and what will be the net hp. and b.hp. required?

Since P varies as Q^2, the pressure for 17,000 bbl. will be $(17{,}000 \div 10{,}000)^2$, or 2.89 times the pressure for 10,000 bbl. The pressure in the line would then be 2.89 × 20, or 57.8 lb. per mile.

Inasmuch as the velocity is halved when using two 6-in. lines for the 8-mile section, each line carrying an equal amount of oil, the equivalent length of 6-in. line for each branch would be only two miles, the length varying directly as the square of the velocity. The length of 6-in. line equivalent to the 8-in. pipe would be 10 miles divided by the ratio of the fifth powers of the diameters 6 in. and 8 in., or 10 ÷ 4.2 = 2.38 miles. In a like manner the length of 6-in. line equivalent to the 12 miles of 12-in. pipe would be 12 ÷ 32, or 0.37 mile. In other words, the equivalent length of 6-in. pipe in the line under consideration would total 12.75 miles. Under a pressure on the line of 57.8 lb. per mile, the total pressure on the line would be 12.75 × 52.8, or 737 lb.

Making use of the simple formula for hp. already derived we have

$$\text{Net hp.} = 17 \times \frac{17{,}000}{1{,}000} \times \frac{737}{1{,}000} = 213$$

$$\text{B.hp.} = 20 \times \frac{17{,}000}{1{,}000} \times \frac{737}{1{,}000} = 250$$

No doubt many other useful relations could be derived for the purpose of expediting pipe-line calculations, but those which have been presented are among the most useful.

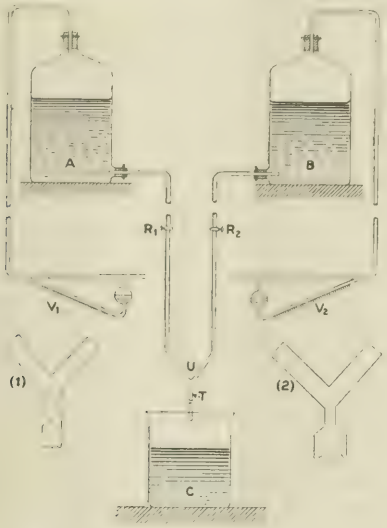
In illustration of the foregoing the following data in regard to the 36-mile, 8-in. Alton pipe line operating between Carlton and Wood River, Mo., should prove of interest. This line, constructed in 1913, has four stations, in each of which are installed four units each consisting of a 100-hp. type F. H. De La Vergne oil engine direct-connected to a 6-in. by 18-in. National Transit Co. herringbone-geared power pump with 8-in. suction and 6-in. discharge. The performance of one station equipment (three units) is given below:

Oil pumped during 10 days, bbl.	140,000
Oil pumped per day, average, bbl.	14,000
Pressure maintained in line, lb. per sq.in.	700
Brake horsepower, average	196
Pump efficiency, estimated, per cent	85
Fuel consumed by engines during 10 days, bbl.	65.8
Fuel consumed by engines per day, lb.	2,020
Brake-horsepower-hours per day = 196 × 24	4,704
Fuel consumption per b.hp.-hr., lb.	0.43
Ft.-lb. of work per day developed by the engines = 196 × 33,000 × 24 × 60	9,320,000,000
Ft.-lb. of work per day in oil pumped = 9,320,000,000 × 0.85 (85 per cent efficiency)	7,900,000,000
B.t.u. in fuel consumed per day = 2,020 × 18,000	36,000,000
Ft.-lb. of work per 1,000,000 B.t.u.	217,000,000
Daily operating cost:	
Fuel oil: 6.58 bbl. at $1.50	$9.87
Lubricating oil: 2 gal. at $0.22	0.44
Cylinder oil: 1.6 gal. at $0.21	0.34
Attendance: Total salaries of 2 engineers, 2 assistant engineers, 1 chief engineer and 2 telegraph operators	41.50
	$52.15
Cost per b.hp.-hr. ($52.15 ÷ 4,704)	$0.011
Cost per bbl. of oil pumped ($52.15 ÷ 14,000)	0.0037
Bbl. of oil pumped per bbl. of fuel consumed (14,000 ÷ 6.58)	2,130

In conclusion it may be said that the comparatively small amount of power involved in pipe-line transportation lends itself admirably to the efficient use of the oil engine as a prime mover. And unless some other form of power can show better results in the immediate future, the oil engine bids fair to hold its present superiority as a means for the transportation of oil.

Synopsis of Recent Chemical and Metallurgical Literature

Homogeneous Liquid Mixtures.—PIERRE JOLIBOIS has devised a very convenient apparatus for producing a homogeneous mixture of liquids in a very short time. The principle of the apparatus is described in the Dec. 8, 1919, issue of *Comptes Rendus*. The accompanying illustration shows the principle involved. The quantities of the liquids used are measured by the graduated venturi tubes, V_1, V_2. The diameter of the tube T and its shape have a great influence on the time required for homogeneous mixing.



APPARATUS FOR PRODUCING QUICKLY A HOMOGENOUS MIXTURE OF LIQUIDS

To render this visible to the eye he used in A a solution of potassium permanganate (1.58 g. per liter) and in B a solution of ferrous sulphate (15 g. $FeSO_4$, 50 c.c. conc. H_2SO_4 and 10 g. $MnSO_4$ per liter). The rapidity of the flow of liquids from the bottles A and B is regulated by the valves R_1 and R_2.

With a flow of 500 c.c. per min., the following data were obtained:

Dia. of Tube, Mm.	Length of Still Colored Liquid in Tube T, Cm.	Time Required to Obtain Homogeneity, i. e., When the Liquid Becomes Colorless, Sec.
2.5	4.0	0.04
3.2	6.5	0.08
4.8	10.0	0.2
6.2	22.5	1.0
8.5	33.0	1.2

The influence of the shape of the Y tube is shown by the following results:

Shape	Dia. of Tube in Mm.	Length in Cm. of Still Colored Liquid in Tube T	Time to Obtain Homogeneity, Sec.
Straight Y	6.2	22.5	1.00
1	6.2	4.0	0.12
2	6.2	2.6	0.01

The shape 2 has been adopted. This apparatus will be of great help in the study of the rapidity of reactions between liquids.

Catalytic Preparation of Ether.—The preparation of ether from alcohol by the use of moderately calcined commercial alum catalyzer has been studied experimentally by A. MAIHLE and F. DE GODON, in order to determine the influence of temperature, degree of alcohol and amount of catalyzer, and is described in the October, 1919, issue of *Bulletin de la Société Chimique de France*. The catalyzer is placed in a glass tube and heated, alcohol drips into the tube and vaporizes, the outgoing vapors are condensed and the ether is extracted from the catalyzed product.

Influence of Temperature. There was catalyzed 100 c.c. of 95 deg. alcohol in a glass at 175, 185 and 190-195 deg. C. The amounts of 0.725 density ether obtained were 10, 15, 20 c.c.; i.e., 11.8, 17.7 and 23.6 per cent efficiency respectively. This indicates that the best working temperature is 190-195 deg. C.

Influence of Degree of Alcohol. The following results were obtained when working on 100 c.c. of different degrees of alcohol under the same conditions of temperature and catalyzer:

Deg. Alcohol	Ether 0.725 Dens.	Efficiency
95	42	49.8
90	38	47.7
80	28	39.6
60	17	32.2

This shows that although 95 deg. alcohol gives the best results, it is possible to obtain relatively fair results from lower degrees of alcohol.

Influence of Amount of Catalyzer. When using the same amount of catalyzer but spread on a larger area, the results are not improved. By increasing the amount of catalyzer the efficiency increases as follows: 100 c.c. 95 deg. alcohol at 195 deg. C. gives with a 34-g. catalyzer 23.6 c.c. 0.725 ether; with a double 34-g. catalyzer 42 c.c. ether; with a quadruple 34-g. catalyzer 53 c.c. ether, and with a quadruple 42-g. catalyzer, 60 c.c. 0.725 ether, i.e., respectively 23.6, 49.8, 63 and 71.3 per cent efficiency.

The conclusions to which they arrived are:

1. Possibility of use of a cheap catalyzer, such as commercial alum.

2. Use of relatively low temperature, 195 deg. C. being the highest and at the same time the best suited for efficient results.

3. The ether obtained is pure, with no formation of ethylene and only traces of aldehyde.

4. Alcohols of even 55 to 60 deg. can be used with relatively fair efficiency.

Production of Hydrocyanic Acid.—The December, 1919, issue of *Helvetica Chimica Acta* contains a description of the research work of E. BRINER and A. BAERFUSS on the production of hydrocyanic acid. All the hydrocarbons mixed with nitrogen give HCN under the action of electric discharges. They have used pure methane and nitrogen with and without the admixture of hydrogen. The mixture of gases circulate at a rate of 8 to 10 liters per hr. in a chamber in which electric discharges take place. By using platinum electrodes spaced 7 mm. apart and with a current of 0.02 amp. under varying compositions of the gaseous mixture, voltages and pressures, the following results were obtained:

Composition of the Gaseous Mixture	Voltage	Pressure of Gaseous Mixture, Mm. Mercury	Efficiency G. per kw. hr. HCN	Efficiency G. per kw. hr. NH_3	Concentration HCN per Cent Volume
$12CH_4 + 23N_2 + 65H_2$....	1,020	635	0.46	0.14	0.08
$11CH_4 + 54N_2 + 25H_2$....	1,030	600	2.15	0.01	0.38
$CH_4 + N_2$.....	450	100	3.88	0.44	0.80
$CH_4 + 3.5N_2$.....	500	100	5.12	0.52	0.44
$CH_4 + 5N_2$.....	505	100	7.39	0.48	0.75

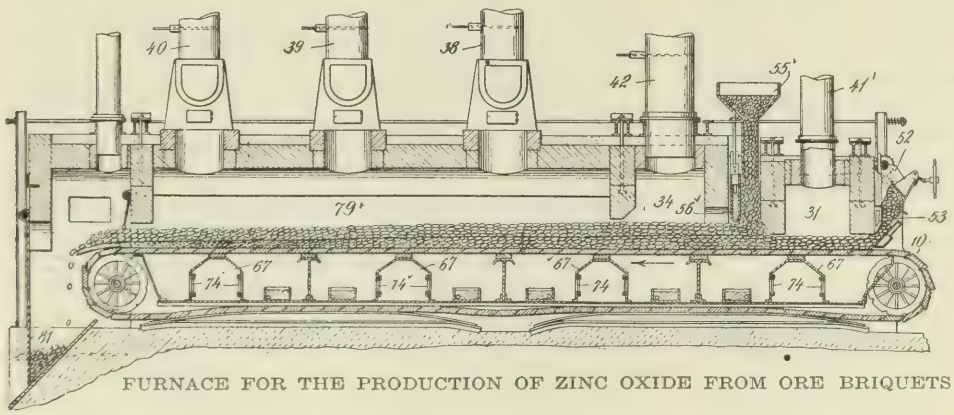
They conclude that when working on a mixture with an excess of nitrogen under low pressures the results are far more satisfactory than when working under high pressure.

Recent Chemical and Metallurgical Patents

Complete specifications of any of the United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Production of Zinc Oxide.—A series of patents assigned to the New Jersey Zinc Co. disclose improvements in the production of metal oxides and other compounds of metals by volatilization. In the production of zinc oxide by means of the Wetherill process the furnace grate is charged with a layer of "buckwheat" anthracite, which is ignited by the residual heat of the previous charge and a rapid combustion of this coal produced by forcing a blast of air through the perforated grate. Upon this ignited bed of coal is charged a mixture of finely divided coal and zinkiferous material termed the "working charge." The air blast is continued and when the volatilization is begun the fume is conveyed through cooling towers and collected in a baghouse. There are certain defects in this method. The formation of blowholes in the charge produces hot spots, making it necessary to work the charge by hand rabbling; in this way dust is carried off with the fume. Further, the necessity of maintaining a porous charge limits the fineness of the materials that can be used successfully. These and other objections are overcome by briquetting the fuel, which may be any carbonaceous material such as the smaller sizes of buckwheat coal, colliery washings or coke breeze, and also briquetting the zinkiferous material with the necessary amount of similar carbonaceous material. The fuel briquets are charged on the grate in the same manner as the "buckwheat" anthracite and after ignition the "working charge" briquets are added. (F. G. BREYER, J. A. SINGMASTER and A. E. HALL, 1,322,088; Nov. 18, 1919.)



FURNACE FOR THE PRODUCTION OF ZINC OXIDE FROM ORE BRIQUETS

As the Wetherill process is usually conducted, from 15 to 25 per cent of the total carbonaceous material is charged as the fuel bed, the remaining 85 to 75 per cent being mixed with the zinkiferous material. All of the ash of the coal is mixed with the residue; this residue has a value depending somewhat upon the amount of ash with which it is contaminated for the recovery of metals that are non-volatile under furnace conditions, also for the production of spiegeleisen, etc. When using the fuel and ore in the form of briquets, only 15 to 25 per cent of the fuel need be briquetted with the ore, the remainder being used as fuel briquets. Under these conditions the work-off ore briquets retain their original shape and can be readily separated from the ash of the fuel. This not only increases the value of the residue but increases recovery to about 90 per cent, which is about 20 per cent greater than with the usual method. (F. G. BREYER, A. E. HALL, G. R. WALTZ. 1,322,089; Nov. 18, 1919.)

The details worked out as above are applied to the production of sublimed lead and leaded zinc oxide and other compounds of metals as well as to zinc oxide. (F. G. BREYER, A. E. HALL, G. R. WALTZ. 1,322,090; Nov. 18, 1919.)

It is possible to briquet a certain amount of ore containing zinc or lead or both with the fuel briquets, or to briquet the ore without the addition of a reducing agent. These and other combinations are incorporated. (F. G. BREYER, J. A. SINGMASTER, A. E. HALL. 1,322,091; Nov. 18, 1919.)

The usual Wetherill process for the production of zinc oxide is conducted in a block furnace containing several grates, with the idea of providing zinc oxide continuously by controlling the sequence of operations, the operation on the individual grates being intermittent. The use of the fuel and ore in the form of briquets simplifies the design of a furnace in which the operation can be carried out continuously. Such a furnace is shown in the figure. The chain or other similar grate 10 is moved in the direction of the arrow about 7 ft. per min. The fuel briquets are charged through hopper 52, being spread by a water-cooled gate 53, the vertical movement of which controls the amount of feed. The charge is ignited and the gases escape through flue 41. The ore, also in the form of briquets containing 15 to 25 per cent carbonaceous material, is fed through hopper 55, being spread by a water-cooled gate 56, which also controls the amount of feed. Products of combustion, together with a small amount of metal oxides, are carried off through flue 42. The major portion of the metals is reduced, volatilized and oxidized in the fume chamber 79, which is about 18 ft. in length, and is carried off through flues 38, 39 and 40. Air under pressure is supplied beneath the grate through tuyeres 74 in the side of air-box 67. The worked-off ore briquets are discharged into hopper 81 in substantially their original form. The ash from the fuel briquets is in the form of disintegrated clinker and may be readily separated from the ore briquets. The bed of fuel briquets used is about 6 in. deep and the bed of ore briquets about 3 in. deep. Chamber 31 is maintained at a temperature of between 800 and 850 deg. C., which is a minimum temperature for uniform ignition. Satisfactory working temperatures for chamber 34 are from 1,000 to 1,050 deg. C. and for the fume chamber 79 from 1,100 to 1,250 deg. C. The temperature is controlled by slide dampers located in the air flue leading to air chambers 74 and also by dampers in the flues 38, 39, 40 and 42. A recovery of about 90 per cent of the volatile metals is obtained at a considerable reduction in labor. The quality of the product is also improved due to the avoidance of dust. (J. G. SINGMASTER, F. G. BREYER and E. H. BUNCE. 1,322,142; Nov. 18, 1919.)

The furnace and details are applied to the production of sublimed lead, leaded zinc oxide and other compounds of metals as well as to zinc oxide. (J. G. SINGMASTER, F. G. BREYER and E. H. BUNCE. 1,322,143; Nov. 18, 1918.)

Electrolytic Oxidation of Benzene to Quinone.—The oxidation of benzene to quinone is accomplished in the anode compartment of an electrolytic cell. The lead anode is provided with a large number of staggered projections so that the benzene, which is introduced through a perforated tube near the bottom of the electrode, is forced to follow a devious course in rising to the surface of the electrolyte (10 per cent sulphuric acid). A current density of 0.5 amp. per sq.dm. is used and the temperature is kept below 12 deg. C. An excess of benzene is used, so that the quinone formed remains in solution. This solution of quinone in benzene is removed to a reduction tank, where it is treated with sulphurous acid. The quinone is reduced to quinol (hydroquinone), which may be recovered from the aqueous solution by evaporation. The excess benzene is returned to the electrolytic cell. (1,322,580; FREDERICK T. KITCHEN, of West Brighton, N. Y., assignor, by mesne assignments, to K. & T. Chemical Corp.; Nov. 25, 1919.)

Pickling Baths.—WILLIAM H. ALLEN, of Detroit, Mich., notes that an ordinary pickling bath, as of sulphuric acid, attacks clean iron so much more rapidly than its adherent scale that sheets often emerge badly corroded. In order to reduce these higher iron oxides so they may more readily go into acid solution, he recommends the addition of about one-fifth the amount of sulphurous radical, by bubbling SO_2 or adding sodium bisulphite or hyposulphite. Other reducers which may be effectively used in the ordinary baths of sulphuric, hydrochloric or phosphoric acid are phosphorous acid, H_2S, Na_2S, or phosphides of iron or zinc. All of these produce active reducers, but great care is necessary in their use, as some products are violently poisonous or highly explosive. (1,321,182; Nov. 11, 1919.)

Book Reviews

STORING, ITS ECONOMIC ASPECTS AND PROPER METHODS. By *H. B. Twyford.* 252 pages, 6 x 9. 112 charts, diagrams and forms. New York, 1918: D. Van Nostrand & Co.

This work brings out splendid points in favor of giving the store department more consideration and attention than it usually receives from the managers of most industrial firms. The proper receiving, storing and distribution of supplies are an important factor in the welfare of any business institution.

On page 81 the author states that material can be placed on the shelves "at any time to suit conditions," while he contradicts on page 98 with "Prompt handling of all material as it arrives is an essential feature of successful storekeeping." The latter, of course, is true.

Prominent organizers of store departments of large concerns differ with the author in that they are opposed to the use of the perpetual inventory. The receiving clerk should not be separated from the store department, as recommended, but should report receipts to the storekeeper, who, in turn, notifies the purchasing agent. Excellent ideas are advanced for records of receipts of material. Provision for return of such goods as are not immediately used to the storehouse is also good.

The careful study of this book by the younger members of the store department forces would yield them valuable information, but discretion must be used in accepting any of the technical theories advanced. E. G. WALKER.

* * *

SELENIUM CELLS AND HOW THEY ARE MADE. By *Samuel Wein.* 34 pages. New York: Progress Publishing Co.

This small book is of tablet form and contains a chronological survey of information concerning selenium and selenium cell construction. It has been written expressly for the investigator who is interested in the variation of the electric conductivity of selenium in the presence of light. While it may be justly criticized because of being overly concise, it does contain a great amount of valuable data as well as bibliography for the guidance of the reader.

WALLACE SAVAGE.

Personal

ALBERT BRETON, formerly vice-president of the Guaranty Trust Co., New York, has been elected president, to succeed GRAYSON M. P. MURPHY, who resigned to assume the presidency of the newly-formed Foreign Commerce Corp. of America.

ARTHUR R. CADE, formerly instructor in chemistry at the University of Minnesota, Minneapolis, Minn., is now associated as research chemist with the National Carbon Co., Fremont, Ohio.

JOHN J. CARTY, vice-president of the American Telephone & Telegraph Co., lectured under the auspices of the National Research Council on Feb. 6. The subject was "Science and the Industries."

Dr. VIRGIL COBLENTZ, formerly professor of chemistry in the New York College of Pharmacy and later chemical director of E. R. Squibb & Sons, Brooklyn, N. Y., and N. W. KEMPT, chemical engineer, will engage in professional consulting practice, with offices at 119 Nassau St., New York City.

Dr. HARRY A. CURTIS has resigned his professorship at Northwestern University, Chicago, to accept a position with the International Coal Products Co., New York.

WALTER S. ERNST, formerly employed as a chemist at the U. S. Nitrate Plant No. 1, Sheffield, Ala., is now chief chemist for the Ironton Portland Cement Co., Ironton, Ohio.

J. A. L. GALLARD, who was mining editor of the *Financial Times* for eighteen years, has joined the staff of the *Mining Magazine* as associate editor.

HAROLD GRAY, who has been on the research staff of Eli & Co. of Indianapolis, Ind., for the past four years, is now on the research staff of B. F. Goodrich Co., Akron, Ohio, in the organic development department.

G. P. HULST has resigned as assistant general manager of the East Chicago plant of the International Lead Refining Co. and will be succeeded by GUNNARD E. JOHNSON.

MILO W. KREJCI has become works manager for the Parish-Pool Co., Cleveland, Ohio. During the past few years Mr. Krejci has developed an electrolytic process for making a white lead and supervised the construction and operation of a commercial plant working under this process for the International Lead Products Co.

CLARENCE E. MEISSNER has accepted a position with the Inspiration Consolidated Copper Co., Inspiration, Ariz.

CHARLES F. RAND, who has been president of the United Engineering Society since 1917, has retired, his term having expired. By constitutional limitation he was not eligible for re-election. As an appreciation of Mr. Rand's services the board of directors of the American Society of Mechanical Engineers presented him with engrossed resolutions. J. VIPOND DAVIES succeeds Mr. Rand.

Provost EDGAR FAHS SMITH, of the University of Pennsylvania, has tendered his resignation, to take effect at the end of the present academic year, which will complete his forty-fourth year as a teacher.

E. K. SOPER, who has been with the Trinidad Petroleum Development Co. at Port of Spain, Trinidad, is now located at 120 Broadway, New York City, with the Sinclair Oil & Refining Co.

GEORGE J. YOUNG, Western editor of *Engineering and Mining Journal*, is in New York City to attend the meeting of the American Institute of Mining and Metallurgical Engineers.

Current Market Reports

The Non-Ferrous Metal Market

New York, Feb. 16—Copper market steady with little new business. Tin has advanced ¼c. over last week's quotation. Slight advances in lead, tin and silver.

	Cents per Lb.
Copper, electrolytic	18.75
Aluminum, 98 to 99 per cent	31½@32½
Antimony, wholesale lots	11.50
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	57.75
Lead, New York, spot	8.87½
Lead, E. St. Louis, spot	8.55
Zinc, spot, New York	9.05
Zinc, spot, E. St. Louis	8.70
Silver (Dollars per oz.)	1.34½

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	27.50
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	33.50
Seamless bronze tubing	34.50
Seamless brass tubing	30.50

RARER METALS

Magnesium	lb.	$1.75@1.90
Cadmium	lb.	1.50
Cobalt	lb.	1.50
Platinum	oz.	150.00
Iridium	oz.	250.00
Palladium	oz.	150.00
Mercury	75 lb.	80.00

SCRAP METALS

	Cents per Lb

Brass, casting	10½@10¾
Brass, light	5¾@ 6¾
No. 1 clean brass turnings	8⅛@ 8¾
No. 1 comp. turnings	12 @12¼
Lead, tea	5½@ 5¾
Lead, heavy	6¾@ 7
Zinc, scrap	4¼@ 4½

The Iron and Steel Market

Pittsburgh, February 13, 1920.

The rate of production mentioned last week for January (85 per cent) has fallen off if anything, due to continued transportation difficulties. Deliveries of coke and metal have been even worse last week than previously, bringing some plants to a point where hand-to-mouth conditions exist between stock-pile and furnaces, while more than one stack has been banked over the week end to conserve materials for the ensuing week's operation. In addition to this, the excessively bad weather throughout the Atlantic and New England states has resulted in embargoes at many important points. Notably, the heavy storms in New York during the last week have paralyzed truck haulage in that vicinity and resulted in an embargo on everything for shipment east of Newark. Such a combination of events is discouraging to mills overwhelmed with insistent demands for prompt material; some mills are not getting enough supplies to operate on, and the others with ample reserve stocks, cannot get cars or engines to move the finished product.

Such conditions are food to a bull market. Buyers are more and more insistent for metal; the sky is almost the limit for small lots of prompt tonnage. Quotations are therefore impossible. The Steel Corporation is still holding to the March 21 schedule; its recent statement of unfilled tonnage indicates a booking rate fully 50 per cent above capacity, with orders now in sufficient volume to carry to December. A fortnight ago a rough average of prices being offered to independents would probably approximate what are known as "Jan. 1" prices, those to which the war-time figures were reduced shortly after the armistice. Despite the effort of one of the largest of the independents to maintain this general level, business is being done at $5, $10 and even $25 a ton above the fixed prices for the war period.

PIG IRON AGAIN UP

Pig iron is again up, following a short period of very heavy buying. Foundry is now at least $41, valley, with basic $43 taken for large tonnage and a disposition to charge even more for left-overs. Bessemer is about $42, valley. Southern foundry has been sold in Cincinnati territory during the week at $42, Birmingham, and this price is being quoted by a number of furnaces for the first half, but at least two of the larger interests are still booking for the rest of the year at $40.

The Ferro-Alloy Market

New York, February 13, 1920.

Ferromanganese continues active both in demand and price. One large firm with works in the Pittsburgh district has quoted as high as $170 a gross ton, other quotations varying from $160@$165. Actual sales at these prices are reported heavy and firm. A steady rise to $200 is looked for by men in the New York end of industry.

Spiegeleisen remains firm in price. Demand is rather brisk and a sympathetic rise is looked for soon. The quotation of $55@$60 f.o.b. Pittsburgh is still in force.

There has been slight movement in tungsten, although no actual orders were reported. The cause of this is evidently the desire of buyers to get it at the prevailing low prices. The looked-for settlement of the tariff situation one way or the other will probably send prices rocketing, as tungsten has been at a standstill since the latter part of last year. Present quotations are: Scheelite, 60 per cent WO_3, $10.50; wolframite, $7@$7.50.

Ferrosilicon holds firm on all grades, 50 per cent being $85 a gross ton; 75 per cent, $150, and 10 to 15 per cent, $65@$70, all quotations being f.o.b. Pittsburgh district.

The Chemical and Allied Industrial Markets

New York, February 16, 1920.

The recent storm has seriously tied up the chemical industry. Producers have been handicapped by a still further curtailment in coal supplies and spot trading has been practically at a standstill. Export business, which has been rather heavy on several items, cannot be filled because of shortage of cars for shipping. The willingness on the part of English buyers to do business in this country despite the extremely abnormal rate of exchange gives evidence of the scarcity of supplies in some lines.

GENERAL CHEMICALS

Trading during the past week has been confined mostly to small lots. *Sal ammoniac* remains in the same position, with the English stocks fast decreasing and an upward trend in the domestic material. *Barium chloride* continues active in demand, with stocks rather scarce. The present quotation is $85@$95 per ton, with some producers going as high as $100. *Bleaching powder* is practically off the spot market, with prices firm, varying from 2@3½c. per lb. With the present demand a rise is looked for soon. *Blue vitriol* has been in heavy demand for domestic; while export business has fallen off slightly, present listing is 8¾c. per lb. The export demand on *caustic potash* remains firm, prices are steady and maintain the same level, of 23@32c. per lb., as the previous report. *Soda ash* remains unaffected by the recent drop in exchange, England being willing to meet these adverse conditions in order to obtain the material. This item is unobtainable on spot. The

present quotation is firm at $2.40 per cwt. *Caustic soda* is in the same position as soda ash. Foreign buyers are meeting the American producers' prices in order to obtain material which the extreme coal shortage has cut off.

Coal-Tar Products

The Bureau of Imports, War Trade Board Section, has recently sent out an application form to all dealers in coal-tar products and dyes regarding the importation into this country from Germany of German dyes. The purpose of this application is to restrain the flooding of the domestic market with these colors, thereby running domestic producers out of this industry. In order to obtain the German colors it must be testified to that these dyes are unobtainable in the United States, or if so on terms as to price, quality and delivery as are not considered reasonable. This application is then submitted to the board, which passes or rejects it. It is a question whether this or the tariff regulations is the better plan, but it is the opinion of nearly all that it should be given a trial.

With this question definitely settled a general expansion of plants and increased production is to be expected. *Aniline oil* stands firm, with considerable inquiry during the past week, at 34c. per lb., for forward delivery. *H acid* is unobtainable on spot and difficulty is experienced in getting it on contract, as producers are sold ahead. Prices as high as $1.65 per lb. have been reported. *Benzol* is somewhat easier, with producers offering some material on spot at 25c. per lb. for 90 per cent. *Dimethylaniline* continues scarce. The quotation is nominal, as there is none to be had. Prices as high as $1 per lb. have been reported. There has been no change in the quotation on *toluol*. There seems to be ample stocks of this material, and 28@32c. of last week still holds.

Naval Stores

It is heard on some sides that there is no scarcity in *spirits of turpentine* and that speculation is the cause of the sensational rise in this item to $2.04 per gal. There evidently is ground for holding both opinions. England is still a big buyer despite the high prices and the rate of exchange. The *rosins* are easier, with a noticeable drop in all grades which is caused by a slacking of demand.

Crude Rubber

The crude rubber market remains practically unchanged, but there is a slight undercurrent of firmness inspired by the English and Indian markets. Actual business has been very light, as buyers have shown no inclination to buy even at the comparatively low figures. *Para, up-river fine*, is down to 45@46c. per lb. and the coarse is listed at 33c. per lb. The plantation grades have been extremely quiet with no contract business reported.

Feldspar and Barytes

Feldspar remains unchanged. Manufacturers are reported sold up until end of the year. Difficulties in transportation, cold weather and scarcity of labor are further crippling this commodity. The Government price of $18 still prevails.

Barytes is still scarce. Contracts are not binding, as they may be broken by either party. If the cost of production increases after the contract is made, the producer may raise the price, but the buyer also has the privilege of refusing the goods if the price is too high. Barytes, white floated, $34@$36 per ton; off color, $22@$28 per ton.

Chicago, February 11, 1920.

Pine tar products, which have been under heavy foreign buying pressure for some time, can probably be expected to be a little easier in tone as a result of low exchange, but this reflex is not yet felt in this market.

Plenty of bids are made for goods, but large lots are frequently unobtainable. Short stocks are particularly troublesome as regards *flotation oils* and *fertilizers*, in both of which lines prices remain unchanged at a high level. It is probable that threatened rail labor troubles are causing buyers to proceed slowly also.

Heavy Chemicals: *Alcohol* is the product hardest to obtain, spot stocks of *methyl* being practically exhausted. When obtainable, 95 per cent goes at $1.90@$2 per gal. in small quantities, against a quotation of $1.80 two weeks ago. *Ethyl*, with a nominal quotation of $5.35 a gal. for 190 proof, is very uncertain in delivery. Actual sales of stock on hand have been closed as high as $7.50 in bbl. lots. *Formaldehyde*, which advanced so rapidly last month, is but little easier, current quotation being 45@48c. Small quantities only are available, and demand greatly exceeds offerings. Future orders for formaldehyde are being placed at 25@27c.

Caustic soda has eased off about a quarter of a cent, $4.25 per cwt. in carlots, f.o.b. works, now being quoted for granulated and $3.90@$4 for solid. Export shipments of *bleaching powder* have rendered it short, for immediate delivery, and $3 per cwt. in carloads is the ruling price. *Sodium bichromate* continues to fluctuate, present market being able to absorb all offers at 23@25c. per lb.

No other changes of moment are noted. The increase recently recorded in *roll sulphur* (brimstone) holds good, spot stock in bbl. being quoted at 5c., and carloads from factory at $3.80@$3.90 per cwt. *Acids* seem to have slightly more strength, *sulphuric* 66 deg., being quoted at $22 a ton in cars and *oxalic* at 42c. per lb. in bbl., against prices of $20 and 40c., respectively, two weeks ago. Threatened rail troubles which cause uncertainty in the steel industry tend to prevent much activity in the market for acids.

Coal-Tar Products: Quieter demand for crudes has eased up prices all along the line, and this condition is accentuated by freer offering of supplies. If no further interruption occurs to production or transportation, it is evident that prices will be appreciably lower than those ruling at present. *Benzol* in drums is back to 27c., from an earlier quotation of 33c., and *toluol* is changing hands at 28c. in tanks. *Anilines* are slightly easier, for spots, 34c. being the ruling price on oil and 44c. on salts. Demand seems light on these items, probably on account of the high price.

Benzoic acid now brings, in wholesale quantities, 90c. for U. S. P. and 75c. for technical grade, these items showing reductions of 5c. and 3c., respectively. *Salicylic acid* remains at the former quotation of 44c. for technical and 55c. for U. S. P. As expected, *picric acid* has advanced until it has now reached a price of 25c., which seems reasonable.

Vegetable Oils: Linseed is unchanged in price. There is but little trading. The condition seems to be that, with an Argentine crop of unknown proportions approaching, buyers do not care to invest heavily at present prices, and with flaxseed selling at better than $5, crushers cannot reduce prices. Present Chicago quotation on oil is around $1.75 per gal. in carlots and $1.98 in bbl. *Cocoanut oil* is also weak—probably owing to similar conditions—with miller grade in bbl. being quoted at 19c. in this market. *Soya bean oil* is stronger than the rest of the line, demand remaining fairly strong at 17½c., in sellers' tanks, f.o.b. Coast. Offerings in *corn oil* continue to exceed buyers' requirements, and *crude* is now quoted at 18¾c. in bbl., f.o.b. Chicago, *prime summer yellow* at 23@24c.

Flotation Oils; Naval Stores: Continued high prices have caused a marked decrease in turnover, but the market is holding firm. There has been no change in price recorded anywhere in the line. The one item in which stocks are short is *pine oil*. Spot stocks practically do not exist and dealers are uniformly refusing new business and are taking care of regular customers as well as possible at the old price of $1.50 per gal. in cars for both pure and destructively distilled.

Fertilizers: Buyers seem to feel that prices are too high, and as a result the market has been and is very quiet. Supplies are short, but what little changed hands went at record prices, *ground blood* being offered at from $7.90@$8.10 and *unground blood* at $7.75@$7.85. Similar increase occurred in prices asked for tankage, and but little business resulted. Current quotation for high-grade *ground tankage* is $7.65. Similar conditions prevail in trading in *bone meal*, prices ranging from the last quotation of $44 up to $48 per ton, f.o.b. Chicago, in carlots.

Tannic (tech.)	lb.	.....	.42 – .55
Tartaric, crystals	lb.	.....	.69 – .74
Tungstic, per lb. of WO	lb.	.....	1.20 – 1.40
*Alcohol, Ethyl	gal.	4.80 – 5.50	6.00 – 7.00
*Alcohol, Methyl	gal.	1.50 –	1.52 – 1.57
*Alcohol, denatured, 188 proof	gal.	.....	.76 – .78
*Alcohol, denatured, 190 proof	gal.	.....	.71 – .73
Alum, ammonia lump	lb.	.04½– .05	.05½– .06
Alum, potash lump	lb.	.08 – .08¾	.09 – .09½
Alum, chrome lump	lb.	.15 – .16	.18 – .20
Aluminum sulphate, commercial	lb.	.01¾– .02	.02½– .02½
Aluminum sulphate, iron free	lb.	.02½– .03	.03½– .03½
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.08¾– .10¾	.11 – .12
Ammonia, anhydrous, cylinders (100-150 lb.)	lb.	.33 – .35	.35 – .37
Ammonium carbonate, powder	lb.	.13 – .16½	.17 – .17½
Ammonium chloride, granular (white salammoniac)	lb.	.14 – .15	.16 – .17½
Ammonium chloride, granular (gray salammoniac)	lb.	.13 – .13½	.14 – .14½
Ammonium nitrate	lb.	.22 –	.....
Ammonium sulphate	lb.	.05 –	.06 – .....
Amylacetate	gal.	.....	3.65 – 3.75
Arsenic, oxide, lumps (white arsenic)	lb.	.....	.10½– .11
Arsenic, sulphide, powdered (red arsenic)	lb.	.23 – .24	.....
Barium chloride	ton	85.00 –95.00	100.00 –110.00
Barium dioxide (peroxide)	lb.	.22 –	.24 – .....
Barium nitrate	lb.	.11 – .12	.13 – .14
Barium sulphate (precip.) (blanc fixe)	lb.	.03 – .03½	.03¾– .04
Bleaching powder (see calcium hypochlorite)		.....	.....
Blue vitriol (see copper sulphate)		.....	.....
Borax (see sodium borate)		.....	.....
Brimstone (see sulphur, roll)		.....	.....
Bromine	lb.	.90 – .95	.....
Calcium acetate	cwt.	2.00 – 2.05	2.10 – .....
Calcium carbide	lb.	.....	.04¾ .05
Calcium chloride, fused, lump	ton	20.00 –25.00	30.00 – 40.00
Calcium chloride, granulated	lb.	.01½– .01¾	.02 – .02¼
Calcium hypochlorite (bleaching powder)	cwt.	.....	2.50 – 3.00
Calcium peroxide	lb.	.....	1.50 – 1.70
Calcium phosphate, monobasic	lb.	.....	.75 – .80
Calcium sulphate, pure	lb.	.....	.25 – .30
Carbon bisulphide	lb.	.06 – .08	.09 – .10
Carbon tetrachloride, drums	lb.	..... – .11	.12 – .15½
Carbonyl chloride (phosgene)	lb.	.....	.75 – 1.00
Caustic potash (see potassium hydroxide)		.....	.....
Caustic soda (see sodium hydroxide)		.....	.....
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.08 – .....
Chloroform	lb.	.28 – .29	.30 – .31
Cobalt oxide	lb.	.....	1.50 – 1.55
Copperas (see iron sulphate)		.....	.....
Copper carbonate, green precipitate	lb.	.27 – .28	.29 – .31
Copper cyanide	lb.	.....	.65 – .70
Copper sulphate, crystals	lb.	.08¼– .09	.09 – .09¼
Cream of tartar (see potassium bitartrate)		.....	.....
Epsom salt (see magnesium sulphate)		.....	3.00 – 3.25
Formaldehyde, 40 per cent	lb.	.....	.42 – .52
Glauber's salt (see sodium sulphate)		.....	.....
Glycerine	lb.	.....	.24½– .26
Iodine, resublimed	lb.	.....	4.10 – 4.30
Iron oxide, red	lb.	.....	.03 – .20
Iron sulphate (copperas)	cwt.	1.20 –	1.25 – 1.75
Lead acetate, normal	lb.	.12 – .13	.14 – .23
Lead arsenate (paste)	lb.	.....	.13 – .17
Lead nitrate, crystals	lb.	.....	.70 – .80
Litharge	lb.	.....	.09½– .10½
Lithium carbonate	lb.	.....	1.50 – .....
Magnesium carbonate, technical	lb.	.....	.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	2.15 – 2.63	2.75 – 3.00
Magnesium sulphate, commercial	100 lb.	1.75 –	2.00 – 2.50
Nickel salt, double	lb.	.14 –	.15 – .....
Nickel salt, single	lb.	.16 –	.17 – .....
Phosgene (see carbonyl chloride)		.....	.....
Phosphorus, red	lb.	.....	.60 – .65
Phosphorus, yellow	lb.	.....	.35 – .37
Potassium bichromate	lb.	.32 – .33	.34 – .35
Potassium bitartrate (cream of Tartar)	lb.	.....	.56 – .60
Potassium bromide, granular	lb.	.....	.50 – .65
Potassium carbonate, U. S. P.	lb.	.60	.65 – .70
Potassium carbonate, crude	lb.	.26 – .27	.28 – .30
Potassium chlorate, crystals	lb.	.16 – .20	.21 – .....
Potassium cyanide, 98-99 per cent	lb.	nominal	
Potassium hydroxide (caustic potash)	lb.	.28 – .32	.35 – .42
Potassium iodide	lb.	.....	3.35 – 3.60
Potassium nitrate	lb.	.19 –	.21 – .....
Potassium permanganate	lb.	.....	$0.65 – $0.95
Potassium prussiate, red	lb.	1.00 – 1.05	1.10 – 1.20
Potassium prussiate, yellow	lb.	.....	.40 – .70
Potassium sulphate	ton	$225.00 –	.....
Rochelle salts (see sodium potas. tartrate)		.....	.....
Salammoniac (see ammonium chloride)		.....	.....
Sal soda (see sodium carbonate)		.....	.....
Salt cake (sodium sulphate)	ton	18.00 –21.00	.....
Silver cyanide	oz.	.....	1.25 – .....
Silver nitrate	oz.	.....	.81½– .82¾
Soda ash, light	100 lb.	2.05 –	2.25 – .....
Soda ash, dense	100 lb.	2.25 – 2.50	2.50 – 2.75
Sodium acetate	lb.	.06¾– .07	.07 – .08
Sodium bicarbonate	100 lb.	2.40 –	2.75 – 3.00
Sodium bichromate	lb.	.21½– .22½	.23 – .25
Sodium bisulphate (nitre cake)	cwt.	6.00 – 7.00	8.00 – 10.00
Sodium bisulphite	ton	7.00 – 8.00	8.50 – 9.00
Sodium borate (borax)	lb.	.08½– .08¾	..... – .09
Sodium carbonate (sal soda)	100 lb.	1.40 – 1.55	1.50 – 1.75
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.30 –	.31 – .34
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	.....	4.35 – 4.60
Sodium hyposulphite	lb.	.....	.03¾ .04
Sodium molybdate	lb.	2.50 –	3.25 – .....
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	.15 – .17	..... – .18
Sodium peroxide, powdered	lb.	.....	.30 – .32
Sodium phosphate, dibasic	lb.	.03¾– .04½	.04½– .05
Sodium potassium tartrate (Rochelle salts)	lb.	.40 – .42	.43 – .45½
Sodium prussiate, yellow	lb.	.23 – .29	.30 – .40
Sodium silicate, solution (40 deg.)	lb.	.01¾– .02	.02 – .02¼
Sodium silicate, solution (60 deg.)	lb.	.02¼– .03	.05 – .06
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.15 – 1.50	1.60 – 2.00
Sodium sulphide, crystal, 60–62 per cent (conc)	lb.	.....	.05 – .06
Sodium sulphite, crystals	lb.	.03½–	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 – .....
Sulphur chloride	lb.	.05¾–	.06 – .....
Sulphur, crude	ton	22.00 –	.....
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½–	.46 – .50
Tin oxide	lb.	.50 – .60	.65 – .....
Zinc carbonate, precipitate	lb.	.....	.20 – .....
Zinc chloride, gran	lb.	.13 –	.13½– .15
Zinc cyanide	lb.	.49 –	.50 – .....
Zinc dust	lb.	.11¾– .12½	.13 – .15
Zinc oxide, dry American	lb.	.....	.09½– .12
Zinc sulphate	lb.	.03½– .03¾	.04 – .04½

*Nominal quotations.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.34 —	.42
Aniline oil, drums extra	lb.	.34 —	.45
Aniline salts	lb.	.42 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.05 —	1.25
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.55
Beta naphthol, sublimed	lb.	.65 —	.80
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 —	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.85 —	1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.80 —	1.00
Cresylic acid, 50%, first quality, drums	gal.	.70 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline	lb.	.90 —	1.15
Dinitrobenzol	lb.	.26 —	.37
Dinitro-chlorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine	lb.	.55 —	.65
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3.75 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.80 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	25 —	.45
Para-amido phenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.12 —	.18
Paranitraniline	lb.	1.00 —	1.35
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.15 —	3.00
Paratoluidine	lb.	1.75 —	2.50
Phthalic anhydride	lb.	.60 —	1.00
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 —	.25
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.43 —	.45
Salicylic acid, U. S. P.	lb.	.55 —	.60
Salol	lb.	.90 —	.95

Solvent naphtha, water-white, in drums, 100 gal..	gal.	$0.22 —	$0.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	....
Xylol, commercial, in drums, 100 gal	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42 —	$0.45
Beeswax, refined, yellow	lb.	.47 —	.48
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1	lb.	.80 —	.88
Carnauba, No. 2, regular	lb.	.65 —	.78
Carnauba, No. 3, North Country	lb.	.46 —	.48
Japan	lb.	.18¼ —	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.06 —	.07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.07
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.09¾ —	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.14
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.48
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.60
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl	280 lb.	$18.15	—$18.50
Rosin E-I	280 lb.	18.50	— 18.75
Rosin K-N	280 lb.	19.00	— 21.50
Rosin W. G.-W. W	280 lb.	22.00	— 24.25
Wood rosin, bbl	280 lb.	17.00	— 17.50
Spirits of turpentine	gal.	.....	— 1.97
Wood turpentine, steam dist	gal.	.....	— 1.70
Wood turpentine, dest. dist	gal.	1.64	— ....
Pine tar pitch, bbl	200 lb.	8.25	— 8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	— 14.75
Retort tar, bbl	500 lb.	15.00	— 15.25
Rosin oil, first run	gal.	.....	— .91
Rosin oil, second run	gal.	.93	— .94
Rosin oil, third run	gal.	1.10	— 1.12
Rosin oil, fourth run	gal.	.....	— 1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.44 —	$0.46
Upriver coarse	lb.	.33 —	.35
Upriver caucho ball	lb.	.33½ —	.34½
Plantation—First latex crepe	lb.	.50 —	.54½
Ribbed smoked sheets	lb.	.49 —	.51
Brown crepe, thin, clean	lb.	.48 —	.48½
Amber crepe No. 1	lb.	.53 —	....

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.18 —	$0.19
Castor oil, AA, in bbls	lb.	.21 —	.23
China wood oil, in bbls	lb.	.23¾ —	.24½
Cocoanut oil, Ceylon grade, in bbls	lb.	.21 —	.21¾
Cocoanut oil, Cochin grade, in bbls	lb.	.20¾ —	.23
Corn oil, crude, in bbls	lb.	.19 —	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.19 —	.20
Cottonseed oil, summer yellow	lb.	.22 —	.27
Cottonseed oil, winter yellow	lb.	.24½ —	.25½
Linseed oil, raw, car lots	gal.	1.77 —	1.87
Linseed oil, raw, tank cars	gal.	1.70 —	1.80
Linseed oil, boiled, car lots	gal.	1.75 —	1.80
Olive oil, commercial	gal.	2.50 —	2.60
Palm, Lagos	lb.	.17 —	.18
Palm, bright red	lb.	.16½ —	.17½
Palm, Niger	lb.	.16 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23½ —	.24
Peanut oil, refined, in bbls	lb.	.27 —	.28
Rapeseed oil, refined in bbls	gal.	1.45 —	1.68
Rapeseed oil, blown, in bbls	gal.	1.60 —	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19 —	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.17½ —	.20

FISH

Winter pressed Menhaden	gal.	$1.20 —	....
Yellow bleached Menhaden	gal.	1.23 —	....
White bleached Menhaden	gal.	1.25 —	....
Blown Menhaden	gal.	1.26 —	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00 —	$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.04 —	.05
Blanc fixe, pulp	ton	30.00 —	50.00
Casein	lb.	.16 —	.18
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	.04½ —	.06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar	ton	13.50 —	18.00
Fluor spar, acid grade, lump, f.o.b. mines	net ton	30.00 —	45.00
Fluor spar, acid grade, ground, f.o.b. mines	net ton	50.00 —	52.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00
Graphite, crucible, 85% carbon content	lb.	..... —	.07¾
Graphite, crucible, 86% carbon content	lb.	..... —	.07¾
Graphite, crucible, 87% carbon content	lb.	..... —	.07¾
Graphite, crucible, 88% carbon content	lb.	..... —	.08
Graphite, crucible, 89% carbon content	lb.	..... —	.08¼
Graphite, crucible, 90% carbon content	lb.	..... —	.08¼
Graphite, crucible, 91% carbon content	lb.	..... —	.08¼
Graphite, crucible, 92% carbon content	lb.	..... —	.09
Graphite, crucible, plus 92%		..... —	.12
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, orange, fine	lb.	1.25 —	....
Shellac, orange, superfine	lb.	1.20 —	1.30
Shellac, A. C. garnet	lb.	1.10 —	....
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	16.00 —	60.00
Talc, imported	ton	60.00 —	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	38-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	33-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	45-50 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.50
Ferro-manganese, 70-80% Mn	gross ton	150.00 —	165.00
Spiegeleisen, 16-20% Mn	gross ton	40.00 —	55.00
Ferro-molybdenum, per lb. of Mo	lb.	3.00 —	3.50
Ferro-silicon, 50%	gross ton	85.00 —	95.00
Ferro-silicon, 75%	gross ton	150.00 —	175.00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00

Structural Steel

Mill, Fittsburgh

Beams and channels, 3 to 15-in.	100 lb	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

BANNING—The city has granted a franchise to the Twin Cities Gas Co., recently organized by the Union Natl. Bank of Pasadena, J. M. Berkley, engr., Hollingsworth Bldg., Los Angeles, and others, to reconstruct and enlarge the old gas plant and distributing system. Estimated cost, $27,500. Work will probably be done by day labor.

MERIDIAN—The Alameda Sugar Co., 310 Sansome St., San Francisco, plans to build a sugar refinery, here. Estimated cost, $1,500,000.

SANTA ANA—The Holly Sugar Co. has awarded the contract for the construction of a 2-story, 60x100-ft. sugar factory near here, to Leonard & Peck, 721 H. W. Hellman Bldg., Los Angeles. Estimated cost, $70,000.

VENTURA—The Shell Oil Co. of Ventura plans to build a refinery on its Gosnell lease near here. Estimated cost, $60,000.

Illinois

CHICAGO—The Flexible Steel Lacing Co., 522 South Clinton St., is having plans prepared for the construction of a 1-story, 200x200-ft. factory on Polk St. along the Belt Line R.R. Estimated cost, $200,000. W. G. Carnegie, 189 West Washington St., archt.

CHICAGO—H. C. Miller, archt., 112 West Adams St., will soon award the contract for the construction of a 3-story, 120x140-ft. paper box factory at 1701 Superior St., for the Kroeck Paper Box Co., 220 Institute Pl. Estimated cost, $175,000.

Iowa

DEXTER—H. H. Hough, town clk., will receive bids until Feb. 26 for the construction of a sanitary sewerage system and disposal plant. T. S. DeLay, Creston, consult. engr. Noted Sept. 1.

SCRANTON—L. V. E. Peterson, town clk., will receive bids until March 4, for the construction of a sanitary sewerage system and disposal plant. T. S. DeLay, Creston, consult. engr.

Louisiana

NEW ORLEANS—The Simms Oil Co., Shreveport, plans to construct a 20,000-bbl. refinery above New Orleans on the tidewater terminus, including 280 mi. of 8-in. pipe line from here to Sibley, Claiborne Parish. Estimated cost, $12,000,000. C. B. Denning, pres.

Michigan

ANN ARBOR—The University of Michigan has awarded the contract for the construction of a 6-story hospital on East Anne St., including a 3-story, 56x153-ft. administration building; 51x254-ft. surgical wing, 44x58-ft. demonstration wing and a 35x420-ft. main hospital building with 2 wings, 35x112-ft. and 35x88-ft., to Thompson-Starrett Co., 702 Lincoln Bldg., Detroit. Laboratory equipment will be installed in same. Estimated cost, $1,000,000.

DETROIT—The Bd. of Water Comrs. 242 Jefferson Ave., will soon award the contract for the construction of the substructure for a low lift pumping station. This is the first unit in the construction of a filtration plant to cost over $5,000,000 T. A. Leisen, Waterworks Park, engr.

Nebraska

BROKEN BOW—F. M. Skillman, city clk., has awarded the contract for the construction of a sewerage system, including a disposal plant, to Smith & Chambers, Scotts Bluff. Estimated cost, $167,000. Noted Sept. 14.

New York

BUFFALO—The Dunlap Rubber Co., 1808 B'way, New York City, has awarded the contract for the construction of twelve 1- and 2-story factory buildings, to the Foundation Co., 233 B'way, New York City. Estimated cost, $20,000,000.

BUFFALO—The University of Buffalo, 24 High St., plans to construct a 2-story laboratory addition. Estimated cost, $68,000.

NEW YORK—The Standard Lithographing Co., 1100 Brook Ave., will build a 6-story, 50x118-ft. factory at Brook Ave. and 167th St. Estimated cost, $75,000. Work will be done by day labor.

North Carolina

LEXINGTON—The city rejected all bids for the construction of a water system, including filter house, installation of filter tubs, coagulating basin, etc. G. C. White, Durham, engr. Work will be readvertised.

Ohio

ASHLAND—The city is having plans prepared for the construction of a 1-story, 40x60-ft. superstructure for the filtration plant and is in the market for filter equipment. Estimated cost, $60,000. R. Winthrop Pratt, Hippodrome Bldg., Cleveland, engr.

CLEVELAND—The Buckeye Brass Co., 6410 Hawthorne Ave., is having plans prepared for the construction of a 1-story, 30x110-ft. foundry and a 75x75-ft. furnace room on Ashland Rd. Estimated cost, $50,000. Nathan Carl, secy. Allen Sogg, 319 Hippodrome Bldg., archt.

CLEVELAND—The Cleveland Window Glass & Door Co., 209 Champlain Ave., will build a 1-story, 50x72-ft. mill at 2421 Elm St. Estimated cost, $10,000. Work will be done by day labor.

CLEVELAND — Friedman-Blaw-Farber Co., East 37th St. and Perkins Ave., has awarded the contract for the construction of a 6-story, 57x85x127-ft. addition for the manufacture of knit goods, to the Craig-Curtiss Co., 1031 Guardian Bldg. Estimated cost, $200,000.

COLUMBUS—The Bd. Comrs. Franklin Co., Court House, will receive bids until March 4 for the construction of a 2-story tuberculosis hospital on the Infirmary Grounds. Estimated cost, $125,000. W. H. Tremaine, 602 Chamber of Commerce Bldg., archt.

COLUMBUS—The Ohio Wax Paper & Printing Co., 22nd and Frebis Sts., has awarded the contract for the construction of a 1-story, 111x157-ft. factory on Hartford St., to A. H. Leibrand, 262 Donaldson St. Estimated cost, $45,000.

Oklahoma

PAWHUSKA—The Le Flore Oil & Gas Co., Tulsa, plans to build a refinery, here. Estimated cost, $300,000

TULSA—The Petroleum Club of Tulsa plans to construct a 6-story clubhouse. Estimated cost, $250,000.

TONKAWA—The city plans to improve the waterworks system, including the testing for underground infiltration gallery. Estimated cost, $75,000. Johnson & Benham, Firestone Bldg., Kansas City, Mo., engrs.

Pennsylvania

LOCK HAVEN—The Pensylvania Paper Co. plans to construct a 3-story, 100x300-ft. paper mill on North St., to have a daily capacity of 120 tons of paper. Estimated cost, $3,000,000.

PHILADELPHIA—Franklin & Co., archt. and engr., Crozer Bldg., will soon award the contract for the construction of a 2-story, 28x53-ft. factory building at 10th and Pearl Sts., for the Jarden Lithographing Co., 310 North 11th St. Estimated cost, $20,000.

Washington

SEATTLE—The Western Paper Goods Co., Collins Bldg., has awarded the contract for the construction of a 1-story, 90x103-ft. factory at 1401 Dexter Ave., to Johnson Bros., Hoge Bldg. Estimated cost, $15,000.

Wisconsin

MILWAUKEE—The Central Bd. Purchases, City Hall, will soon award the contract for furnishing 35,000 lb. c.p. anhydrous liquid chlorine for the Water Dept.

WAUKESHA—The Waukesha Cement Tile Co., 102 Main St., plans to build 1-story, 132x136-ft. factory. Estimated cost, $45,000. Work will probably be done by day labor.

Ontario

BRANTFORD — The Dominion Steel Products Co. plans to construct a 1-story, 60x80x100-ft. foundry. Estimated cost, $150,000.

TORONTO—The Canadian Natl. Carbon Co. is having plans prepared for the construction of a factory for the manufacture of oxygen, tanks and oxygen products. Estimated cost, $100,000. Leighton McCarthy, 265 Adelaide St., W., pres.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23 to 26. Headquarters are at the Bellevue-Stratford Hotel.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will have a meeting on Feb. 27, the subject for which is "Electric Furnace Reducing Agents." Another meeting will be held on March 26, the subject of which is "Peace Uses for War Products."

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN INSTITUTE OF MINING AND METTALURGICAL ENGINEERS is holding its spring meeting in New York this week.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE CANADIAN MINING INSTITUTE will hold its annual meeting at the King Edward Hotel, Toronto, March 8 to 10.

THE FARADAY SOCIETY (London) will hold a joint meeting, March 1, with the London Section of the Society of Chemical Industry to receive and discuss a report of Dr. T. Martin Lowry, and E. C. Hemmings on the "Setting of Salts and Other Crystalline Substances." Another meeting will be held March 23, at which there will be a general discussion on "Basic Slag From the Metallurgical and Agricultural Standpoints."

THE INSTITUTE OF METALS will hold its annual general meeting March 11 and 12 at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S. W. 1, London, England.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MATERIAL HANDLING MACHINERY MANUFACTURERS' ASSOCIATION will hold its convention at the Waldorf-Astoria Hotel, New York City, Feb. 26 and 27.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Hoover Heads The A.I.M.E.

THE American Institute of Mining and Metallurgical Engineers is honored in the election of Mr. HOOVER to its presidency for 1920. Leadership in the A.I.M.E. has been on a high plane for many years, but in no recent instance has the incumbent of the office been a man who had attained international reputation in the prime of life. In his forty-sixth year Mr. HOOVER has reached an eminence, not only in the engineering profession but in citizenship, which is achieved by few men at the end of the proverbial threescore years and ten. Through him engineering will receive recognition by the public at large and the engineer's training and kind of thinking will be hailed as a power to be reckoned with in public affairs. It goes without saying that the welfare of the Institute will be enhanced under his leadership.

Government Nitrate Plants Should Be Operated

NITROGEN and its compounds comprise one of the most important chemical topics now before the American people, almost regardless of the avenue through which it may be approached—technical, political, commercial or economic. Technically, the fixation processes are receiving the closest study and attention of our chemical engineers. Politically, the subject acquires importance from the fact that the Government owns fixation plants constructed in war time. Commercially, it may affect our relations with other countries. And as for the economics of the matter, the future independence of nations may be bound up in it. In view of the evident importance of the subject, we shall devote to its consideration an unusual amount of space during the next few months, and authoritative articles will be presented on all its phases.

For a clear preliminary view of the economic situation in the United States we refer the reader to an article by ALFRED H. WHITE, published elsewhere in this issue. It merits the serious consideration of all who are concerned with inorganic fixed nitrogen. The author is connected with none of the conflicting commercial and political interests, and expresses independent views. As a Colonel in the Ordnance Department during the war he was in a position to review all the reports and figures bearing on production and research. He is of the opinion that the Government nitrate plants should be operated, and a careful study of the curves which he presents will show how lightly the operation of these plants will affect commercial enterprise.

As a result of an independent editorial investigation we are in accord with Dr. WHITE regarding the advisability of operating the Government's nitrate plants.

The subject has many phases which will develop later, but for the present it is sufficient to note that there is a demand for the operation of the plants as a matter of preparedness and for the development of fixation processes through research. The agriculturists' demand for inorganic fixed nitrogen is rapidly increasing due to the shortage of organic ammoniates. The construction of a new commercial synthetic ammonia plant by the General Chemical and Solvay interests, themselves in the byproduct coke business, refutes the testimony of Mr. ATWATER of The Barrett Company before the Graham House committee, to the effect that byproduct ammonium sulphate will be sufficient for fertilizer needs. Germany and France are proceeding with the operation of their cyanamide and Haber plants and the English Nitrate Committee has just recommended the immediate erection of both types of plant by the British Government. As for Chilean nitrate, producers of that material are not alarmed at possible competition from Government plants, as the farmer is well educated to the use of Chilean saltpeter. The material is an acceptable fertilizer and the supply reliable.

A great deal of dust has been thrown up in political and commercial circles intending to obscure the clear-cut issues of the whole nitrogen problem. But when this is cleared away we believe that one fact will stand out clearly, namely, that the Government should preserve, operate and develop its plants at Muscle Shoals. The facts on which this policy is based will be presented in subsequent issues of CHEMICAL & METALLURGICAL ENGINEERING.

Increased Demand for Laboratory Facilities

THERE is a constant demand in New York for more laboratories by men who want to prosecute research. The Chemists' Club could dispose of twice the number at its command, and at Columbia University there is a constant appeal for laboratory facilities for private research which cannot be granted. Laboratories are generally crowded.

According to an estimate made by Professor MCKEE, approximately 35 per cent of the country's chemical industries are established within commuting distance of New York, while the second largest complex of applied chemical interests is 5 per cent of the whole, to be found in the neighborhood of Niagara Falls and Buffalo. This may explain why so many chemists engage in research in the metropolitan district. It is open to question whether a large laboratory building with the usual facilities for experimental work and small-scale technical apparatus available for try-outs on a larger scale would be a profitable enterprise. Results are often negative, and very few of our business men are chemically intelligent. The worst feature of applied chemistry

in the United States is that men of other than chemical affairs do not know how to discriminate among chemists. Therefore the incompetent man is often set at research and maintained by far too long a time at his task, while the competent man with good ideas cannot get support, or is halted at the very brink of success.

The demand for laboratories, however, is intense, and there is abundant opportunity for someone or some organization to render a service to industry by supplying the needed facilities. What the country needs is some place where tests and experiments could be performed quickly. Time is usually an important element in the development of an idea, and adequate facilities immediately available would conserve time. Given a laboratory with steam, gas, water, electricity, compressed air, and the requisite apparatus, all probably requiring an investment of at least $5,000 if undertaken privately by each investigator, a competent man would be equipped to carry to early completion a line of research already outlined in his mind. The need of such facilities is imminent. Who can be found with sufficient interest to supply them?

The Ideal of National Industrial Independence

FOR the past five or six years the subject of post-war conditions in the world's leading nations has been, and no doubt will continue for some time to be, a fertile topic for writers on sociology and economics. If one is inclined to question the truth of this assertion, he has only to observe the abundance of this kind of literature published both here and abroad, for there has been a wealth of thought devoted to past and future industrial attainments.

The trend of practically all the post-war economic literature has been toward the ideal status of national industrial independence. This is a logical consequence of the fact that nearly every country was brought to a full realization of what industrial dependence implies, when confronted with the abnormal requirements of war. To a degree more or less acute each and every nation found itself in a position of an improvident man who always prefixes his excuses with an "if." If, for example, for a few decades prior to the war American technologists had not limited their progress to industries based mainly on inorganic chemistry, but had broadened their activities to include industrial organic chemistry, how much more favorable our position would have been when we entered the war! Similarly each of the other nations found it convenient to explain some phase of its dependence with an "if." But national development, like that of the individual, does not always take into consideration the extreme emergency; nor is national independence in industrial matters so simple or easy of attainment as might be imagined. The fact is and always will be that we must take into consideration many ethnological, geographical and economic conditions and their numerous corollaries when trying to appraise the actual or prospective development of industry in the different nations.

No doubt each country that was in the war will strive to attain industrial independence and will tax its abilities to the utmost for realization of this aim, but very few, if any, will succeed. Failure will not be due to any lack of determination or initiative, but solely to the inherent difference in conditions just mentioned.

At first sight we may be greatly encouraged by the progress made in the United States and elsewhere in new industries introduced during the period of war, but we have only to realize how abruptly these developments stopped at the end of the war to see that their rapid growth was made at the expense of other more natural and congenial attainments. Evolution and not revolution is the only basis for progress in a sound industrial program.

In our own United States it is apparent that assimilation and not imitation was the reason why the twentieth-century American people—the so-called melting pot product—withstood practically with immunity the acid test of a great nation. The same thought applies to twentieth-century American industry. The logical post-war prospect for industrial achievement will be determined largely by the spirit of the people and the natural resources of the country. Pre-war times furnished abundant examples of our industrial creative ability. War times showed our relatively rapid progress in new industries hastily produced. It now remains for us in the post-war period to assimilate as thoroughly as possible the hastily introduced industries, especially those based on organic chemistry and the allied sciences. It is only by logical assimilation in harmony with the spirit of the American people and America's natural resources that we can ultimately attain the goal of industrial independence.

An Interpretation of Coke Statistics

THE 1919 coke-production figures of the United States Geological Survey, just announced, suggest some interesting possibilities of future development in the coking of coal in this country. We are told that approximately twenty-five million tons of byproduct coke and nearly twenty million tons of beehive coke were made last year in this country. If we assume the same percentage yield of coke from the coal as during previous years, it means that about thirty-five million tons of coal was used in the byproduct process and thirty-one million tons in beehive ovens.

This is the first time that we have had a larger tonnage of coal used and coke produced in the byproduct process than in beehive ovens, and nationally we can congratulate ourselves on this evidence of real progress. The exact figures show an increase from 46 per cent in 1918 to 56 per cent for 1919 of the total coke production by the byproduct method.

It has been estimated, however, that only about 70 per cent of the possible byproduct oven capacity was utilized in coke production last year. This low percentage was, of course, the result of the coal strike and the steel strike, which greatly aggravated the usual causes of interruptions or low-capacity operation. It is rather interesting to see just what it would have meant if the byproduct ovens could have operated at full capacity. If this had been possible, the coal consumption for the year in this process would have been fully fifty million tons, and the coke production over thirty-five million tons, or 80 per cent of the total coke produced and used last year.

Of course no one believes that 100 per cent capacity will ever be attained in any such industrial process, but 85 to 87 per cent has been demonstrated as entirely feasible, and even 90 to 92 per cent has been attained in certain plants or for certain periods throughout the whole country. If 90 per cent capacity had been

attained, forty-five million tons of coal would have produced about thirty-two million tons of byproduct coke, or over 70 per cent of the actual production for the past year.

Any single industry that uses as much as 12 per cent of our total coal production, as was the case last year in coke manufacture, is worthy of our careful thought at any time; and this particular aspect of the case is especially interesting when we see what a large change in operating conditions and results would have been accomplished if industrial conditions had permitted more nearly normal or even above normal utilization of the available byproduct capacity. It is especially interesting to note that of the sixty-six million tons of coal used in making coke last year, nearly a million tons could have been saved had it been possible to utilize the byproduct process to 90 per cent capacity instead of only 70 per cent and have the beehive operation correspondingly curtailed. Naturally, geographical distribution of the ovens and various company connections make any such change as this rather unlikely; but the large economic significance of such change cannot be safely ignored by anyone concerned in the coal business. It is only a question how long such an economic waste will be allowed to continue without the deserved change in practice.

Dr. Edgar F. Smith Offers His Resignation

THE Provost of the University of Pennsylvania, Dr. EDGAR F. SMITH, has tendered his resignation to the trustees and the trustees have refused to accept it, urging him to continue his labors with them. His years of service have been many, he having begun as instructor in chemistry at the same university in 1876, when he was twenty years of age. He took his bachelor's degree in science when he was eighteen, his doctorate in philosophy at Göttingen at twenty, and since then honorary degrees have been showered upon him in abundance but not beyond his deserts. He is now, at the age of sixty-three, in possession of the great wealth of his faculties, and we hope he may long continue to exercise his beneficent gifts in authority, in teaching, in research and in literature.

He is a great teacher of chemistry. In unusual measure he arouses the intellectual curiosity of his students and thus overcomes the contempt for learning that is an ever-present danger in a number of American colleges and universities. He has also the gift of good fellowship along with the charm of social distinction, of *savoir faire*, of elegance and of grace. These qualities increase his influence among students and make manifest to them, at the same time, the pleasures of scholarship as well as its usefulness.

While keenly alive to his responsibilities, he is utterly neglectful of his rewards in money or property. When the alumni presented him with a house, he declared it was too ostentatious for him and proposed that it be leased to help students in need. He has never tried to get rich; his work in hand was always too interesting to bother about returns from that already done. And he is intensely loyal to his boys.

His contributions in research have been of primary importance. He was a pioneer in electro-analysis and his work in mineral analysis is as great a contribution to mineralogy as it is to chemistry. In a number of respects he established present-day laboratory practice.

The city of Philadelphia is a social institution in itself, and it is replete with old ladies of all ages and sexes. There are illusions of Heaven which obtain there that are even more firmly fixed in the public consciousness than the illusions of the mind in Boston, of smartness in New York, of pounds pressure per square inch in Chicago or of authority in London. According to Philadelphia tradition the incumbent of the office of Provost of the University is *ex officio* a member of its heavenly choir; but here also Dr. SMITH has not failed. He is a very acceptable man.

He has drawn aside the veil of yesterday and introduced to us the shades of our own men of weight in chemistry. Without his delightful monographs and biographies we should have left in the limbo of forgetfulness that splendid galaxy who wrought well for American scholarship in science in the late eighteenth and early nineteen centuries. It is no less than a passion with him to do justice to these men. He has no interest in the minor gossip of the day, and so he is probably still unaware of a curious little side reaction which followed his Life of Robert Hare. In it, so far as we remember, he failed to tell how ROBERT got himself into trouble with certain persons of consequence in his native city and lived for the remainder of his days under somewhat of a social cloud. He was invited to be a member of the committee in charge of an annual assembly ball to which only the elect were bidden. He neither accepted nor declined; he did not even answer the letter! Nothing imaginable could excuse such a fault, and it was never forgiven. His relatives bore the burden, probably with fortitude, but, for aught we know, with bowed heads. He left a single daughter who inherited but little from him and who, after a life in modesty, went the way of all flesh in the maturity of her years.

He had, however, many nephews and nieces. The generations continued and they numbered prominent persons, including a famous bishop, but Uncle ROBERT'S name was seldom mentioned. Whatever his merits they were drowned in the overwhelming flood of his fault in regard to The Assembly. They came Dr. SMITH'S book, which showed him to be truly a great man, while chemistry emerged into fashion with the war. So garrets have been ransacked and now the likeness of Uncle ROBERT hangs in glory and reminders of him have prominent place in the houses of those who willingly forgot him a few years ago.

The only thing that would modify our regret if Dr. SMITH should leave the University of Pennsylvania would be for him to come to New York to live, so that we might see more of him.

Acid Fumes On Riverside Drive

IN RESPONSE to the complaint made by the residents along Riverside Drive, New York City, that the acid fumes from the New Jersey factories are obnoxious, the city chemist has investigated with the result that ten gallons of sulphuric acid are found in every 53,790 gallons of rain water falling in this section.

This seems about the proper amount to give a healthy tang to the air. Chemists will agree that acquaintance with the odor may be cultivated until it becomes delightful to the most effete nostril. One should really learn to know and care for our industrial scents. They are inseparable parts of institutions that make Riverside Drives possible.

Atomic Structure of Metals in Solid Solution

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the article contributed to the issue of your magazine of Nov. 5, Dr. A. L. Feild pointed out the fact that, in the cases of the binary alloys Ag-Au, Ag-Cu, Cu-Ni and (probably) Ni-Cr, the maximal electrical resistance of the solid solutions are those which would be given by the rule of mixtures, if the resistances of the pure metals were assumed to have the values yielded by extrapolation from above the melting points. This relationship, if it be found to obtain for alloys in general, must possess a theoretical significance; but the conclusion which has been drawn appears to be open to serious objections.

This conclusion is essentially the following: In forming solid solutions the component metals do not wholly crystallize, but remain in part amorphous, with the properties of undercooled liquids, as in the intercrystalline cement of the theory of Beilby and Rosenhain; the resistance of the solid solution results additively from those of its amorphous components, but is not a linear function of the composition of the alloy, since the fraction of each metal which remains amorphous is determined by the proportion in which the other metal is present, the amorphous fraction of A increasing with addition of B, and *vice versa*.

The conception accords, at least, qualitatively, with the arched forms shown by resistance-composition curves. But it explains the relation in question only if it be supposed that, for the composition of maximum resistance, which is approximately 50 : 50 in each instance, suppression of crystallization is complete in both metals, so that such an alloy is wholly amorphous. For unless a 50 per cent alloy contains both metals in an entirely amorphous state there is no evident reason why its resistance should be the mean of the resistances which the components might be expected to possess if in a non-crystalline condition.

This seemingly inevitable corollary renders it very difficult to admit the assumption that suppression of crystallization in the formation of solid solutions is accountable for their low conductivities. For the alloys of mineral conductivity possess a crystalline appearance and character as pronounced as that shown by those of any other composition; and moreover, they do not solidify in the manner to be expected of substances which remain amorphous, but instead freeze at a constant temperature, undergoing the discontinuous changes of properties which characterize formation of a new phase.

If, on the other hand, it be assumed that there remains unaltered, during the formation of solid solutions, some property of the liquid metals other than their "amorphousness," the quantitative relation between the observed and the extrapolated values of electrical resistance may be accounted for in a manner exactly analogous to that just discussed, while at the same time the highly improbable implications of this extension of the hypothesis of amorphous metals is avoided. The property retained might, for example, be a purely chemical (electronic) characteristic, and the chemical forces active in the solid solution might be the cause of its cohesion and hardness.

Whatever may be its explanation, the quantitative relation to which Dr. Feild has called attention is exceedingly striking, and data which will show whether it obtains generally are much to be desired.

Contributions by Metallography to L'Art Nouveau

To the Editor of Chemical & Metallurgical Engineering

SIR:—Martin Seyt is right in calling attention to the interesting forms and tones revealed in his microphotographs of metals; but he is certainly wrong in taking the occasion to make public fun of modern art, and his error is in bad taste. What would Mr. Seyt think of an artist who might ridicule metallographic science, though ignorant of it?

What would you think if the editor of some art journal opened his pages to sneering criticisms of reputable scientific achievement?

Modern as well as ancient art can, fortunately, well stand the gibes of those who do not comprehend. The principles upon which they rest endure.

F. B. LEWIS.

Milford, Del.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—Please accept my thanks for copy of the text of Mr. Lewis's communication. What disturbs me far more than his criticism is that he should imagine humor or the making of "public fun of modern art" to be found in my modest contribution. It was an attempt to establish the correlation of Science with Art, more particularly of metallography with painting and sculpture. If Mr. Lewis were familiar with the Dutch language I should recommend to his consideration the much more elaborate efforts in this direction carried out in Holland under the inspiration of my uncle and his collaborator, Adam Seyt and Mohr, of Schiedam.

MARTIN SEYT.

Pure Gum Shellac

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with the greatest interest the excellent article "Pure Gum Shellac," which appeared in your issue of Dec. 10. I am certain the author will allow me to say that in India the well-known letters "T.N." are usually taken as standing for the mark of the firm, well known in its day, which very largely established this grade. The firm in this case was that of Tularam Nataram, which shipped under the initials "T.N."

D. T. CHADWICK,
Indian Trade Commissioner.

Government of India,
London, England.

German Potash Production and Prices

ACCORDING to the German Potash Syndicate the total production of actual potash (K_2O) for 1919 was 946,000 short tons, of which 264,000 tons were sold abroad, the remainder meeting about 41 per cent of home requirements. These figures are given in *Commerce Reports* for Feb. 11, 1920, in conjunction with a report from The Hague dated Jan. 4, 1920, relating to the potash situation in Germany.

New Increase in Potash Prices

The German potash board, with the assent of the Minister of Economics, has announced a further increase in the schedule of prices of potash for domestic consumption. This is the fourth time that the prices have been raised within a year. The new increase amounts to about 45 per cent. The new prices are about six times as high as the prices in force at the time the war began. The mine owners have for some time been making urgent representations that they be allowed to increase prices, on the ground that the constantly increasing cost of operation had rendered production unprofitable. The failure to export any considerable quantity of potash to the United States, where "dollar prices" might have been obtained, is believed to have been one of the considerations which led the board and the Government to authorize the new increase in domestic prices.

Expressed in terms of marks per American unit (which is 1 per cent of actual potash per short ton of material), the new prices of potash for domestic consumption are as shown in the accompanying table:

	Marks per Unit
Crushed carnalite, 9 to 12 per cent actual potash (K_2O)	4.64
Crushed crude salts, 12 to 15 per cent K_2O	5.45
Manure salts, 20 to 22 per cent K_2O	6.73
Manure salts, 30 to 32 per cent K_2O	7.55
Manure salts, 40 to 42 per cent K_2O	8.82
Muriate, 50 to 60 per cent K_2O	10.46
Muriate, 61 per cent K_2O	11.46
Sulphate of potash, 42 per cent K_2O	13.82

Effect on Prices to United States

There is every indication that the syndicate will base its prices for sales to the United States on market conditions in America rather than on the legally regulated maximum prices for consumption in Germany. Germany is so anxious to secure dollar exchange from sales in the United States that the possibility of dumping large amounts of potash in America at low prices seems rather remote at present, especially in view of the fact that present production is far below normal.

Labor Conditions

Since the conclusion of the general wage agreements in July, 1919, labor conditions in the potash mines appear to have been fairly quiet. It is a well-known fact, however, that the productivity of individual laborers is very much diminished. The underground working day is now 7½ hr. instead of 9, as formerly, and the surface working day is 8 hr. in place of 10. One mine owner estimates that the daily individual productivity is now about 50 per cent of what it was before the war; another places the figure at 66 per cent. The factors which are holding back production at present, however, are inadequate housing facilities for workmen at some of the works, and fuel shortage. The latter factor is by far the more important.

In the last week of October it was reported that of the 210 potash works in Germany no less than 120 were lying idle on acocunt of lack of fuel; on Nov. 12 it was reported that 125 were idle.

Outlook of the Potash Industry

The potash syndicate's monopoly over reports from Germany has been left intact in the new legislation providing for the socialization of the industry. Apparently the syndicate is to have a free hand in the matter of dealing with the new situation which has been created by the loss of the Alsatian group of mines. The only present legal limitation over the syndicate's export activities is contained in section 87 of the new potash socialization law of July 19, 1919, which provides that prices for foreign sales may not be below the maximum domestic price.

Under the present circumstance of the heavy demand for German potash in various countries where the mark is at a great discount the syndicate has, of course, no inclination to charge lower prices for export than are charged for domestic sales. It is impossible to predict what kind of a readjustment will take place when the output of the Alsatian mines has increased so that French potash becomes an important factor in world trade, and when the supply of potash approaches the point of meeting the world demand. It does not seem improbable that attempts will then be made to form an international trust which might prove advantageous for the German as well as the French potash industry.

Hoover Awarded Civic Forum Medal

Herbert Hoover was awarded the Civic Forum's Gold Medal of Honor for Distinguished Public Service at a national testimonial in Carnegie Hall, New York, Feb. 18. The presentation was made by the Hon. Charles Evans Hughes, who stated that Mr. Hoover had created for the United States among European nations a reputation which "even the mistakes of diplomacy cannot obscure." Addresses were made by Ray Lyman Wilbur, president of Leland Stanford University; Horace V. Winchell, retiring president of the American Institute of Mining and Metallurgical Engineers; Dr. Aurelia Reinhardt, president of Mills College for Women, and the Hon. Henry Morgenthau, former Ambassador to Turkey. Mr. Hoover responded in a short speech in which he accepted the medal as trustee for the "great American army of volunteer workers and givers of which I was merely the instrument." The award of the medal may be considered a signal honor, the only former recipients being General George W. Goethals, Thomas A. Edison and Dr. Alexander Graham Bell.

Liquidation of Suspended Government Contracts

The Chemical Warfare Service has liquidated 94 per cent of the uncompleted portions of suspended contracts. These suspended contracts aggregated $38,828,000. The settlement payment was $5,197,000. The Nitrate Division of the War Department has liquidated 98 per cent of its suspended contracts, which totaled $9,090,000. The settlement payment was $1,527,000.

Only 48 per cent of the Ordnance Department contracts have been liquidated. These contracts, however, reached the enormous total of $2,040,288,000. To date, settlement payments aggregating $135,040,000 have been paid.

Prominent Chemists Lecture at West Point and Annapolis

In recognition of the increasing importance of chemistry in modern warfare, the Secretaries of War and the Navy requested the American Chemical Society to designate certain of their members to address the students of the Military and Naval Academies on matters relating to chemistry in warfare and chemical engineering.

The lectures are given under the general direction of the professors of chemistry at the two academies and are intended to supplement the regular courses in chemistry. The appointment of the speakers has been in the hands of Dr. William H. Nichols.

The West Point cadets have already heard talks by Dr. Charles L. Reese on the manufacture of explosives; Dr. William H. Walker on "The Manufacturing Problems of Gas Warfare"; Dr. Charles L. Parsons on "Nitrogen Fixation and Its Relation to Warfare"; Dr. Henry Fay on "The Amorphous State in Metals."

At Annapolis, the following chemists have addressed the students: Dr. William H. Nichols on "Sulphuric Acid—the Pig Iron of Chemistry"; Dr. John Johnson on "The Utilization of Research"; Dr. Arthur D. Little on "Natural Resources in Their Relation to Military Supplies"; Dr. Willis R. Whitney on "Industrial Research."

Other important lectures are to be given at both institutions this year.

Grants for Research by the American Association for the Advancement of Science

The American Association for the Advancement of Science has made a grant of $350 to Dr. Gerald L. Wendt, of the University of Chicago, for the investigation of the photochemical reactions of hydrogen and chlorine. Dr. Wendt has been able to show that under the action of alpha rays and in the vacuum discharge tube hydrogen assumes a form very active chemically, which probably has the formula H_3. From a valence point of view the existence—and even more so the properties and the method of formation—of this gas are of great interest. There is some evidence that chlorine is also activated by exposure to light, but the evidence is contradictory. The mechanism of the effect of ultra-violet radiation on chlorine, including the possibility of the existence of an ozone form of chlorine, will be investigated.

The following grants have also been made for research in physics:

To Prof. A. L. Foley, of Indiana University, $150 for experiments on the speed of sound very close to the source. This investigation is in extension of the important and rather remarkable results which Prof. Foley has recently published in the *Physical Review*.

To Prof. Orin Tugman, of the University of Utah, $100 to meet the cost of a monochromatic source of light to be used in finding the change of conductivity in a thin metallic film when exposed to ultra-violet light —a problem which has acquired new importance in view of the rapidly developing electronic theory.

To Prof. E. M. Terry, of the University of Wisconsin, $150 for work on the modulation of radio-energy employed in wireless telephony.

To Prof. F. C. Blake, of the Ohio State University, $100 for aid in prosecution of a study of electric waves and dielectric constants.

New Plan for Educational-Industrial Co-operation

Realizing that technical schools are not serving to a maximum degree the industrial market to which they owe their existence, the Technology Clubs Associated, through their president, have called a meeting at Drexel Institute, in Philadelphia, on March 25, 26, and 27.

Dr. Hollis Godfrey is now president of the combined Technology Clubs Associated. As chairman of the Engineering-Education Section of the Council of National Defense during the period of the war, he foresaw the alarming shortage of trained men. He saw that there was much waste in present technical education and that to eliminate this waste, industry must be called upon to specify exactly what it requires of the graduating engineer.

A number of industries which saw the need for betterment each contributed $2,500 to carry on the study, and besides gave much of the time of their executives. Educators who were also engineers were sent out into the industry. They made a study of manufacturing processes to determine what knowledge was essential if men were to be successful in the various fields. Their findings and the suggestions of the representatives of plants visited were submitted to a board of educational experts who outlined courses and formulated plans to meet the industrial demand with the possible educational supply.

First Plant to Locate at Nitro

The Director of Sales announces that the first commercial industry to locate at Nitro, W. Va., the War Department's "smokeless powder city," will result from the purchase by the Central Foundry & Supply Co. of Columbus, Ohio, of a factory site from the Charleston Industrial Corp. of Charleston, W. Va. The sale has been approved by the Ordnance Salvage Board and the Director of Sales, in accordance with a contract under which the Government sold Nitro to the Charleston Corp. last December.

The "smokeless powder city" site which was selected by the Central Foundry & Supply Co. consisted of five and one-half acres of land and contained such buildings as a sheet metal shop, a brass and iron foundry, a pipe and electric shop, a welding shop and numerous smaller structures. The purchasers will establish a branch plant at Nitro.

Government Needs Chemists and Other Technical Men

The United States Civil Service Commission announces that the Government service is in need of a large number of chemists. During this period of readjustment, technical men are especially needed. Besides chemists, it is stated that there are openings for physicists, ceramic assistants, laboratory assistants and aids; metallurgical, technical and electrical laboratorians, etc. Further information and application blanks may be obtained from the secretary of the U. S. Civil Service Board at Boston, New York, Philadelphia, Atlanta, Cincinnati, Chicago, St. Paul, St. Louis, New Orleans, Seattle or San Francisco, or from the U. S. Civil Service Commission, Washington, D. C.

Disposal of Government Sulphuric Acid

Sulphuric acid to the extent of 1,832,000 lb., declared surplus by the Ordnance Salvage Board, has been sold to the General Chemical Co. of New York.

New York Meeting of the American Institute of Mining Engineers

Report of Annual Meeting at Which Herbert C. Hoover Was Elected President — Institute Approves Joint Conference Committee Report for National Association of Engineers— Simplified Spelling Killed—Report of Technical Sessions

THE annual meeting of the American Institute of Mining and Metallurgical Engineers was held at Institute headquarters in New York, Feb. 16 to 19 inclusive. The business meeting was held Tuesday morning, at which announcement was made of the election of Herbert C. Hoover to be president of the Institute for the ensuing year. Mr. Hoover's presidential address, which was delivered at the banquet, is published elsewhere in this issue.

An effort made by a few enthusiasts to foist simplified spelling on the Institute was decisively defeated, and it is presumed that this matter has finally been killed and that the membership will not again be called upon to waste time in its consideration.

An amendment to the constitution was adopted raising the annual dues from $12 to $15.

The most important matter considered at the meeting on Tuesday morning was the report of the Joint Conference Committee appointed last year to consider, with representatives of the other national engineering societies, a plan to unite all engineers with respect to their civic and public relations. This joint conference report had already been approved by two of the four national societies and is now being considered by the third. The principle involved is the amalgamation of not only the four national societies but of all local and regional societies in the United States into a representative engineering body. It is intended that this body shall be empowered to act for the engineering professions in the United States as far as concerns relations with the public and the Government.

HERBERT C. HOOVER

The report of the Joint Conference Committee was made by Prof. J. W. Richards, who said in part: "The Joint Conference Committee believes that the greatest value of the proposed organization is in the united effort for the service of the nation, from which effort will result the greatest service to the individual. The committee submits the plan in the confident belief that it will be accepted by the four societies; that they will assume the responsibility of leadership, supporting the movement by virtue of their position in the engineering profession. The following movement by local societies is sure to come. Several attempts have been made to organize such a representative body by other agencies than these four engineering societies. There is one society in particular, the American Association of Engineers, which very actively wishes to assume the leadership in this kind of an organization. If the engineering societies do not take this leadership, it will drive it into the hands of those whom we all believe are less qualified to direct it and to lead it. The four national societies can take the initiative and continue their leadership in American engineering by prompt action, or, by inaction, lose the prestige they now hold."

J. Parke Channing, chairman of Engineering Council, urged the adoption of the report, saying: "A thing that has hampered us has been the feeling all over the country that we were not truly representative; that we represented only the four founder societies and the Society for Testing Materials. If we can have what we may term a larger Engineering Council we will better represent the engineering profession and have a better backing."

After further discussion the motion to approve the principles of the report of the Joint Conference Committee was adopted unanimously.

The plan calls for an organization with the following objects:

1. To render the maximum of service to the nation through unity of action.
2. To give the engineers of the country a more potent voice in public affairs.
3. To secure greater recognition of the services of the engineer and to provide for his advancement.
4. To promote *esprit de corps* among the members of the profession.
5. To provide the machinery for prompt and united action on matters affecting the profession, among which are: Licensing and registration of engineers; National Service Committee; National Department of Public Works; conservation of national resources; publicity; classification and compensation of engineers; general employment bureau; engineering education; international affiliation of engineers; industrial relations.

The Smoker

The smoker was a most enjoyable affair. W. L. Saunders presided as ringmaster and made some humorous references to the fact that this was the first dry smoker the Institute had ever attempted to hold. The committee in charge had nevertheless arranged

for some unusual features to offset the lack of the usual refreshment.

First on the program came Major R. Deere, Fellow of the Royal Hypothetical and Hieroglyphical Society and Inspector General of Nurseries for War Babies. The Major announced during the war it became necessary to discover new tin deposits and that a careful search was made in the Province of Ontario, Canada. The selection of a suitable place for prospecting was arrived at mathematically, using the atomic weights of silver which occurred at Cobalt, gold at Porcupine, nickel at Sudbury and copper in Michigan. A special instrument known as the stanniphone was devised to assist in the search of tin. The peculiar characteristic of this device is that when it is manipulated like a divining rod it reproduces the "cry" of tin. The Major showed a geographical map to illustrate just how effectively the stanniphone had functioned. Another feature of the smoker was a modification of the well-known badger fight in which the dupe pulled Mr. Hoover's hat into the ring. The screen was used for films on mining methods at Chuquicamata, Chile, as well as for reproducing some of the unusual ballots on the simplified spelling proposition. Other entertainment was furnished by a quartet and a magician who mystified with tricks and mind reading.

Banquet

The banquet on Tuesday evening was made the occasion for the retiring address of Mr. Winchell and the inaugural speech of Mr. Hoover. Wit and humor characterized the speeches of Toastmaster Lawrence Addicks, who drew repeated rounds of laughter from the audience at the expense of the speakers whom he introduced. The prospect of having a future banquet otherwise than dry was held by him to be improbable in view of the fact that the new president of the Institute spells his name H_2Over.

Retiring President Winchell reviewed the work of the Institute during the past year and emphasized the fact that civic responsibilities must be more largely assumed by engineers. Mr. Hoover's speech, which is printed elsewhere in this issue, practically comprised a statement of governmental policy with regard to railroads, shipping, and industrial relations.

The speeches of the evening were closed by Dr. James F. Kemp, who was created by Mr. Addicks a member of the Order of the Golden Fleece. Dr. Kemp sped the parting and welcomed the coming president in a most pleasing manner.

There was a large attendance of ladies at the Institute meeting and the customary entertainment of luncheons, teas and theater parties was carried out.

Excursion to Bush Terminal

On Thursday the members were taken to the Bush Terminal in Brooklyn, which is the largest port and warehouse development at any harbor in the world. It covers two hundred acres of ground, has thirty miles of railroad track, has modern steamship piers, each over a quarter of a mile long, at which thirty-five steamships can load or unload at the same time.

The plant includes 122 warehouses, fifteen model loft buildings, containing more than 5,000,000 sq.ft. of space, a million-dollar eight-story reinforced concrete service building, equipped with every modern convenience to handle merchandise, and a coal storage plant of scientific type with 1,500,000 cu.ft. of coal storage space.

Metallurgical Sessions

Non-Ferrous Metallurgy

While but three papers were presented at the Institute of Metals division, they were of great interest to those attending, resulting in a very lively discussion of each. Particularly F. L. Antisell's paper on the "Relationship of Physical and Chemical Properties of Copper" was acclaimed as an informative contribution, especially to the user of electrolytic copper.

Mr. Antisell emphasized that it is much simpler to produce from a refining furnace copper shapes which are metallurgically correct than those that are mechanically satisfactory. Evidently extreme care must be taken with metal cast in an open chill-mold if it is to be rolled or drawn into the thinnest sheet or finest wire without exhibiting any surface defects. After briefly discussing the terms "pitch" and "set," and describing the well known action of copper oxide in metal and particularly its detection by fracture and pitch, the author says:

"Unhealthy copper contains slight quantities of gases, such as hydrogen, carbon monoxide, sulphur dioxide, and carbon dioxide. If an attempt is made to remove the excessive oxygen, the copper will spew; that is, a miniature volcanic action will occur in the shape and the copper will be known as overpoled. Copper in this state will be low in electrical conductivity and have a small reduction in area, due to several reasons, particularly the excess of oxygen. These properties can be improved only by subjecting the entire charge to a refining process, which consists of oxidizing the copper, thus removing the reducing gases, and then poling the copper up to a tough pitch. Unhealthy copper may present either a high or a low pitch, but if an attempt is made to raise the low pitch, the copper will spew.

"Reasons for rejecting refined copper on physical examination are: Low pitch; overpoling; cold sets; spewing; shot; fish (slivers of foreign copper, as the fins from the pouring ladle, etc.); holes of several characters, as water holes, shake holes, shrink holes, gas holes, spew holes, general porosity; foreign substances, such as charcoal, bone ash, dirt, etc.; splashes; fins; cracks; large set marks; water bursts; ridges on surface; shapes cast in rough molds; wrong dimensions; and collective defects. By the last term are meant two or more slightly developed defects, one of which would not be a sufficient cause for the rejection of the shape."

Causes for each of these troubles are then mentioned briefly, particularly with reference to their relation to the modern practice of casting in a traveling series of molds. Electrical conductivity, of course, is a most important test for finished copper; this when supplemented by a bending test on a Capp machine will usually give about all the necessary information desirable for acceptances. The author particularly recommended the bending test as simple and very reliable; however, high arsenic will not be detected by it, but this element is quickly noticed in the conductivity measurements.

"A few general laws may be stated for the tough-pitch period, with reference to the relative properties of copper, which are applicable over a short range only:

"1. As the tensile strength increases, the conductivity decreases.

"2. As the oxygen contents increase, the tensile strength increases.

BANQUET OF THE A.I.M.E., NEW YORK, FEB. 17, 1920

"3. As the tensile strength increases, the elongation decreases.

"4. As the oxygen contents increase, the resistance of bending decreases."

Discussion

In the discussion Mr. Caesar emphasized the importance of annealing practice, too often neglected by the manufacturer of rolled or drawn products. For copper, 700 deg. C. is the limit of temperature without endangering the ductility, which heating, by the way, should be done with an oxidizing condition in the furnace.

Prof. A. L. Walker described some early troubles with mechanical casting. For instance, considerable trouble was experienced with otherwise quite satisfactory wire bars having a crack on their under side in the region where the stream of hot metal was poured into the mold. After much study, it appeared that this location stayed liquid longest in the solidifying bar, finally setting considerably later than the ends. Since the intercrystalline cement in copper is very brittle just below the freezing point, the region in question was unable to draw in the solidified ends, and a shrinkage crack resulted, a condition often observed in many metals after slow cooling. The trouble was obviated in this case by moving the pouring stream from end to end of the open mold.

W. R. Webster, however, felt that the above defect was but another confirmation of his growing idea that the standards of performance of copper refiners now are not as high as they were twenty-five years ago. This probably was an unconscious drift, but doubtless was due to the difference between well-done hand work by skillful refiners and carelessly done machine work where quantity was unduly emphasized. For instance, in the old days the Bridgeport brass companies' record charge would be about 40,000 lb., and he felt that the small furnaces then in vogue were much more easily controlled than the huge furnaces now in operation. F. R. Pyne took sharp issue with this idea, saying that since in the old days plates and staybolts were the principal outlet for pure copper products, toughness and strength were the prime considerations. Now, however, copper is made with an eye toward its electrical properties; as a result it is controlled so completely as to its arsenic, silver and oxygen contents that it actually is too pure to suit some manufacturing processes. Aluminum apparently is another whose best properties are had with somewhat impure metal.

Intercrystalline Brittleness

Two papers on intercrystalline brittleness of lead and of copper were presented by H. S. Rawdon in collaboration with S. C. Langdon. It appears that much lead sheathing used to protect aerial and subterranean feederlines on electric systems is subject to a crumbling deterioration, giving spots so weak and brittle that it could be easily crumbled into a gray powder. Each particle when pressed with a pestle appeared quite malleable and, when cut, gave the characteristic color and luster of lead. Microscopic examination of a portion in which the metal was only partly embrittled showed that the method of the corrosive attack is intercrystalline in its nature, and that the action begins on the exposed surface of the sheathing and proceeds inwardly was very evident. A chemical analysis of the material showed that there was no essential difference between the corroded and the uncorroded parts and that the lead contained a considerable amount of tin.

Since the melting point of the granules was within 0.2 deg. C. of the sound portion, it was concluded that allotropy was not present. In fact, specimens of very pure lead were treated in the manner described by previous investigators for the production of the allotropic form of lead. No evidence was obtained to justify the claim that lead may exist in an allotropic state analogous to the well-known gray tin. The forms of lead previously described in the scientific literature as allotropic states appear to be due to an intercrystalline attack by the electrolyte, immersion in which was necessary to bring about the allotropic change. The rate at which the so-called allotropic transformation occurs is largely a function of the purity of the lead and the acidity of the electrolyte in which the metal is immersed.

From these experiments, and others exhibiting the mechanism of etching agent attack, Dr. Rawdon concludes that the difference in solubility of the impurities (which are substantially all insoluble in the solid, and therefore form eutectiferous cementing films) and of the pure lead comprising the interior of the crystal accounts largely for the disintegration of the metal by intercrystalline embrittlement when immersed in a weak acid solution consisting of substances leached out of the surrounding concrete. The greater rate of disintegration of commercial lead, as compared with pure lead, is due to the larger amount of these intercrystalline impurities.

In the short paper on copper, Rawdon and Langdon determine the cause of embrittling when ductile bars are cleaned in molten salt. During this time they had been in contact with iron, thus forming a galvanic cell of which copper was the cathode. Metallic sodium was then deposited from the fused electrolyte, which immediately alloys with the copper. The most striking feature is the selective attack by which the metal at the grain boundaries is acted upon and the action progresses inwardly between the crystals instead of forming an alloy layer upon the outside of uniform thickness. The behavior of a specimen showing under the microscope but a thin penetration by the sodium, when subjected to the bend test illustrates the effect of a relatively thin brittle skin upon the properties of a much larger piece. The structure of the interior of the specimen showed no evidence of brittleness any more than did that of the rod used as an anode, or the rod in its initial state. It may be assumed, therefore, that only a relatively very thin skin has been rendered brittle by the electrolytic action, yet the properties of the entire rod have been very profoundly changed.

Discussion

T. D. Yensen called attention to this latest variety of copper brittleness in comparison to a similar effect of hydrogen, occluded at the cathode or elsewhere. As he has shown with N. B. Pilling, in this case hydrogen enters into the copper very readily, but reacting with the oxide in the eutectic areas, forms water which diffuses outward very slowly.

G. H. Clamer and F. A. Hall also pointed out the very annoying and expensive failures of bearing liners, which had not yet been adequately studied. These liners, which may be either pure lead or lead alloyed with antimony and tin, are turned and soldered to a backing. After more or less service they crack away

at the tinned joint, and if they fall out of a journal without the fact being noticed, hot boxes are sure to result. The same phenomenon gave some trouble with aircraft motors. The connecting rod bearings were bronze shells with babbitt linings. A preliminary study of this indicated intercrystalline fracture, but Mr. HALL was unable to pursue the study to a successful conclusion.

ZAY JEFFRIES pointed out that much brittleness in even purest metal was due to the entirely different physical properties of the crystalline grains and the amorphous cementing material, citing Rosenhain and Archbutt's recent results on season cracking of brass, wherein they show that such is an intercrystalline break due to the amorphous materials' entirely different rate of deformation under applied load than that of the grain metal. A similar effect has been shown by Merica to take place in the β-brass boundaries of α grains. Lead of great purity can be broken at the grain boundaries after long exposure to moderate loads; the amorphous phase apparently is viscous, deforming slowly like pitch, while the crystalline phase is non-viscous but elastic, deforming under load quickly to a definite point. Boiler tubes stressed and at 300 to 400 deg. C. acquire great brittleness for the same reasons: in fact Dr. Jeffries believes that much brittleness can only be explained by a difference of specific properties, amorphous to crystalline phase, usually accentuated at high temperatures and especially evident under slow loadings.

MILLING AND SMELTING

FREDERICK P. DEWEY presented an exhaustive paper on "Volatilization in Assaying" which we hope to publish in full in the near future. Starting from the common excuse of poor results that volatilization is to blame, he discusses the general effect of vaporization in cupellation, the loss through dusting, the relation of vapor pressure and volatility, the condensation of muffle fumes, and then passes on to a review of the literature on volatility of gold, silver and lead, both pure and alloyed and as affected by oxygen in solution, each section of which is amplified by observations from the author's unexcelled practice. In the end he is forced to the conclusion that there is no real evidence that in a properly conducted assay, the loss of either gold or silver by volatilization is sufficient to affect appreciably the result, even when arsenic or antimony may be present.

DISCUSSION

J. W. RICHARDS, in discussion, observed that theoretical deductions from vapor pressure curves were often unsubstantiated in practice simply because losses by "misting" were very important—that is, the true vapor carries with it a cloud of minute globules of liquid metal, whose quantity has no simple relation to the boiling point. The author, however, emphatically disputed the purely theoretical conclusion that all solid metals had a vapor pressure greater than zero.

COAL-PULVERIZING PLANT AT NEVADA CONSOLIDATED SMELTER

A detailed description of a dust-firing system was given by R. E. H. POMEROY in a paper entitled "Coal-Pulverizing Plant at Nevada Consolidated Smelter." The plant itself replaced an oil-storage system and contains many innovations suggested by the smelter staff, and has operated over a year with entire satisfaction and very little repair replacements.

The principal advantages of the system, which influenced this decision, were: (1) Equal safety; no pulverized coal is stored at the furnaces; (2) greater ease of operation, furnace fires being controlled by regulating valves in burner branches, as in gas firing; (3) better organization; all machinery, including pulverized coal feed, is under one roof, and the organization is separate from the furnace department; (4) greater cleanliness; all machinery is under vacuum and the building is automatically ventilated. (5) greater flexibility of application; the coal and air mixture can be piped where needed.

As is perhaps well known, this system works on a closed circuit and involves the transportation of pulverized coal as a suspension in air, the quantity of coal required at any furnace being withdrawn by appropriate connections, and any unconsumed coal, amounting to from 10 to 100 per cent of the supply, may be returned to the grinding plant by a separate main. The paper contains a well-made flow sheet showing each piece of apparatus in its proper location.

DISCUSSION

In discussion, B. F. TILLSON called attention to the fact that certain data, essential to the designer of such piping systems, appeared to be very hard to find. For instance, what is the friction of a stream of air carrying coal? What is the best proportion of air to coal? What is the minimum velocity which will carry, say, 200-mesh coal? Mr. TILLSON also was puzzled to know why flare-backs at the nozzles are not continually occurring. It appears that if all the 2-in. head often used were translated into velocity head, the speed of the combustible mixture would amount to about 8,000 ft. per min., yet the Bureau of Mines states that the minimum velocity of propagation of explosion in coal dust is 200 ft. per sec. and rapidly approaches a velocity ten times as high.

TREATING CONVERTER SLAG

A paper by FREDERICK LAIST and H. J. MAGUIRE on "Reverberatory Furnace for Treating Converter Slag at Anaconda" has already been abstracted in CHEMICAL & METALLURGICAL ENGINEERING, Feb. 4, 1920, p. 231. The chairman, E. P. MATHEWSON, said that this large furnace was constructed with no little trepidation. However, it was structurally excellent, and operated very nearly as predicted after the first few starting troubles had been overcome. The new furnace added far more than its allowable quota to the smoke in the converter building, while some adjustment was necessary before the correct location of the slag inlet was found.

C. G. MAIER emphasized his ideas already developed that in order to recover copper from slags the quantity of contained Fe_3O_4 must be reduced. Otherwise it will oxidize sulphur from the globules of trapped sulphides, forming bubbles of SO_2 gas, which act as a balloon, buoying up the particle.

W. C. SMITH observed that he had examined slags from the Tennessee Copper Co., which substantiated Maier and Van Arsdale's conclusions. Blast furnaces working on green ore showed no magnetite; slag from a matte-concentrating furnace contained but very little magnetite; converter slag, however, was loaded with Fe_3O_4 and overflow from a settler to which molten con-

[1] *Eng. & Mining J.*, May 10, 1919, vol. 107, p. 815; CHEM. & MET. ENG., July 1, 1919, vol. 21, p. 46.

verter slag had been added had nearly as much magnetite as the original converter slag. Mr. Smith had run several series of successive charges of converter slag plus 14 per cent coke into an ordinary blast furnace in regular operation, at the same time sampling the slag at frequent intervals, but no increase in the amount of cementite could be discovered.

E. E. THUM called attention to the diversity of practice in regard to the handling of converter slag at the large Western plants, and pleaded for an analysis of the smelterman's ideas in the light of Maier and Van Arsdale's researches. Many plants cast their converter slag in a more or less expensive manner, using machines of various degrees of excellency, for subsequent resmelting in a blast furnace. Other metallurgists were content to add the slag to a reverberatory furnace; some in the solid state, others insisting that it be poured in with a very considerable drop. It is, in fact, contended that a reverberatory will recover copper from concverter slag if its iron content be low enough, but unfortunately some ore supplies will not allow a close limitation of this element.

MILLING PLANT OF THE ALASKA-GASTINEAU MINING CO.

E. V. DAVELER's paper on the "Milling Plant of the Alaska-Gastineau Mining Co." appears in full on page 361 of this issue. The most noticeable innovation was the use of skip-hoists in place of belt-elevators, and this feature was commented upon in the discussion. W. L. RENICK, a member of the operating staff, stated that these skips were very discouraging at first, requiring two men on each to approach a semblance of operation. A flat cable was used, so that the speed of skip travel rapidly changed even when the driving motor was running uniformly, but unfortunately the blow at the bottom and top stop could not be regulated. This meant trouble with stopping at the correct place, and more trouble with bin gates opening and filling hoist pit with ore. However, as soon as the dash-pot described was hit upon, the problem was solved so satisfactorily that the staff would not think of replacing this automatic equipment with the old-style bucket elevators.

The discussions on Iron and Steel will be presented in this journal for March 3, 1920.

Elimination of Dust Hazard at Niagara Falls Plant

A survey of the chemical and metallurgical plants at Niagara Falls by the United States Public Health Service brought forth the fact that the health of the workers in many of the factories was endangered by the presence of innumerable fine particles of dust in the air. Once breathed into the lungs, such particles are never expelled. Photomicrographs show the tiny particles to be exceedingly sharp and jagged and chemical tests prove them to be practically insoluble.

In all of the factories the laborers were found to be exposed to dangers which would eventually incapacitate them for further work. Fortunately over 60 per cent of the labor in these plants seeks new employment monthly and the result of exposure to such dangers is not as evident as it would be if the workers remained at the same work for longer periods.

As a result of the survey industrial hygiene engineers devised means of removing the dust from the air and minimizing hazards from fumes and poisonous gases. In spite of the fact that the installation of such devices was expensive, factory managements immediately put them into use.

Imports and Exports

The Department of Commerce reports for December, 1919:

German Opinion of Chemical Foundation

In a recent bulletin issued by the Chemical Foundation to its stockholders and licensees, attention is called to an article on "The Chemical Foundation and Its Aims," which appeared in *Die Chemische Industrie*, vol. 42, p. 186, August, 1919. A literal translation of the article is included in the bulletin.

The German critic has been impressed with the idea that the stock of the Foundation is to be as widely distributed as possible, and that each stockholder is to be allowed only two shares of voting stock. He is further impressed with the fact that the patents of the Foundation are open only to those manufacturers who can prove their Americanism as well as to show adequate technical qualifications. He carefully calls attention by the use of italics to the fact that as many of the patents owned by the Foundation are *product* patents, the Foundation should be able to exclude importations *as a matter of course.* In conclusion it is stated that *"the further development of the Chemical Foundation must at any rate be watched very closely in Germany. In truth this company represents the shrewdest militant organization that thus far has been formed abroad against the German chemical industry. Neither legal nor moral scruples concerning the inconsiderate action previously taken against guaranteed private property appear to have occurred to the founders of this company, for whom the principle 'Right or Wrong, My Country' apparently has exclusive prevalence in peace times as well."*

The Engineer in National Affairs

Presidential Address at the Annual Meeting of the American Institute of Mining and Metallurgical Engineers—Outline of a National Policy With Regard to Railroads, Shipping, and Industrial Relations—Need of Engineering Thinking in Government Administration

BY HERBERT C. HOOVER

I HAVE been greatly honored as your unanimous choice for president of this Institute, with which I have been associated during my entire professional life. It is customary for your new president, on these occasions, to make some observation on matters of general interest from the engineer's standpoint.

The profession of engineering in the United States comprises not alone scientific advisers on industry, but is in great majority comprised of the men in administrative positions. In such positions they stand midway between capital and labor. The character of your training and experience leads you to exact and quantitative thought. This basis of training in a great group of Americans furnished a wonderful recruiting ground for service in these last years of tribulation. Many thousands of engineers were called into the Army, the Navy, and civilian service for the Government. Thousands of high offices were discharged by them with credit to the profession and the nation.

Engineers for Efficiency in Government

We have in this country probably one hundred thousand professional engineers. The events of the past few years have greatly stirred their interest in national problems. This has taken practical form in the maintenance of joint committees for discussion of these problems and support to a free advisory bureau in Washington. The engineers want nothing for themselves from Congress. They want efficiency in government, and you contribute to the maintenance of this bureau out of sheer idealism. This organization for consideration of national problems has had many subjects before it, and I propose to touch on some of them this evening.

Interdependence of World Affairs

Even more than ever before is there necessity for your continued interest in this vast complex of problems that must be met by our Government. We are faced with a new orientation of our country to world problems. We face a Europe still at war; still amid social revolutions; some of its peoples still slacking on production; millions starving; and therefore the safety of its civilization is still hanging by a slender thread. Every wind that blows carries to our shores an infection of social disease from this great ferment; every convulsion there has an economic reaction upon our own people. If we needed further proof of the interdependence of the world, we have it today in the practical blockade of our export market. The world is asking us to ratify long-delayed peace in the hope that such confidence will be restored as will enable her to reconstruct her economic life. We are today contemplating maintenance of an enlarged Army and Navy in preparedness for further upheavals in the world and failing to even provide some insurance against war by a league to promote peace.

Some of Today's Problems

Out of the strain of war, weaknesses have become even more evident in our administrative organization, in our legislative machinery. Our Federal Government is still overcentralized, for we have upon the hands of our Government enormous industrial activities which have yet to be demobilized. We are swamped with debt and burdened with taxation. Credit is woefully inflated; speculation and waste are rampant. Our own productivity is decreasing. Our industrial population is crying for remedies for the increasing cost of living and aspiring to better conditions of life and labor. But, beyond all this, great hopes and aspirations are abroad; great moral and social forces have been stimulated by the war and will not be quieted by the ratification of peace. These are but some part of the problems with which we must deal. I have no fear that our people shall not find solutions; but progress is sometimes like the old-fashioned rail fence—some rails are perhaps misshapen, and all look to point the wrong way; but in the end, the fence progresses.

Objections to Government Control

Your committees, jointly with those of other engineering societies, have had before them and expressed their views in many matters concerning the handling of the railways, shipping, the reorganization of the Government engineering work, the national budget, and other practical items.

The war nationalization of railways and shipping are our two greatest problems in Government control awaiting demobilization. There are many fundamental objections to continuation of these experiments in socialism necessitated by the war. They lie chiefly in their destruction of initiative in our people and the dangers of political domination that can grow from governmental operation. Beyond this, the engineers will hold that the successful conduct of great industries is to a transcendent degree dependent upon the personal abilities and character of their employees and staff.

Competition and Efficient Schooling

No scheme of political appointment has ever yet been devised that will replace competition in its selection of ability and character. Both shipping and railways have today the advantage of many skilled personnel, sifted out in the hard school of competition, and even then the Government operation of these enterprises is not proving satisfactory. Therefore, the ultimate inefficiency that would arise from the deadening paralysis of bureaucracy has not yet had full opportunity for development. Already, we can show that no government, under pressure of ever-present

political or sectional interests, can properly conduct the risks of extension and improvement or can be free from local pressure to conduct unwarranted service in industrial enterprise. On the other hand, our people have long since recognized that we cannot turn monopoly over to unrestrained operation for profit or that the human rights of employees can ever be dominated by dividends.

Need of Increased Transportation Facilities

Our business is handicapped on every side by the failure of our transportation facilities to grow with the country. It is useless to talk about increased production to meet an increased standard of living in an increasing population without a greatly increased transport equipment. Moreover, there are very great social problems underlying our transport system. Today their contraction is forcing a congestion of our population around the great cities, with all that these overswollen settlements import. Even such great disturbances as the coal strike have a minor root in our inadequate transportation facilities and their responsibility for intermittent operation of the mines.

We are all hoping that Congress will find a solution to this problem that will be an advanced step toward the combined stimulation of the initiative of the owners, the efficiency of operation, the enlistment of the good will of the employees, and the protection of the public. The problem is easy to state. Its solution is almost overwhelming in complexity. It must develop with experience, step by step—toward a real working partnership of its three elements.

The return of the railways to the owners places predominant private operation upon its final trial. If instant energy, courage, and large vision in the owners should prove lacking in meeting the immediate situation, we will be faced with a reaction that will drive the country to some other form of control. Energetic enlargement of equipment, better service, co-operation with employees, and the least possible advance in rates, together with freedom from political interest, will be the scales upon which the public will weigh these results.

Expansion of Shipping

Important phases of our shipping problem that have come before you should receive wider discussion by the country. As the result of war pressure, we will spend over $2,800,000,000 in the completion of a fleet of nineteen hundred ships, of a total of 11,000,000 tons—nearly one-quarter of the world's cargo shipping. We are proud of this great expansion of our marine, and we wish to retain it under the American flag. Our shipping problem has one large point of departure from the railway problem, for there is no element of natural monopoly. Anyone with a water-tight vehicle can enter upon the seas today, and our Government is now engaged upon the conduct of a nationalized industry in competition with our own people and all the world besides. While in the railways Government inefficiency could be passed on to the consumer, on the seas we will sooner or later find it translated to the national Treasury.

Private vs. Government Shipping Business

Until the present time, there has been a shortage in the world's shipping, but this is being rapidly overtaken, and we shall soon be met with fierce competition of private industry. If the Government continues in the shipping business, we shall be disappointed from the point of view of profits; for we shall be faced with the ability of private enterprise to make profits from the margins of higher cost of Government operation alone. Aside from those losses inherent in bureaucracy and political pressure, there are others special to this case. The largest successfully managed cargo fleet in the world comprises about one hundred and twenty ships, and yet we are attempting to manage nineteen hundred ships at the hands of a Government bureau. In normal times the question of profit or loss in a ship is measured by a few hundred tons of coal wasted, by a little extravagance in repairs, or by four or five days lost on a round trip. Beyond this, private shipping has a free hand to set up such give-and-take relationships with merchants all over the world as will provide sufficient cargo for all legs of a voyage, and these arrangements of co-operation cannot be created by Government employees without charge or danger of favoritism. Lest fault be found, our Government officials are unable to enter upon the detailed higgling in fixing rates required by every cargo and charter. Therefore, they must take refuge in rigid regulations and in fixed rates. In result, their competitors underbid by the smallest margins necessary to get the cargoes. The effect of our large fleet in the world's markets is thus to hold up rates, for so long as this great fleet on one hand holds a fixed rate others will only barely underbid. If we hold up rates, an increasing number of our ships will be idle as the private fleet grows. On the other hand, if we reduce rates we shall be underbid until the Government margin of larger operation cost causes us to lose money.

Problems of American Shipping Industry

We shall yet be faced with the question of demobilizing a considerable part of this fleet into private hands, or frankly acknowledging that we operate it for other reasons than interest on our investment. In this whole problem there are the most difficult considerations requiring the best business thought in the country. In the first instance, our national progress requires that we retain a large fleet under our flag to protect our national commercial expansion overseas. Secondly, we may find it desirable to hold a considerable Government fleet to build up trade routes in expansion of our trade, even at some loss in operation. Thirdly, in order to create this fleet, we have built up an enormous shipbuilding industry. Fifty per cent of the capacity of our shipyards will more than provide any necessary construction for American account. Therefore there is a need of obtaining foreign orders, or the reduction of capacity, or both. I believe, with most engineers, that, with our skill in repetition manufacture, we can compete with any shipbuilders in the world and maintain our American wage standards; but this repetition manufacture implies a constant flow of orders. It would seem highly desirable, in order to maintain the most efficient yards until they can establish themselves firmly in the world's industrial fabric, that the Government should continue to let some ship construction contracts to the lowest bidders, these contracts to supplement private building in such a way as to maintain the continuous operation of the most economical yards and the steady employment of our large number of skilled workers engaged therein.

When we consider giving orders for new ships, we must at the same time consider the sale of ships, as we cannot go on increasing this fleet. When we consider sale, we are confronted with the fact that our present

ships were built under expensive conditions of war, costing from three to four times per ton the pre-war amount, and that already any merchant, subject to the long time of delivery, can build a ship for 75 per cent of their cost. It would at least seem good national policy to sell ships today for the price we can contract for delivery a year or two hence, thus making the Government a reservoir for continuous construction. We could thus stabilize building industry to some degree and also bring the American-owned fleet into better balance, if, as the Government sold three or four emergency-constructed cargo vessels, it gave an order for one ship of a better and faster type. This would make reduction in our shipbuilding steadier and would give the country the type of ships we need.

Engineering Committees Recommend Remedies for Governmental Efficiency

Our joint engineering committees have examined with a great deal of care into organization of and our expenditure on public works and technical services. These committees have consistently and strongly urged the appalling inefficiency in the Government organization of these matters. They report to you that the annual expenditure on such works and services now amounts to over $250,000,000 per annum, and that they are carried out today in nine different governmental departments. They report that there is a great waste by lack of a national policy of co-ordination, in overlapping with different departments, in competition with each other in the purchase of supplies and materials and the support of many engineering staffs.

They recommend the solution that almost every other civilized government has long since adopted, that is, the co-ordination of these measures into one department under which all such undertakings should be conducted and controlled. As a measure practical to our Government, they have advocated that all such bureaus should be transferred to the Interior Department, and all the bureaus not relating to these matters should be transferred from the Interior to other departments. The committee concludes that no properly organized and directed saving in public works can be made until such a regrouping and consolidation is carried out, and that all of the cheese-paring that normally goes on in the honest effort of Congressional committees to control departmental expenditure is but a tithe of that which could be effected if there were some concentration of administration along the lines long since demonstrated as necessary to the success of private business.

National Budget Advocated

Another question of Government organization to which our engineers have given adhesion is in the matter of the national budget. To minds charged with the primary necessity of advance planning, co-ordination, provision of synchronizing parts in organization, the whole notion of our hit-or-miss system is repugnant. A budget system is not the remedy for all administrative ills; it provides a basis of organization that at least does not paralyze administrative efficiency as our system does today. Through it, the co-ordination of expenditure in Government departments, the prevention of waste and overlapping in Government bureaus, the exposure of the pork barrel, and the balancing of the relative importance of different national activities in the allocation of our national income can all be greatly promoted. Legislation would also be expedited. No budget that does not cover all Government expenditure is worth enactment. Furthermore, without such reorganization as the grouping of construction departments, the proper formulation of a budget would be hopeless. The budget system in some form is so universal in civilized governments and in competently conducted business enterprise, and has been adopted in so many of our States, that its absence in our Federal Government is most extraordinary. It is, however, but a further testimony that it is always a far cry of our citizens from the efficiency in their business to interest in the efficiency of their Government.

Problem of Relationship Between Employer and Employee

Another great national problem to which every engineer in the United States is giving earnest thought, and with which he comes in daily contact, is that of the relationship of employer and employee in industry. In this, as in many other national problems today, we are faced with a realization that the science of economics has altered from a science of wealth to a science of human relationships to wealth. We have gone on for many years throwing the greatest of our ingenuity and ability into the improvement of processes and tools of production. We have until recently greatly neglected the human factor that is so large an element in our very productivity. The development of vast repetition in the process of industry has deadened the sense of craftsmanship, and the great extension of industry has divorced the employer and his employee from that contact that carried responsibility for the human problem. This neglect of the human factor has accumulated much of the discontent and unrest throughout our great industrial population and has reacted in a decrease of production. Yet our very standards of living are dependent on a maximum productivity up to the necessities of our population.

Another economic result is, or will be yet, a repercussion upon the fundamental industry of the United States, that is, agriculture. For the farmer will be unable to maintain his production in the face of a constant increase in the cost of his supplies and labor through shrinkage in productivity in other industries. The penalty of this disparity of effort comes mainly out of the farmer's own earnings.

Collective Bargaining and Sanctity of Contracts the Remedy

I am daily impressed with the fact that there is but one way out, and that is to again re-establish, through organized representation, that personal co-operation between employer and employee in production that was a binding force when our industries were smaller of unit and of less specialization. Through this, the sense of craftsmanship and the interest in production can be re-created and the proper establishment of conditions of labor and its participation in a more skilled administration can be worked out. The attitude of refusal to participate in collective bargaining with representatives of the employees' own choosing is the negation of this bridge to better relationship. On the other hand, a complete sense of obligation to bargains entered upon is fundamental to the process itself.

Employee and Employer Have Common Ground

The interests of employee and employer are not necessarily antagonistic; they have a great common

ground of mutuality, and if we could secure emphasis upon these common interests we would greatly mitigate conflict. Our Government can stimulate these forces, but the new relationship of employer and employee must be a matter of deliberate organization within industry itself. I am convinced that the vast majority of American labor fundamentally wishes to co-operate in production and that basis of good will can be organized and the vitality of production re-created.

Intermittency of Employment Great Loss to the Community

Many of the questions of this industrial relationship involve large engineering problems, as an instance of which I know of no better example than the issue you plan for discussion tomorrow in connection with the soft-coal industry. Broadly, here is an industry functioning badly from an engineering and consequently from an economic and human standpoint. Owing to the intermittency of production, seasonal and local, this industry has been equipped to a peak load of 25 or 30 per cent over the average load. It has been provided with a 25 or 30 per cent larger labor complement than it would require if continuous operation could be brought about. I hope your discussion will throw some light on the possibilities of remedy. There lies in this intermittency not only a long train of human misery through intermittent employment, but the economic loss to the community of over a hundred thousand workers who could be applied to other production, and the cost of coal could be decreased to the consumer. This intermittency lies at the root of the last strike in the attempt of the employees to secure an equal division among themselves of this partial employment at a wage that could meet their view of a living return on full employment.

These are but few of the problems that confront us. But in the formulating of measures of solution, we need a constant adherence to a national ideal and our own social philosophy.

Radicalism and Reaction and Their Influence on the Solution of Economic Problems

In the discussion of these ideals and this social philosophy, we hear much of radicalism and of reaction. They are, in fact, not an academic state of mind but realize into real groups and real forces influencing the solution of economic problems in this community. In their present-day practical aspects, they represent on the one hand roughly various degrees of exponents of socialism, who would directly or indirectly undermine the principle of private property and personal initiative, and, on the other hand, those exponents who in various degrees desire to dominate the community for profit and privilege. They both represent attempts to introduce or preserve class privilege, either a moneyed or a bureaucratic aristocracy. We have, however, in American democracy, an ideal and a social philosophy that sympathize neither with radicalism nor reaction as they are manifested today.

American Democracy Has Stood the Test

For generations the American people have been steadily developing a social philosophy as part of their own democracy—and in these ideals it differs from all other democracies. This philosophy has stood this period of test in the fire of common sense; it is, in substance, that there should be an equality of opportunity—an equal chance—to every citizen. This view that every individual should, within his lifetime, not be handicapped in securing that particular niche in the community to which his abilities and character entitle him, is itself the negation of class. Human beings are not equal in these qualities. But a society that is based upon a constant flux of individuals in the community, upon the basis of ability and character, is a moving, virile mass; it is not a stratification of classes. Its inspiration is individual initiative. Its stimulus is competition. Its safeguard is education. Its greatest mentor is free speech and voluntary organization for public good. Its expression in legislation is the common sense and common will of the majority. It is the essence of this democracy that progress of the mass must arise from progress of the individual. It does not permit the presence in the community of those who would not give full meed of service.

American Conception

Its conception of the State is one that, representative of all the citizens, will in the region of economic activities apply itself mainly to the stimulation of knowledge, the undertaking only of works beyond the initiative of the individual or group, the prevention of economic domination of the few over the many, and the least entrance into commerce that Government functions necessitate.

The method and measures by which we solve this accumulation of great problems will depend upon which of these three conceptions will reach the ascendancy among our people.

Unlawful Radicalism Less Dangerous Than Reaction

If we cling to our national ideals it will mean the final isolation and the political abandonment of the minor groups who hope for domination of the Government, either by "interests" or by radical social theories through the control of our political machinery. I sometimes feel that lawful radicalism in politics is less dangerous than reaction, for radicalism is blatant and displays itself in the open. Unlawful radicalism can be handled by the police. Reaction too often fools the people through subtle channels of obstruction and progressive platitudes. There is little danger of radicalism ever controlling a country with so large a farmer population, except in one contingency. That contingency is from a reflex of continued attempt to control this country by the "interests" and other forms of our domestic reactionaries.

U. S. Must First Solve Its Own Problems if It Is to Contribute to Civilization's Advance

The mighty upheaval following the World War has created turmoil and confusion in our own country no less than in all other lands. If America is to contribute to the advance of civilization, it must first solve its own problems, must first secure and maintain its own strength. The kind of problems that present themselves are more predominantly economic—national as well as international—than at any period in our history. They require quantitative and prospective thinking and a sense of organization.

These are the sort of problems that your profession deals with as its daily toil. You have an obligation to continue the fine service you have initiated and to give it your united skill.

Theoretical Study of Nitrogen Fixation by the Electric Arc—II

Chemical Dynamics of the Nitrogen-Oxygen Reactions at the Temperature of the Arc and During Cooling—Effect of the Rate of Cooling Upon the Dissociation of NO—Cooling Curves*

By CHARLES P. STEINMETZ

If THE gas mixture of N_2, O_2, and NO, of concentration a_0 produced by a temperature T_0, is very slowly cooled, during falling temperature the NO concentration will fall so as to have at every temperature T the corresponding equilibrium concentration a, and as a greatly decreases with decreasing temperature, very little NO will be left in the cold gas mixture. If, however, the gas mixture is cooled very rapidly, from the temperature T_0 to the temperature T_1, at which the reaction velocity has become so slow that NO is practically stable, a greater or lesser part of the high concentration a_0, corresponding to the high temperature T_0, will be saved. The quicker the cooling the more will be saved.

The first problem then is to determine that cooling curve, that is, that rate of cooling at which with decreasing temperature the NO concentration still reaches the temperature equilibrium at each temperature; a materially more rapid cooling would be required to save a great part of the NO produced at high temperature.

Mathematically, however, the problem cannot be put in this form, as the reaction curves are exponentials, and the equilibrium concentration at each temperature is reached theoretically only after infinite time.

The problem thus must be put in the form to determine the cooling curve, that is, the rate of temperature decrease, by which the NO concentration a at each temperature exceeds the equilibrium concentration by a small constant value x. That is, to determine the cooling rate $\frac{dT}{dt}$, by which the NO concentration at each temperature T is $a + x$, where a is the equilibrium concentration corresponding to the temperature T, and x a small constant quantity.

Concentration of NO in Air

The equilibrium concentration of NO is given by equation (13):

$$C = \frac{a^2}{\left(n - \frac{a}{2}\right)\left(o - \frac{a}{2}\right)} \qquad (43)$$

where: a = concentration of NO,
n = total or initial N_2 concentration, = 0.777 in air,
o = total or initial O_2 concentration, = 0.210 in air,

and C is the equilibrium constant, which is given as function of the temperature T by van't Hoff's equation:

$$\frac{d \log_e C}{dT} = -\frac{Q}{RT} \qquad (15)$$

Substituting (43) into (15) gives:

$$\frac{d}{dT}\left[\log_e a^2 - \log_e\left(n - \frac{a}{2}\right) - \log_e\left(o - \frac{a}{2}\right)\right] = -\frac{Q}{RT}$$

and expanded:

$$\frac{da}{dT}\left(\frac{2}{a} - \frac{1}{2n - a} - \frac{1}{2o - a}\right) = -\frac{Q}{RT}$$

thus:

$$\frac{da}{dT} = \frac{-Q}{RT^2\left(\frac{2}{a} - \frac{1}{2n - a} - \frac{1}{2o - a}\right)}$$

$$= \frac{21{,}600}{T^2\left(\frac{2}{a} + \frac{1}{1.554 - a} + \frac{1}{0.42 - a}\right)} \qquad (44)$$

Values of the rate of change of the NO concentration a, with the temperature T: $\frac{da}{dT}$ are given in Table IV, from 800 to 4200 deg. abs., and plotted in Fig. 2, together with the values of a.

Lag in Dissociation

If at constant temperature T, the NO concentration exceeds the equilibrium value a by a small amount x,

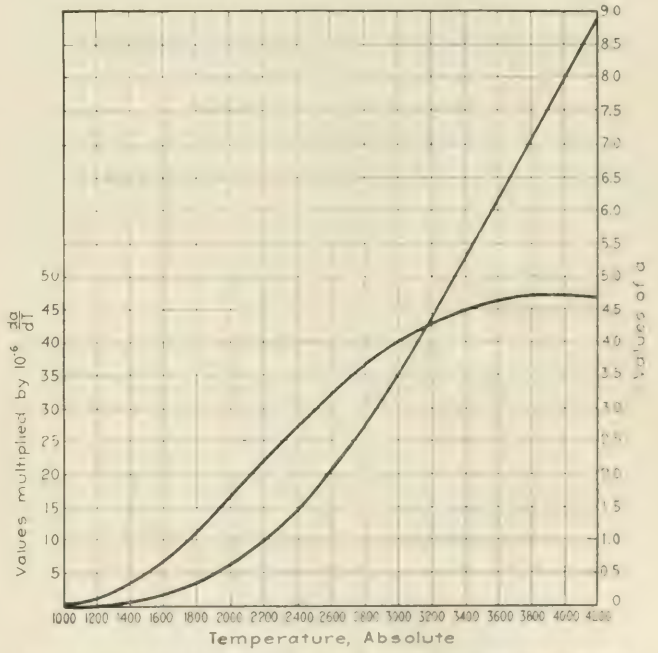

FIG. 2. THERMAL EQUILIBRIUM—NO CONCENTRATION IN AIR

that is, $a + x$, the rate of dissociation is given by equation (26) as:

$$r = \frac{dx}{dt} = c_1(a - x)^2 - c\left(n - \frac{a}{2} - \frac{x}{2}\right)\left(o - \frac{a}{2} - \frac{x}{2}\right) \qquad (45)$$

*For Part I see CHEM. & MET. ENG., vol. 22, No. 7, Feb. 18, 1920, pp. 299-304.

where c_1 and c_2 are the velocity constants given in Table I, as functions of the temperature T.

Expanding (45) and substituting the equilibrium conditions:

$$c_2 a^2 - c_1\left(n - \frac{a}{2}\right)\left(o - \frac{a}{2}\right) = 0$$

gives:

$$v = \frac{dx}{dt} = x\left[2a\left(c_2 - \frac{c_1}{4}\right) + \frac{c_1}{2}(n + o)\right] \qquad (46)$$

or, as c_1 is small compared with c_2:

$$v = \frac{dx}{dt} = x[2ac_2 + \frac{c_1}{2}(n + o)]$$
$$= x(2ac_2 + 0.493c_1) \qquad (47)$$

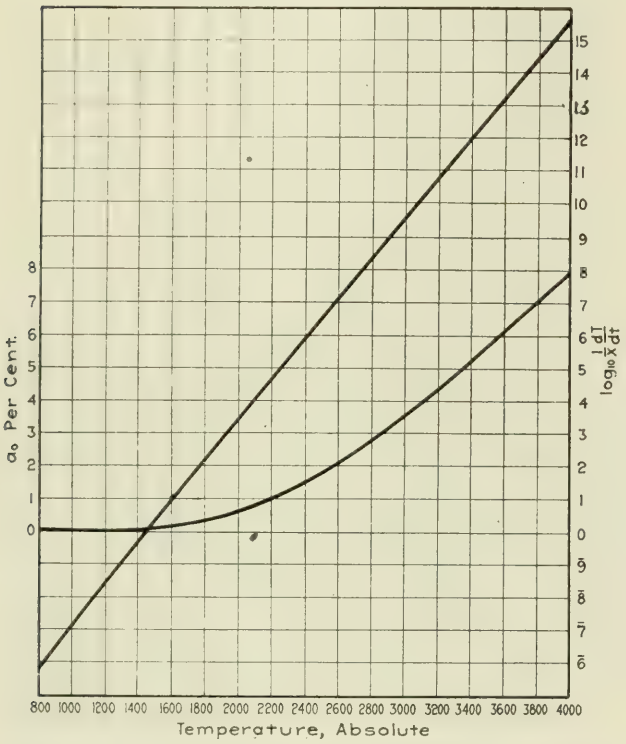

FIG. 3. COOLING CURVES

As the second term in equation (47) is small compared with the first term, this equation can be approximated by:

$$v = \frac{dx}{dt} = 2xac_2 \qquad (48)$$

Values of

$$\frac{1}{x}\frac{dx}{dt} = 2ac_2 - 0.493c_1 \qquad (49)$$

for air, are given in Table IV, and values of:

$$\log_{10} -\frac{1}{x}\frac{dx}{dt}$$

are plotted in Fig. 3 with T as abscissæ, in Fig. 4 with $\log_{10}T$ as abscissæ.

From (44) follows, by integration:

$$x = x_o e^{-(2ac_2 - 0.493c_1)t} \qquad (50)$$

Cooling Curves

If the temperature T of the gas mixture falls with the time t at such a rate

$$\frac{dT}{dt} = f_o(T) \qquad (51)$$

that the change in concentration by dissociation, $\frac{dx}{dt}$, by equation (51), equals the change of equilibrium concentration with the temperature, $\frac{da}{dT}$, then at the decrease of temperature with the time, the decreasing concentration of NO remains by a constant value x above the equilibrium concentration a corresponding to the respective time. That is, on such cooling curve, the NO concentration lags by the constant value x above the falling equilibrium concentration.

The condition herefor obviously is:

$$\frac{dx}{dt} = \frac{da}{dT} \times \frac{dT}{dt} \qquad (52)$$

Thus:

$$\frac{dT}{dt} = f_o(T) = \frac{dx}{dt} \div \frac{da}{dT} \qquad (53)$$

is the equation of the cooling curve giving a constant excess x above the temperature equilibrium values a.

Substituting (46) and (44) into (53), and expanding, gives:

$$\frac{dT}{dt} = -\frac{xRT^2}{Q}[2a\left(c_2 + \frac{c_1}{4}\right) + \frac{c_1}{2}(n + o)]\left(\frac{2}{a} + \frac{1}{2n - a} + \frac{1}{2o - a}\right) = \frac{xT^2}{21{,}600}(2ac_2 + 0.493\,c_1)\left(\frac{2}{a} + \frac{1}{1.554 - a} + \frac{1}{0.42 - a}\right) \qquad (54)$$

Values of $\frac{1}{x}\frac{dT}{dt}$, that is, the cooling curves giving constant excess concentration x, are calculated in Table IV.

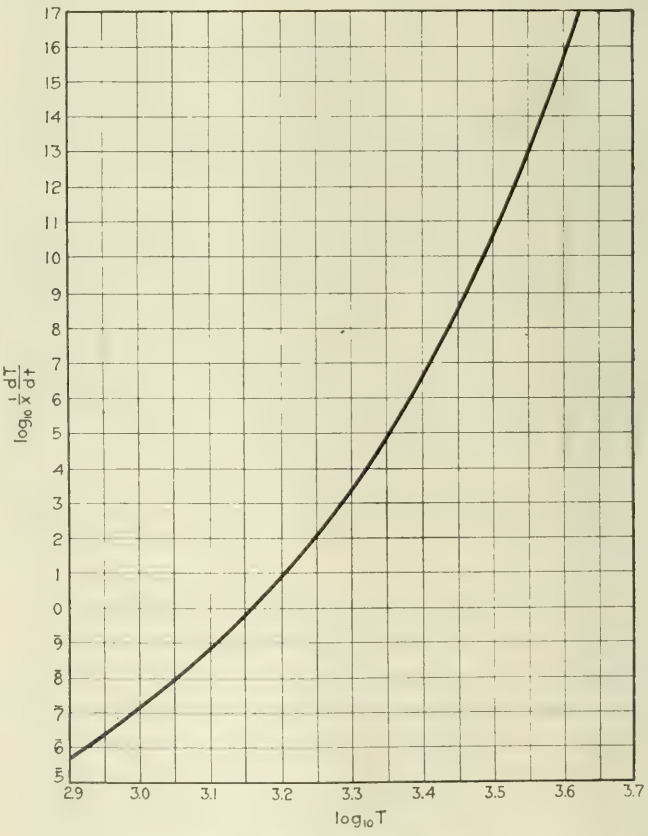

FIG. 4. COOLING CURVES

Inversely now, if a cooling function is given, as for instance, cooling by the radiation law

$$\frac{dT}{dt} = f(T) = bT^4 \qquad (55)$$

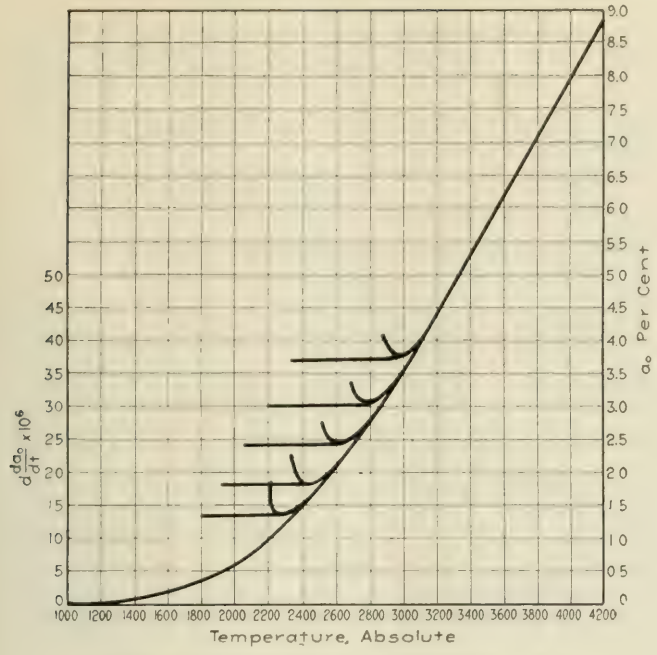

FIG. 5. COOLING BY RADIATION LAW

or cooling by heat conduction, at a rate proportional to the temperature:

$$\frac{dT}{dt} = f(T) = bT \qquad (56)$$

or cooling at a constant rate, as for instance, by an air blast mixing cold air with the gases:

$$\frac{dT}{dt} = f(T) - b \qquad (57)$$

then, by substituting the values of the cooling rate, (55) to (57), etc., into equation (54), the value x is found, that is, for each temperature T, the value x of the NO concentration, by which it exceeds the equilibrium concentration a of this temperature. Provided, however, that x is small compared with a.

This can conveniently be done by plotting the equation (54) in the form:

$$\frac{1}{x}\frac{dT}{dt} = \frac{T^2}{21{,}600}(2ac_2 - 0.493c_1)\left(\frac{2}{a} - \frac{1}{1.554\ a} - \frac{1}{0.42\ a}\right) \qquad (58)$$

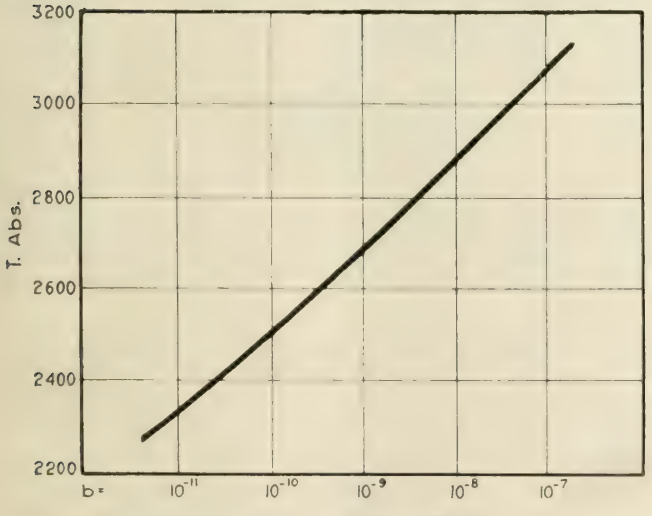

FIG. 6a. COOLING BY RADIATION LAW

with T as abscissæ, this curve being independent of x, and then plotting, of the actual cooling curve $f(T)$, the values $\frac{1}{x}\ f\ (T)$ for various values of x. The points of

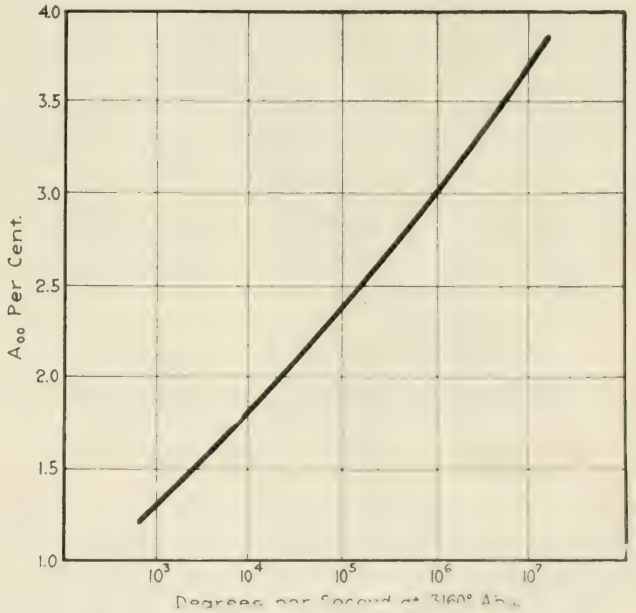

FIG. 6b. COOLING BY RADIATION LAW

intersection with (58) give the temperatures T, at which the excess concentration x exists, and herefrom then a new concentration curve can be plotted, with $a + x$ as ordinates, giving the change of concentration with the temperature, when the temperature decreases by the chosen cooling law $\frac{dT}{dt} = f(T)$.

Cooling by Radiation

The radiation law

$$\frac{dT}{dt} = bT^4 \qquad (59)$$

gives: $$\log_{10} \frac{dT}{dt} = 4 \log_{10} T + \log_{10} b \qquad (60)$$

At: $T = 3160$ deg. abs., $b = 10^{-7}\ 10^{-8}\ 10^{-9}\ 10^{-10}\ 10^{-11}$ gives a cooling rate, per millisecond of:

10,000 1000 100 10 1 deg. C.

If then x is constant, it follows, from (42):

$$\log_{10} \frac{1}{x}\frac{dT}{dt} = 4 \log_{10} T + \log_{10} b - \log_{10} x \qquad (61)$$

a linear equation in $\log_{10} \frac{1}{x}\frac{dT}{dt}$ and $\log_{10} T$.

Plotting then from Table IV, $\log_{10} \frac{1}{x}\frac{dT}{dx}$ as function of $\log_{10} T$, in Fig. 4, as the dissociation function of NO, and taking the points of intersection of this curve with the straight lines (61) corresponding to various values of x, gives $\log_{10} T_0$ and T_0, the critical temperatures, at which in cooling by the law (59) the concentration exceeds the equilibrium value a_0 of temperature T_0, by the value x.

Herefrom then follows the concentration $a_0 + x$ of the cooling curve (59).

Table V gives, for various values of b and of x, the values of T_0, a_0 and $a_0 + x$.

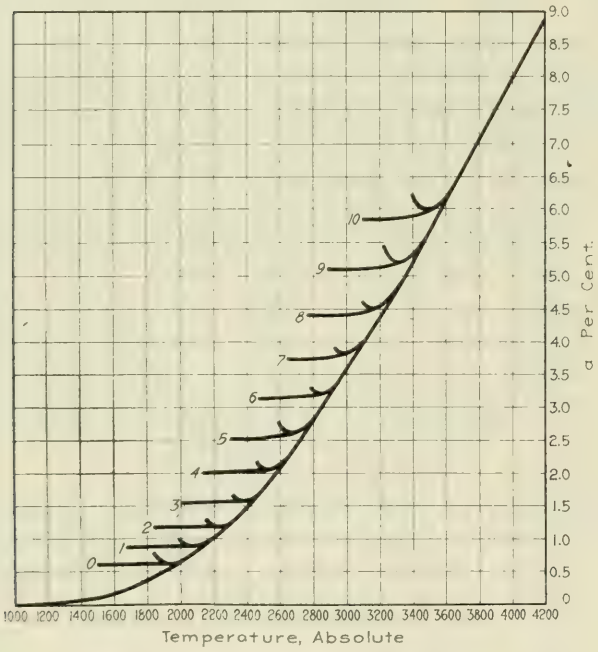

FIG. 7. CONSTANT RATE OF COOLING

a_0 is taken from the plot of a_0 against T, in Fig. 5, and $a_0 + x$ plotted on the same curve sheet, giving an estimate of the final values of concentrations of NO in air.

These are plotted, with b as abscissæ, in Fig. 6, and recorded in Table VI, together with the temperature T_3', at which the minimum of the $a_0 + x$ curve is reached, and the temperature T_{00}, at which the final value of NO concentration, a_{00}, would be the equilibrium values, and the temperature T, at which $x = 0.1$.

Cooling at Constant Rate

Cooling by mixing the arc gases with cold air, as is usually done in arc furnaces, may probably be best approximated by cooling at constant rate, at least within the initial range.

A temperature gradient at the arc surface of 1000 deg. C. per cm. appears reasonable, and even several times as high gradients may be expected in quickly moving arcs. Assuming an air velocity of 100 m. per sec., which is moderate, would give a cooling rate of 10^7 deg. per sec.

Thus, in cooling at uniform rate, by the cooling law

$$\frac{dT}{dt} = -b \qquad (62)$$

$T_{00} =$	3530	3360	3210	3045	2890	2725	2580	2415	2270	2130	2010
$T^1 =$	3470	3300	3170	3000	2850	2670	2530	2380	2210	2070	1950
$T =$	3565	3400	3215	3070	2895	2735	2570	2410	2250	2085	1925

the range of b from 10^{10} to 1 would give the entire range from the lowest cooling rate, up to and beyond the highest feasible rate.

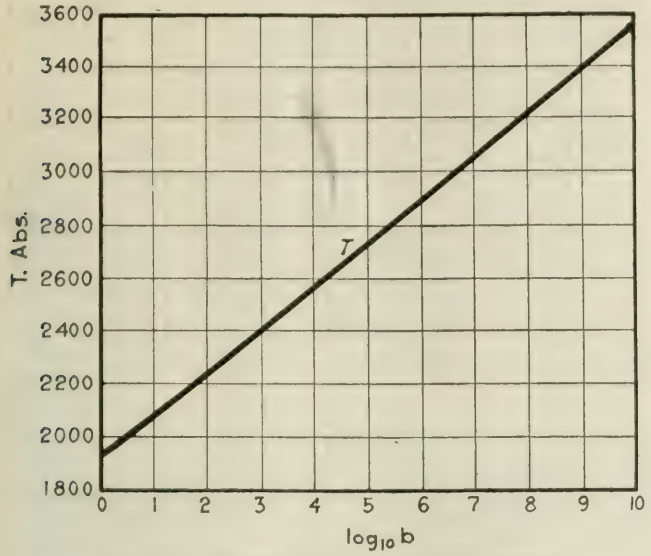

FIG. 8a. CONSTANT RATE OF COOLING

From (62) follows:

$$\log_{10} -\frac{1}{x}\frac{dT}{dt} = \log_{10} b - \log_{10} x \qquad (63)$$

For each value of the cooling constant b, and for the various values of x, the values of $\log_{10} -\frac{1}{x}\frac{dT}{dt}$ thus are found by equation (63), and for these values from Fig. 3 the corresponding values of time T_o are taken and recorded in Table VII, together with the values of a_o, corresponding to T_o, and the values of $a_o + x$. These are plotted in Fig. 7.

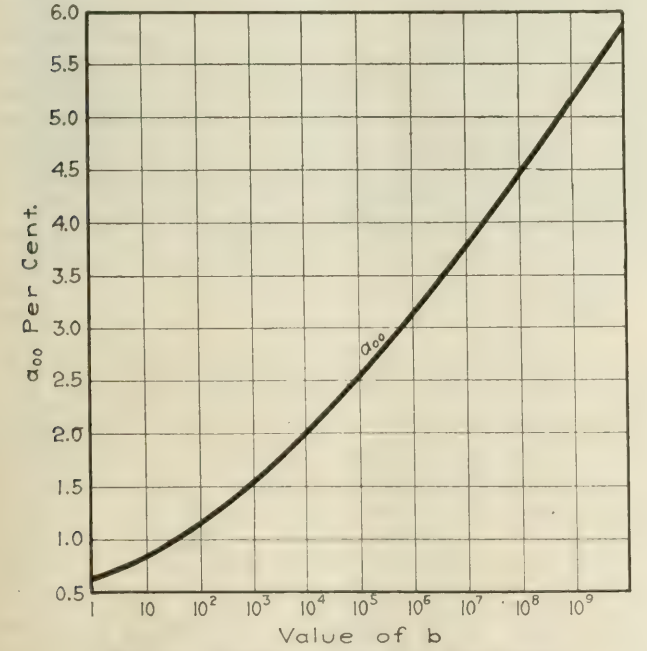

FIG. 8b. CONSTANT RATE OF COOLING

Here again, as in Fig. 5, the curves of $a_o + x$ become an approximation only at the minimum values, and inaccurate at temperatures below the minimum values, due to the assumption that x is small compared to a_o ceasing to apply. The actual curve and the final limiting value a_{oo} of $a_o + x$ thus are estimated and recorded in the last column of Table VII. These are plotted, with b as abscissa, in Fig. 8, and Table VIII gives, for various values of b, the final concentration a_{oo}, the temperature T_{oo}, at which a_{oo} would be the equilibrium concentration, and the temperature T' of the minimum value of the $a_o + x$ curve.

It is interesting to note from Tables V to VIII, and the corresponding Figs. 5 to 8, the similarity of the curves, though the two cooling laws considered: cooling at constant rate and cooling at a rate proportional to the fourth power of the temperature, are nearly the two extremes.

Roughly, a tenfold increase of the cooling rate increases the final NO concentration a_{oo} by about ½ per cent (somewhat more at the higher, less at the lower cooling rates).

With decreasing temperature, on these two cooling laws and thus also any intermediary cooling law, the NO concentration $a_o + x$ follows the equilibrium concentration a_o without appreciable deviation, down to a certain critical temperature. Then the calculated NO concentration $a_o + x$ rapidly rises above the equilibrium concentration, reaches a minimum and then increases again, all within a narrow range of temperature. As stated before, the minimum and the rise at temperatures below that of the minimum are only apparent, due to the approximate equation of $a_o + x$ ceasing to apply, and the actual curve of NO concentration $a_o + x$ reaches a constant value, very little lower than the minimum value of the plotted curve, so that the latter is a fair approximation of the final concentrations.

It is interesting to note that the entire range, from the temperature where the NO concentration still practically follows the equilibrium curve, down to the temperature where the NO concentration has practically become constant, is within a temperature interval of about 100 degrees.

The final NO concentration a_{oo} corresponds to equilibrium concentration a_o, which is very close to the final concentration a_{oo}.

Thus, substituting in equation (58) the cooling function

$$\frac{dT}{dt} = f(T)$$

and substituting $x = 0.001$, gives, for air:

$$f(T) = \frac{T^2 10^{-6}}{21.6}(2ac_2 - 0.493c_1)\left(\frac{2}{a} - \frac{1}{1.554 - a} - \frac{1}{0.42 - a}\right) \qquad (64)$$

This gives the final concentration $a_{oo} = a$, which is derived by the cooling law $f(T)$, provided, however, that the arc temperature is higher than the temperature T corresponding to a.

(Part III will be published in our next issue.)

Government Kelp Plant to Continue Operations

The Government's kelp plant at Summerland, Cal., can be maintained from the returns from its potash output alone. In addition, nearly as much return is made from the four principal byproducts, which are iodine, salt, ammonia and bleaching carbon. The bleaching carbon is being prepared and sold at the Summerland plant at 15c. a lb. In recovering the ammonia enough combustible gas is released to take care of the fuel requirements of the plant.

Testing Natural Gas for Carbon Black

By Roy O. Neal*

BEFORE work is begun on a plant for the production of carbon black from natural gas, the gas should be tested. The actual amounts of carbon black obtained by the same process when using different gas may vary decidedly, as is shown in Table I. The quantity recovered closely follows the percentage of ethane[1], heating value and amount of elementary carbon calculated from the hydrocarbons determined by analysis. The gas from Louisiana has the lowest percentage of nitrogen and the highest percentage of hydrocarbons, namely, 97.56, yet when burned at a factory it gives the smallest yield of carbon black. This is due to the large proportion of methane, which contains 33.5 lb. of carbon per thousand cu.ft., whereas ethane contains 67 lb. of carbon. The two gases from West Virginia have very similar compositions and give approximately the same yield of carbon black. The gas supplied to the plant in Wyoming has the largest calorific value, carbon content and considerably more ethane than any of the other gases and produces the greatest yield. With the richer gases not only the actual quantity of carbon obtained is larger, but also the per cent recovery increases. An examination of the chemical analysis of a gas is probably as trustworthy an indication of the available carbon black as that obtained with a small portable apparatus where gas is burned and the deposited carbon black is collected and weighed.

TABLE I. CARBON CONTENT AND QUANTITY OF CARBON BLACK RECOVERED BY CHANNEL PROCESS

	Louisiana (a) Per Cent	West Virginia (b) Per Cent	West Virginia (c) Per Cent	Wyoming (d) Per Cent
Methane [1]	94.12	70.75	65.23	45.45
Ethane	3.44	24.14	30.07	43.10
Carbon Dioxide	0.50	0.28	1.56	0.96
Nitrogen	1.94	4.83	3.14	9.49
Heating value [2]	962	1,086	1,134	1,176
Lb. carbon per 1,000 cu.ft. of gas [3]	33.8	39.9	42.3	44.3
Reported obtained as carbon black, lb. per 1,000 cu. ft.	0.80	1.00	1.10	1.40
Per cent recovery	2.4	2.5	2.6	3.1

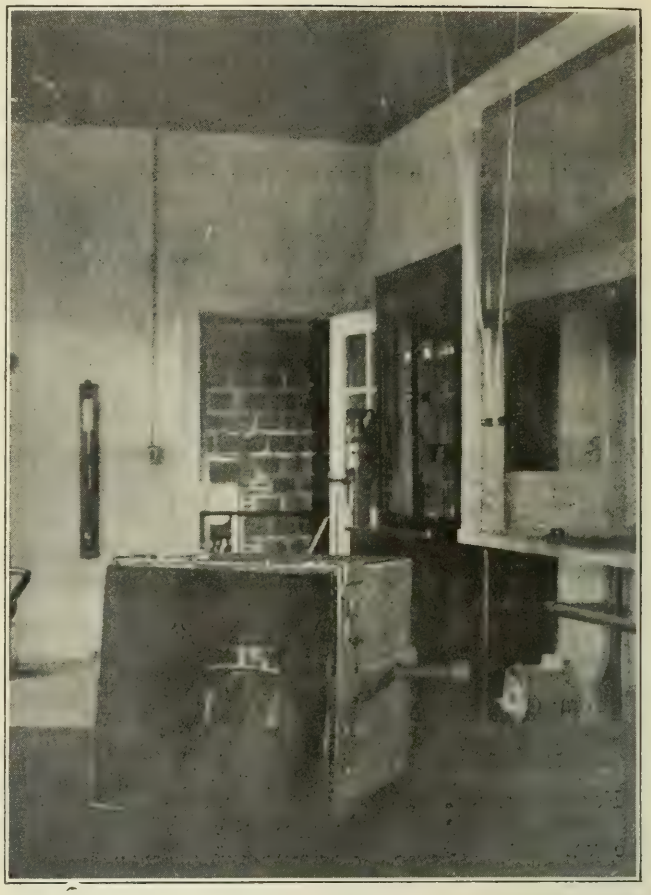

FIG. 2. APPARATUS DETACHED FOR TRANSPORTATION

The writer has designed an apparatus for determining the quantity of carbon black which one might expect to obtain from an unknown gas. Details of the apparatus are shown in Fig. 1. The apparatus is made of 16-gage sheet iron held together with $\frac{1}{8}$-in. rivets. The carbon black is deposited upon a plate 8 x $10\frac{3}{4}$ x $\frac{1}{4}$ in. and is removed by a scraper 1 x 8 x $\frac{1}{16}$ in. that is operated by hand. The draft is controlled by eight 1-in. ventilating holes provided with covers, which are pivoted above the holes, and by a revolving damper located at the top of the hood. The pipe carrying the lava tips can be lowered below the depositing plate and held at any distance by attaching a plug in stopper holes below the supports. The hopper carries a sliding door for removing the carbon black. Lava tips capable of burning about 4 cu.ft. of gas per hr. are used. The hood, hopper and legs are detachable and fit into the central portion of the device to facilitate transporting in the field. The apparatus

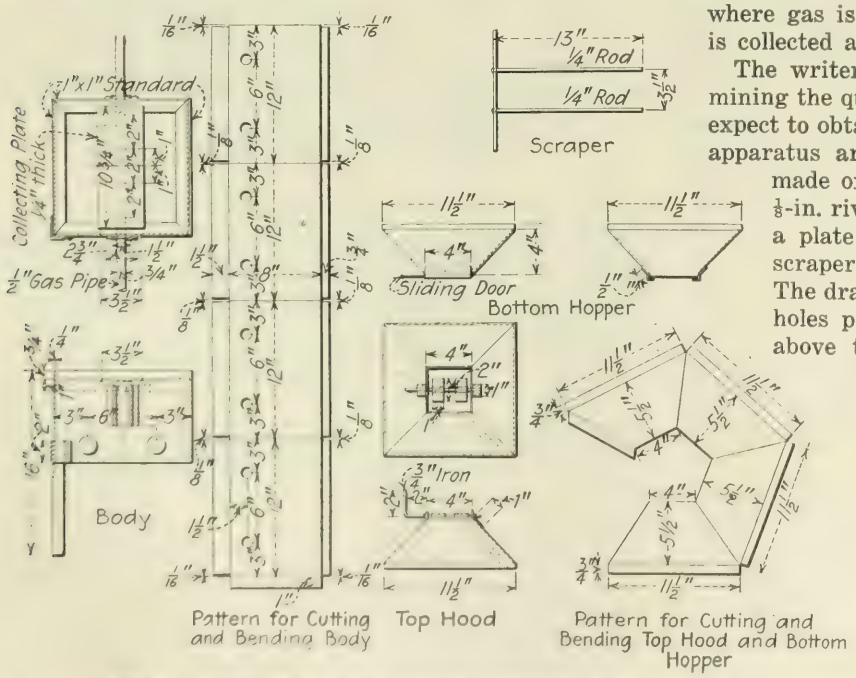

FIG. 1. DETAILS OF PORTABLE TESTING APPARATUS

*Formerly chemical engineer, Petroleum Division, Bureau of Mines.

[1]For the chemical analysis of natural gas the reader is referred to "The Sampling and Examination of Mine Gases and Natural Gas," George A. Burrell and F. M. Seibert; Bulletin 42, Bureau of Mines, 1913. "Gas Analysis," L. M. Dennis, The MacMillan Co., New York, 1913.

ready for transporting in the field is shown in Fig. 2. The apparatus can be used in the field by connecting directly to the supply of gas and using suitable wind breaks if assembled in the field, or can be used in the laboratory by obtaining a sample of gas under pressure in a steel cylinder.

The source of supply of gas is connected with a meter registering at least as small a quantity as one-tenth of a cu.ft. and on this line should be a quarter-inch needle valve in order to limit the flow of gas through the apparatus. Between the meter and the apparatus, where the gas is burned, is attached a "U" tube for determining the pressure of the gas. The top of the lava tips should be about 2½ in. below the depositing plate and a gas pressure of from ½ to 1 in. of water should be maintained. These factors will of necessity be changed when examining different gases and in the preliminary tests changes should be made until the

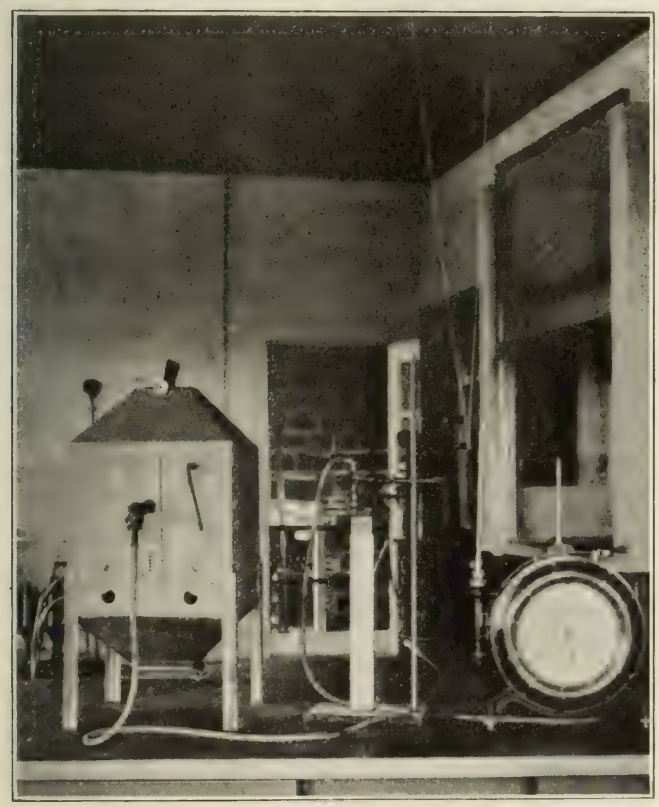

FIG. 3. APPARATUS FOR DETERMINING THE QUANTITY OF CARBON BLACK IN GASES

largest recovery is obtained. A test should last at least an hour, during which time 15 or 20 cu.ft. of gas should be burned. It is possible to make a test without using the meter in the field by previously calibrating the apparatus against a meter in which different pressures on the manometer tube are observed and the time recorded. This will give fairly accurate data on volumes, provided, of course, that the lava tips are not broken, plugged, or partly restricted by foreign matter after the apparatus has been standardized. During the test the carbon black should be removed from the collecting plate by the scraper every 10 min., and at the end of test the carbon which is deposited on the sides of apparatus and plate is removed by use of a small brush. This accumulated carbon black is then weighed. From the data on the volume of gas burned, quantity of carbon black collected and pressure on the gas, the quantity of carbon black which one might expect to obtain in plant operation from a given gas can be calculated. The apparatus assembled is shown in Fig. 3.

In both methods only comparative results are obtained. The portable apparatus will give results approximately paralleling those procured in commercial plants using the channel system, but if some other process is used, it is necessary to standardize the apparatus against a plant where conditions will be similar to those where gas in question is examined.

White Oil Corp.,
Tulsa, Okla.

Relation Between Viscosity and Penetrance of Creosote Into Wood

By Ernest Bateman

IT HAS been generally presumed in the wood preservation industry that the viscosity of a creosote oil is an important factor of the amount of penetration which can be obtained in creosoted woods. The nature of the influence of viscosity, however, has not been worked out. In fact, Bond makes a statement (A. W. P. A., 1913), "that there was no apparent relation between the viscosity of mixtures of creosote with three carbon-free tars and three normal tars and the corresponding absorptions and penetrations into the longleaf pine." Later Teesdale and MacLean in a more comprehensive work (U. S. Department of Agriculture Bulletin 607) state that "the relative viscosities of mixtures of coal-tar creosote and coal tar from different sources are not necessarily a true index of their ability to penetrate wood. In these tests the viscosities of mixtures containing different tars did not appear to have any definite relation to the ease or difficulty of penetration." These statements were based on viscosities as measured by the Engler viscosimeter, which gives a purely empirical measure of the viscosity. Since the publication of Bond's work, Weidner of the United States Bureau of Standards has published (A. S. T. M., 1915) tables for converting Engler numbers to absolute viscosities. The data collected by Bond and by Teesdale and MacLean and also some additional unpublished data have been recalculated to absolute viscosities, with the result that very definite relationships are found to exist between the viscosity and the penetration of creosote in the longleaf pine and noble fir, and it seems likely that the same or nearly the same sort of relation would hold for other species.

Calculated Results

In general the equation $xy = k$, where x is longitudinal penetration, y the absolute viscosity at the temperature of treatment, and k a constant for the wood, appears to answer all the data available on the longitudinal penetration of longleaf pine and noble fir when the treatments were made with 75-lb. pressure for 2 hr. The results of a large number of penetration experiments with different oils in both longleaf pine sapwood and noble fir are given in Fig. 1. The maximum equation of the curve is $xy = 0.6$; the equation of the minimum values is $xy = 0.09$; while the equation of the average values is $xy = 0.3$. The effect of the addition of carbon-free tar and tar containing various amounts of free carbon to the same coal-tar creosote is shown in Fig. 2. The effect is merely that which might be expected from increasing the absolute viscosity of the oil; similarly it can be shown that the effect of raising the temperature of the oil at the time of treatment is

that which would be expected from the change of viscosity which results, provided the other variables are constant. The data available on radial and tangential penetration are not so complete as those for longitudinal penetration; nevertheless such as are available seem to

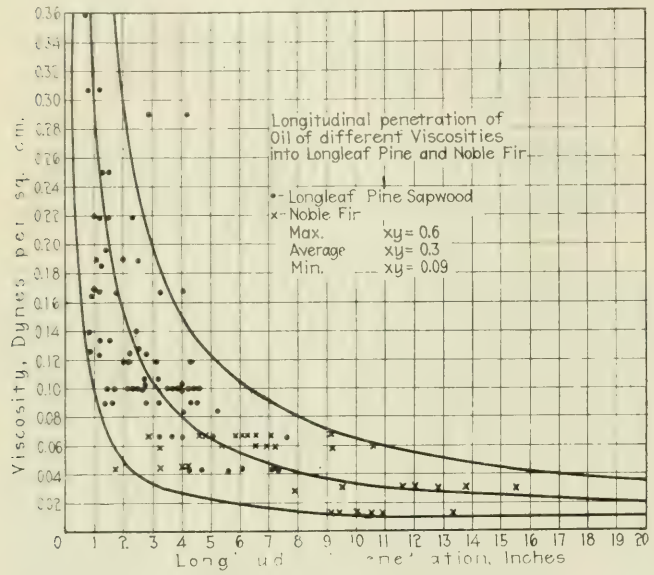

FIG. 1

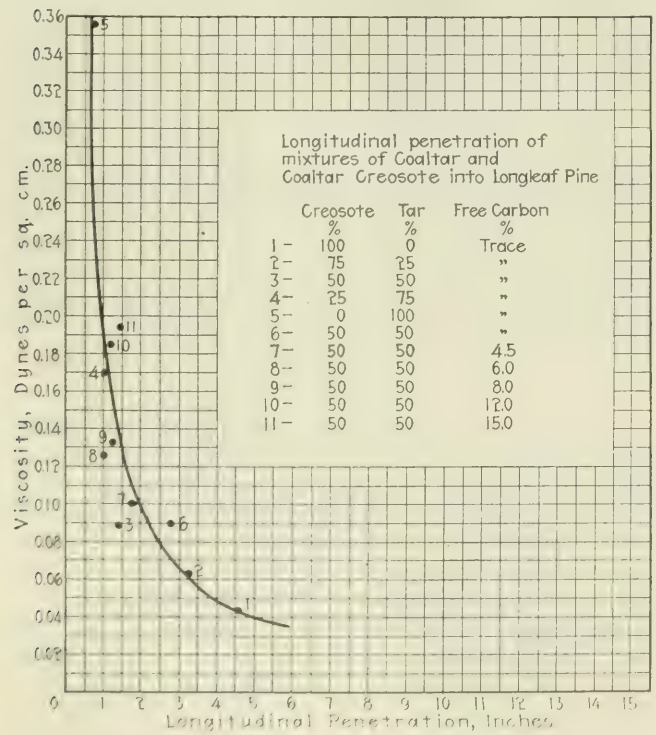
indicate that for noble fir and probably for longleaf pine sapwood the equations are $yx^2 = k$ and $y\sqrt{x^3} = k$ for radial and tangential penetration respectively when the treatments are made at 75-lb. pressure for 2 hr.

There are four variables which will most certainly



Longitudinal penetration of

Longitudinal Penetration, Inches

FIG. 2

affect the penetration of oils in the wood. These are viscosity of the oil, the time during which the treatment is carried on, the pressure at which the oil is applied, and variations in the wood itself. This paper shows the relationship between the viscosity of the oil and the depth of penetration only when all three of the other variables are kept at the values used in the experiment: namely, 2-hr. treatment at a pressure of 75 lb. per sq.in. upon Southern yellow pine sapwood or noble fir. The effect of the other variables and their relationship to penetration is not known except in a general way. We know that in general an increase in the time of treatment increases the penetration of oil, but a penetration is finally obtained beyond which increased time has little or no effect, and the same is true of the relationship between pressure and penetrance; that is, we might expect the curve showing the relationship between penetrance and both time and pressure to take the form of a parabola. The effect of changing all three variables (viscosity, pressure, and time of treatment) at the same time is probably the product of these three equations. It is expected that further work will be done along these lines to prove out the relationship which is here shown.

Conclusions

The following conclusions can be drawn from the work:

1. That a very definite relation exists between the viscosity of the oil and the depth of penetration, and that this relation is amenable to mathematical treatment.

2. That a change in temperature of the oil has no other effect than that of changing the viscosity.

3. That the presence of free carbon in tar-creosote solutions has apparently no other effect than would be expected from the increased viscosity.

4. The following equations hold for longleaf pine and noble fir when the time of treatment is 2 hr. and the pressure 75 lb. per sq.in.

Longitudinal penetration $yx = k$
Tangential penetration $y\sqrt{x^3} = k_2$
Radial penetration $yx^2 = k_3$

where x is the penetration, y the absolute viscosity, k, k_2 and k_3 constants.

5. When the pressure and time of treatment are changed, the power of x and the value of k are changed. Sufficient data are not available to work out the effect of changes in time and pressure.

6. That the measurement of the viscosity of oils intended for treatment is perhaps the most important measurement as far as penetrance is concerned.

Inferiority of Shellac as a Glue

The highest strength value obtained in a recent series of tests where varnished surfaces were glued with casein glue was 1712 lb. per sq.in. and the lowest 1000 lb. Where shellac was used as a binder the maximum shear strength obtained was 1425 lb. per sq.in., the minimum 450, and the average 758 lb. These values indicate that shellac used as a glue is not comparable with casein or animal glues.

Melted shellac or shellac varnish should never be used for binding wood. It has been found during tests of varnished pieces that before a number could be brought to the testing machine they had fallen apart, and where they reached the machine for shearing tests the joint always broke at the joint and not in the wood. This makes it very necessary to clean wood parts which are to be glued, from all varnish or shellac before applying the animal glues.

Milling Plant of the Alaska-Gastineau Mining Co.*

Description of a Gold-Milling Plant Built in the Arctic Regions to Handle Very Low-Grade Ore—A Practicable Process Depended Upon the Low Cost of Roll-Crushing and Low Values in Slimes—Automatic Skip Hoisting in Place of Bucket Elevators Is Another Unique Feature

BY E. V. DAVELER†

THE milling plant of the Alaska-Gastineau Mining Co. is located at the town of Thane, Alaska, on Gastineau Channel, four miles south of Juneau and directly across the channel from the Ready Bullion mine of the Treadwell mines on Douglas Island. Previous to the organization of the Alaska-Gastineau Mining Co., in 1912, the milling was done at the stamp mill of the Alaska Perseverance Co., located at the mine in Silver Bow Basin. But the contemplated increase in production made it necessary to locate the mill on Gastineau Channel, as not enough water was available at the mine during the winter months, nor was there room for taking care of the large tonnage of tailings that would ultimately be discarded from the mill.

CHARACTER OF ORE

The gold and silver values occur in quartz lenses associated with pyrrhotite, galena, arsenical pyrites, and zinc blende. These lenses occur in large bodies of slate, schist and metagabbro, which also carry some valuable metallic contents. With the essential low cost of mining, it was necessary to mine large bodies of low-grade material containing the high-grade streaks. Of the minerals, pyrrhotite, the magnetic sulphide of iron, is predominant, and galena is the next sulphide present in quantity. The gold occurs free and coarse and associated with the iron sulphide in its finer state. The silver occurs with the lead or is alloyed with the gold. A chemical analysis of the ore shows

Silver, oz.	0.10	Magnesia, per cent	0.4
Silica, per cent	59.7	Sulphur, per cent	1.2
Iron, per cent	5.2	Lead, per cent	0.1
Alumina, per cent	21.4	Zinc, per cent	0.2
Lime, per cent	5.0		

EXPERIMENTAL WORK

Investigations at the old Perseverance stamp mill had developed the following points:

Roughing concentration following stamping gives a fair recovery. Practically all gold values are liberated at 50-mesh. Amalgamation of the ore ground through 30-mesh yields 63 per cent of the gold as bullion. An iron concentrate could be made carrying gold and silver values. Slimes were very low in value.

While the experimental plant was being built, laboratory work developed the fact that slimes were consistently low in value, which was of great importance in the later developments of the milling operations.

In Fig. 1 is shown a flow sheet of the experimental mill. This plant had a daily capacity of 75 tons, so all tests were run on this basis in order that results might be comparable with actual milling practice. The roll capacity, of course, was greater, but the concentration department was run at normal tonnage. Machines were so placed that almost any variation desired in the flow could be made. All launders had ample grade and there was very little chance for concentration of values at any place in the mill. Headings and tailings were sampled automatically every 2 min. and hand samples were taken on the products of all machines coincident with the tonnage tests. These were then calculated back against the automatic samples for check.

As proper sampling of the ore was known to be very difficult, due to the coarse particles of gold free in the ore, the greatest precautions were taken. From laboratory tests before starting the experimental mill, it was known that grinding a large sample to 10-mesh was necessary to check results.

The heading sample was taken automatically after roll grinding with maximum size particles of 10-mesh, and on a mill run of 20 tons the heads sample amounted to 400 lb. This sample was rolled very carefully and then riffled through a Jones type sampler with a 1-in. opening. A cut of 50 lb. was obtained and the reject of 350 lb. was saved for other work. The 50-lb. sample was re-rolled and riffled to 12.5 lb., which was ground to 100-mesh and after rolling was cut to about 4 lb., for an assay sample. The 37-lb. cut was saved for screen analysis work. The 350-lb. reject from the first cut was sacked and sent to the Arthur plant of the Utah Copper Co., where check runs were made in the laboratory unit. On the average the variation of all

*A paper presented at the meeting of the American Institute of Mining and Metallurgical Engineers, Feb. 17, 1920.

†Mill superintendent, Butte & Superior Mining Co., Butte, Mont., formerly in charge of experimental work and milling operations, Alaska-Gastineau Mining Co.

runs in the heading assay between the Utah and Alaska results was under 5 cents on the gold assay. In assaying the nail method was used and four three assay-ton charges made on each sample, combining the resultant button for parting and weighing. In the hand-sampling work, six men were used, two sampling each day, and all six men were alternating in the work to eliminate the personal equation as much as possible.

The experimental crushing plant was started with waste to observe the effect of roll-crushing. The ore was low in moisture, running consistently under 2.5 per cent; the ore screened very readily and under ¼-in. size the slate lost its long splintery character and became cubical. The worst problem that developed in the crushing tests was the dust, which was eradicated by sprays; they were also used in the large milling plant. In the concentrating tests, the simplest methods were used first, then these were elaborated as was found necessary.

The first tests were with grinding with the rolls to varying mesh, from 6 to 16; this was followed by primary roughing on Garfield tables and cleaning the rough concentrate on Wilfley tables. Both tables were making final tailing. This method gave a recovery of 75 per cent, a tailing of $0.44, and a concentrate of $13 gold, showing a very satisfactory initial recovery, and work was followed upon tailings from this operation. Screen analysis showed that practically all the gold was liberated from the gangue with 50-mesh grinding. The tailings from the tables were then classified in the

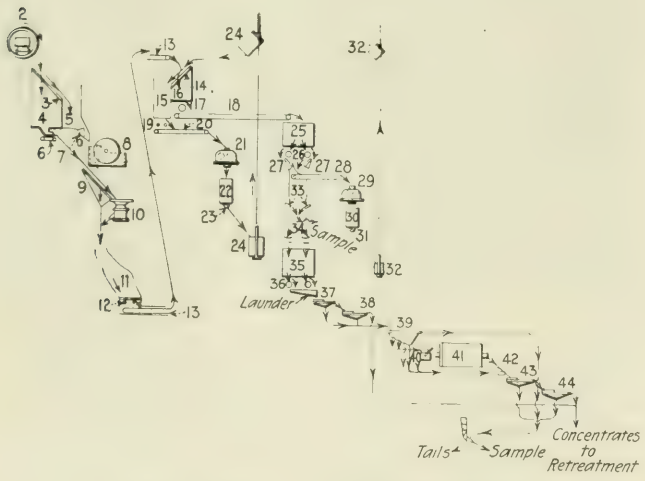

FIG. 2. FLOW SHEET FOR COARSE CRUSHING PLANT, ROLL PLANT AND ONE 2,500-TON SECTION OF CONCENTRATING PLANT

Janney classifier, the material on 50-mesh being reground in the Hardinge mill, and the fine sands sent direct to the secondary roughing tables.

The product from the Hardinge mill was treated separately on both the roughing and the finishing machines, but with the development of the practice it was found that it could be combined with the fine sands from the classifier and treated on the roughing table, the rough concentrate being cleaned on finishing tables. Tailing made on the roughing table on the final test was $0.176; and on the finishing machine $0.32; as the tonnage of the finishing tailings was small, both roughing- and finishing-machine tailings were sent to waste.

The slime overflow from the Janney classifier, comprising about 17 to 20 per cent of the original tonnage, was very low in values, an average assay on all tests being $0.178 gold. Tests were run on this to see if an economical recovery could be made, but nothing satisfactory was worked out. It was then turned to the tail race as waste. This, of course, was one of the most satisfactory developments of the test work.

The above data show that a very economical treatment had been worked out giving high recovery at a low cost. Several check runs made with the flow sheet as adopted showed a tailing of $0.176 gold and an extraction of 89.30 per cent of the gold values. The tonnage of concentrates produced in the final check runs showed that 89.30 per cent of the gold values was concentrated into a product in the ratio of 60 to 1.

Retreatment of Concentrates

Following this, work was started on the retreatment of the concentrates. An average analysis of the concentrates was as follows:

Gold	$80.00	Magnesia, per cent	0.8
Silver, oz	6.30	Copper, per cent	0.1
Lead, per cent	5.2	Zinc, per cent	2.7
Iron, per cent	37.3	Arsenic, per cent	0.2
Silica, per cent	12.9	Tin, per cent	0.1
Alumina, per cent	10.7	Sulphur, per cent	27.0
Lime, per cent	2.2		

The first step in the treatment was to separate the lead concentrate from the iron concentrate, which was easily done on Wilfley tables, using a finger to regulate the cut. This lead concentrate carried all the free coarse gold, a material very hard to sample. Tests showed that this lead concentrate would be separated in a ratio of 857 to 1 as to the original ore milled. The further separation of the free gold from this was left to work out later and attention was paid to the iron concentrate remaining. This iron concentrate carried from $12 to $25 gold values, some silver, and some lead.

The first work was to grind to suitable mesh and amalgamate and reconcentrate. Grinding to 100-mesh liberated the values sufficiently for amalgamation. The iron concentrate, after plating, could then be reconcentrated and a small quantity of iron-lead concentrate of high enough grade to warrant shipping could be made. The final tests showed a tailing of $1.93 gold and $0.26 silver, which with the lead concentrate would mean a shipping concentrate in the ratio of 400 to 1 of the ore milled. At the laboratory in Utah, a tailing of $0.93 gold was made with fresh concentrates; as the concentrates used at Alaska had oxidized somewhat, it was felt that the same results could be obtained in mill practice.

During the winter of 1913, laboratory tests were run at Alaska on cyaniding the iron concentrates to determine whether higher recovery could not be made. The presence of pyrrhotite made this rather difficult, but the method was finally worked out on an economic basis, giving an average recovery of 98.50 per cent of the gold values, with a 4-lb. cyanide consumption. However, the higher cost of the process was a disadvantage, so it was decided to use concentration and amalgamation on the iron concentrates.

Mill Construction

During the experimental work, which lasted until March, 1914, active construction work had been started in the large mill. By February, 1915, with the exception of the retreatment plant, enough of the mill was completed to insure starting operations. Three operating shifts were organized and on duty at the plant

for ten days before the plant started, running machinery available, so that when ore was started through there was practically no delay and the usual troubles of starting a new plant were missing. Actual mill operations were started on March 1, 1915.

Flow Sheet of the Mill

The ore from the different levels is dumped into one of the two ore-ways by 4-ton cars of the Granby type. These two ore-ways are equipped with four underswung arc gates for loading into the 10-ton cars that carry the ore to the mill. At the coarse crusher bins, the cars are spotted in groups of four and dumped by a revolving tipple (2, Fig. 2).

The ore dumped from the cars rolls down a 45 degree slope to a line of 8-in. steel I-beams spaced 10 in. apart and equipped with manganese shoes to take the wear. After over 6,000,000 tons had been dumped on these grizzlies (3), a number of the I-beams had to be replaced, because of bending, but the manganese shoes are still in service. To facilitate the sliding of the wet ore, boiler plate was used; later this was replaced by worn-out roll shells 1 in. thick, which were straightened under the steam hammer at a red heat. This makes a very cheap liner and has a very long life. The oversize from the grizzlies falls into steel bins (5) ahead of the jaw crusher, while the undersize falls into another bin (4).

The undersize from the grizzlies is fed by four 42-in. (106-cm.) wide apron feeders (6) to a stationary crimped-wire screen (9) 3 ft. (0.9 m.) wide and 14 ft. (4 m.) long set at an angle of 45 degrees with 2½ in. (6.35 cm.) openings. The undersize from this screen drops through raises (11) cut in the rock to an underground storage bin, which has a capacity of 8,000 tons. This bin was cut out of the rock during the construction period, the broken rock being crushed in a temporary plant for use as rock and sand in all the concrete used in the mill. It has thus served two useful purposes. At the bottom of the bin there is a reinforced-concrete arch over the tunnel leading to the fine-crushing department.

The oversize from the grizzlies is fed by air-operated arc gates (7) to two 36 x 42-in. (91 x 106-cm.) Buchanan jaw crushers (8) grinding to 5 in. (12.7 cm.) and discharging on 2½-in. (6.35-cm.) stationary double-crimped screens (9); the undersize of these screens drops into the underground storage bin (11). The oversize from all of the 2½-in. screens drops into four No. 8 K Gates gyratory crushers (10), which reduce the feed to pass through a 2½-in. opening. The crushers are of the gun-lock type, the mantles and concaves being of manganese steel. The lower concaves last about eight months on a 16-hr. daily operating basis. Changing the concaves and rezinking an entire set in one crusher takes 8 hr. under normal conditions.

All the crushers are belt driven from a central line shaft, which is divided into two sections so that each side of the plant is independent. The line shaft is of 5 15/16-in. cold-rolled shafting, each unit being driven by a 200-hp. General Electric motor. Mechanically controlled clutch pulleys transmit the power to the crushers through a belt drive. Electric switches are provided so that the operator can cut off power from either the gyratory or the jaw-crusher floor. This plant has a capacity of 3,500 tons in 8 hr. crushing to pass through a 2½-in. ring. The operating crew consists of a crusher man, feeder man, and oiler, per shift; one man and a helper on the day shift do all the routine repair work. Changing of concaves or mantles is done by the rigger crew when needed.

The product from the coarse crushing plant is fed from the bottom of the underground storage pocket by eight rotary feeders (12) to a tunnel conveyer belt (13), which carries it to the fine-crushing section. The rotary feeders are pulleys, 36 in. (91 cm.) in diameter with a 36-in. face, which slowly revolve and pull the ore from chutes attached to the bin bottom. The rotary feeder has a capacity of about 3,000 tons daily with the standard gate opening; different feeders are operated during each 24-hr. period to maintain an even character of ore, as there is some segregation in size in the ore pocket. These feeders are very economical to install and to maintain. After about 4 yr. service some are still in place and the cost of repairs to them has been practically negligible, and wherever possible, they are used throughout the plant. The conveyor (13) discharges ore on four all-steel impact screens (14) of the Colorado type, a modification of the standard impact screen commonly used on finer ore, but strengthened for heavy work. Four screens handle the mill feed of 10,000 tons daily, screening to a 1-in. opening. Double crimped wire screens are used and are made in the shops at the plant.

The oversize from these screens drops into a 2,500-ton bin (15) which acts as storage for the feed to the 72 x 20-in. (182 x 50-cm.) rolls (21). The undersize from the screens drops onto a 42-in. eight-ply conveyor belt (18) and is distributed by a tripper over bins (25) feeding fine impact screens (27). The oversize is fed by a rotary feeder (19) to a 36-in. rubber-covered conveyor belt (20) discharging to 72 x 20-in. rolls (21). The belt and feeders are driven from the roll shaft, insuring stopping of the feed in case rolls are stopped suddenly for any reason. These rolls crush to through 1-in. and the two sets are capable of handling oversize from a 12,000-ton mill feed daily. The product falls into the skip storage bin (22) of small capacity and is elevated by automatic skips (24) to the level of the 42-in. tunnel conveyor discharging over six impact screens. The oversize from these screens then returns to a bin ahead of the 72 x 20-in. rolls.

Elevating by Skip

The ore is hoisted by a 5-ton skip operated automatically by a 75 to 135-hp. Westinghouse hoist motor. The loading mechanism consists of an air cylinder connected to a rod, which opens the gate (23). The air is run into the cylinder through a three-way valve operated by a shaft which is rotated by the descending skip. High-pressure water is available and can be used in place of air. The time of loading is determined by an oil dashpot, which at the same time throws the master switch operating the motor. The time of loading a 5-ton skip is 11 sec., and the complete cycle of operation with two skips operated from the same motor is 1 min. 50 sec. Flat plow-steel cable ⅜ in. x 5 in. (0.95 x 12.7 cm.) is used for hoisting two skips running from the same drum, one loading while the other is dumping. The hoisting distance is 100 ft. (30 m.). This is a new feature in milling practice and replaces dry elevators very effectively. The operating and maintenance cost is quite low, the cost of maintenance being $0.009 per ton milled.

Ore from bin (25) is screened by sixty impact screens (27) of the Colorado type, making 600 vibrations per min. and equipped with 8-mesh 0.032-in. (8.3-mm.) wire-screen cloth and 9-mesh 0.028-in. (7.1-mm.) wire-screen cloth. The screens are equipped with manganese cams and tappets. The undersize from these screens falls to a 36-in. traveling conveyor (34) distributing over the fine bins (35) ahead of the concentrating department. At this point a sample of the mill heads is taken.

The oversize from the screens is conveyed by ten 24-in. (60.9-cm.) belt conveyors (23) to ten 54 x 20-in. (137 x 50-cm.) Garfield rolls (29) set to grind to 10-mesh. The feed to the rolls is sprayed to lay the dust. After grinding, the ore is hoisted by automatic 5-ton skips (32) to the 54-in. roll feed bin and screened as before. Each two sets of rolls are driven by a 300-hp. motor direct connected. The 300-hp. motor is interchangeable with the 300-hp. motor on the 72-in. rolls and the skip-hoist motors are identical with hoists (24). Conveyor and screens are driven from the 54-in. roll shafts.

A 30-ton capacity electric traveling crane operates over the floor of the fine-crushing department and over a large repair room at the end of the floor. The crane facilitates repairs, as any part of a machine can be assembled in the repair shed and then carried to its place. By having a supply of spare parts time lost can be kept at a minimum.

The ten sets of 54-in. fine-crushing rolls have a capacity of 11,000 tons daily, or 1,100 tons per roll to 10-mesh. The 54-in. roll shells give approximately 80 days' actual service and crush 96,000 tons of ore, or 17.6 tons of ore per lb. of steel in maximum operation.

Concentrator

The concentrating department is divided into four independent sections, each of which is equipped with twenty rotary feeders (36), ten primary Garfield tables (37), ten primary Wilfley tables (38), and ten four-compartment Janney classifiers (39), five tube mills (41), ten secondary Garfield tables (43), and ten secondary Wilfley tables (44). Each section then is composed of five parts, each of which can be shut down independently of the others.

The crushed product from the rolls is fed from the fine bins by rotary feeders (36) discharging into a 14-in. (35.56-cm.) launder to the Garfield tables (37). Water is here added for the first time, enough water being added to give proper consistency of feed to the tables. The launders all have sufficient slope so that water added is governed by table conditions.

Garfield tables making the first roughing concentration are double-decked tables 4 ft. (1.2 m.) wide x 12 ft. (3.6 m.) long, with riffles extending the length of the table. The head motion is of special design, very heavy and strong, as experience had shown that exceptionally heavy duty would be required. They produce a rougher concentrate, which is cleaned on Wilfley tables (38) and a tailing, which is laundered to the Janney classifiers (39).

The principle of roughing concentration, which has here been applied to gold milling for the first time, is based on the fact that the roughing table will handle a large tonnage of material per area of deck, giving a low-grade concentrate with high extraction. The low-grade concentrate can then be cleaned on a finishing table. It can easily be seen that the tonnage handled per table will materially cut down the floor space required for mill operation on a large tonnage, thus reducing construction cost and simplifying the subsequent milling operation. In fact, the success of the milling operations at this plant are due to the low cost of roll grinding and to the low cost and high efficiency of the roughing concentration.

The Wilfley tables clean the rough concentrate of the minerals present, rejecting a tailing that joins with the Garfield table tailings and is laundered to Janney classifiers. No. 5 Wilfley tables are used, but the head motion has been strengthened by increasing the size of the shaft and making the thrust bar and pitman of steel instead of iron. The concentrate from the Wilfley table is laundered to the retreatment plant. This concentrate comprises galena, pyrrhotite, sphalerite, and arsenical pyrites, all of which act as carriers for the gold.

Tailings from the primary Garfield and Wilfley tables run to four-compartment Janney classifiers (39). There are ten classifiers in a section, each classifier taking its feed from one Garfield and one Wilfley table. Each classifier, on the standard feed of 2,500 tons daily, is handling 250 tons daily. The maintenance of these classifiers is very small and one operator can look after forty classifiers and twenty tube mills. The classifier makes five products and has two main functions: one to deslime the material so that this slime, which is very low in value, can be rejected, and the other to separate the material coarser than 48-mesh for regrinding, as to liberate the values grinding to 48-mesh is necessary. In the first two spigots all material coarser than 48-mesh is dropped, the third and fourth spigots carry the sands finer than 50-mesh. The classifier overflow, which is all slimes, runs directly to the tail race. The first and second spigots discharge into a shovel or sand wheel box (40), which dewaters the feed and also discards any fine material that might be left in the feed. This combination of classifier with shovel wheel gives an excellent feed to the tube mills, as 90 to 93 per cent of the feed will remain on 48-mesh screen and about 4 per cent of over 48-mesh material passes through the third compartment of the classifier. The moisture to the tube mill is maintained at about 33 per cent.

Grinding Practice

The tube mill used (41) is a cylindrical mill 7 ft. (2.1 m.) in diameter, 10 ft. (3 m.) long, made by the Power & Mining Machinery Co. It is driven by a 75-hp. motor direct connected with a double reduction; the first reduction is through herringbone gear and pinion running in an oil bath, and the second reduction to the mill is by a heavy spur gear and pinion. Komata-type liner is used, the plates being made out of worn-out steel straightened and formed in the blacksmith shop. Lifting bars and screen are made of manganese. Each mill grinds the over-size from 491 tons daily, the product carrying about 30 per cent on 48-mesh. No return of oversize is made. Danish flint pebbles and adamant silica blocks are used for the grinding medium and, in case increase in capacity of the entire mill is made so that more than 10,000 tons is handled daily, additional tonnage can be ground in the mill by using steel balls and increasing the size of motor used. Consumption of pebbles from the beginning of operations has been 1 lb. per ton milled.

The product from the tube mills and the discharge

from the third and fourth spigots of the classifier run to secondary Garfield tables (43), each mill feeding two tables through distributor (42). These tables make a final tailing, which runs to waste. The rough concentrate from each table feeds one No. 5 Wilfley table (44), which makes a tailing to waste and a concentrate which joins the primary Wilfley concentrate and is laundered to the retreatment plant.

Retreatment Plant

From the concentrating department, the concentrates are laundered to elevator pits and carried to the top floor of the retreatment plant by a 12-in. bucket elevator (45, Fig. 3) in each half of the plant. From the elevator the concentrate is distributed to twelve standard No. 5 Wilfley tables (47), which remove a rough lead concentrate carrying all the free coarse gold. This lead concentrate is then retabled on one No. 5 Wilfley table (48) to separate the free gold from the shipping concentrate. This separates some of the coarse lead with

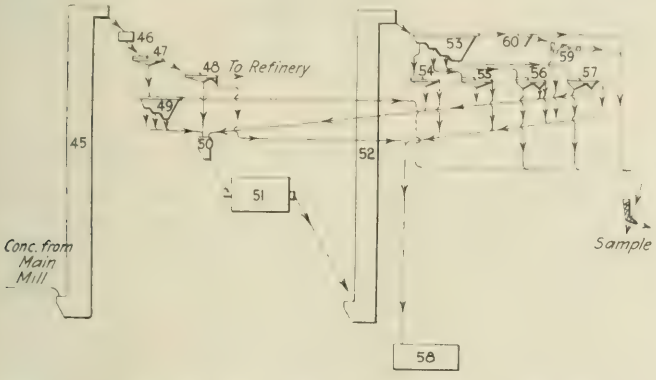

FIG. 3. FLOW SHEET, ONE-HALF RETREATMENT PLANT

practically all of the free gold, the weight of this product being about 1,000 lb. daily. It was treated at first in crucible furnaces, but is now treated in an open-hearth furnace, designed at the plant. Iron shavings are added to take up the sulphur present and the resultant products are a high-grade lead bullion and a matte. This lead bullion can be very accurately sampled and is shipped direct to the smelter.

The reject from the single table in each section handling the lead is a shipping concentrate carrying about $800 gold per ton and about 50 per cent lead. This is stored in bins (58) and shipped as often as boat sailings permit. The tailings from the twelve primary tables are dewatered into a three-spigot Janney classifier (48). The spigot discharge is then ground in a 7 x 10-ft. mill (51) to 100-mesh. After grinding the pulp is elevated (52) to a standard four-compartment Janney classifier (53). The first spigot feeds three Wilfley tables (54) and the second spigot three tables (55). These tables make a concentrate for the shipping bin (58) and a middling which returns to the tube mill (57) for further grinding. The third and fourth spigots each discharge to two tables (56 and 57), which make a concentrate to the shipping bin, a middling which returns for further grinding to the tube mill, and a tailing that goes to waste. The classifier overflow is settled in cone tanks (60) and then fed to six vanners (59), which make a shipping concentrate.

The final shipping concentrate then assays about $400 gold and 40 per cent lead, and 50 oz. of silver per ton; it is in a ratio of 1 to 1,000 of the original ore milled and contains about 44 per cent of the gold recovered, with about 56 per cent in the lead bullion. The tailings from the retreatment plant join the tailings from the concentrating mill, are sampled, and then run to the bay as waste.

Results Obtained

Following is average of series of samples throughout the plant, showing the results of the various concentrations of gold values:

General heads	$1.250	Tube-mill feed	.490
Primary Garfield tailings	.347	Tube-mill discharge	.490
Primary Garfield concentrates	13.150	Secondary Garfield tailings	.170
Primary Wilfley tailings	.844	Secondary Garfield concentrates	5.450
Classifier feed	.523	Secondary Wilfley tailings	.460
First spigot classifier	.600	Secondary Wilfley concentrates	5.360
Second spigot classifier	.320	General concentrating tails	.177
Third spigot classifier	.260	Retreatment tails	1.000
Fourth spigot classifier	.260	General tails	.200
Classifier overflow	.160		

The average value of the concentrate going into the retreatment plant is about $70 gold per ton; and after the initial lead concentrate is made, iron concentrate which is reground and treated is left, assaying $19 per ton. After treating a tailing of $1 is made.

TABLE I. GENERAL HEADS

	Mesh	Per Cent Material	Cumulative per Cent Material	Assay	Per Cent Value	Cumulative per Cent Value
Plus	10	2.5	2.5	$0.83	1.5	1.5
Plus	20	27.7	30.2	1.24	24.6	26.1

Minus	200	49.00	100.00	1.03	58.67	100.00
		100.00		$0.86	100.00	

Characteristic screen analyses of the mill heads, mill tailings and retreatment tailings are as shown in Table I, Tyler standard screen sieves being used.

Results

The work has shown that economic grinding of the ores for final concentration is through 48-mesh; that the slimes carry very low values; and that regrinding and concentration of the iron concentrate will liberate the gold values, permitting the iron to be thrown away. This, of course, reduces the smelting costs and losses to a minimum. Also, the lead concentrate produced carries 40 per cent lead, which is a good smelting product.

Concentrates are sacked and shipped to the Selby Smelting Co. for treatment. At the beginning of operations we were using amalgamation as an additional process in the retreatment of our concentrates but found this unnecessary.

Great pains are taken at the mill to insure accurate sampling of all vital products. For the headings to the concentrating departments, the undersize from each screen is sampled automatically and cutters ½ in. (12.7 mm.) wide are operated by a Scobey timing device throwing the four-way air valve connected to the air cylinder. A cut is taken every 12 min. and samples are collected every 24 hr. On a basis of 6,000 tons of ore milled, the combined sample averages about 3,000 lb., or ½ lb. per ton milled. This is carefully coned and ringed several times and then quartered, opposite quarters being saved together and about a 50-lb. sample cut from each of the two cuts by additional ringing and coning. These then are ground to 700-mesh in the laboratory and riffled to assay pulp size, weighing about 4 lb. each.

The assayer runs four charges of two assay-tons each on each sample, combines the resultant silver-gold buttons, and then parts and weighs them together. The average of the original and the duplicate is then taken as the average for the day.

The stream of tailings from each half of the mill is cut by an automatic sampler every 10 min. operated as for the head sample. These samples, amounting to 150 lb. each, are collected at the end of every shift. They are rolled and riffled, a 10-lb. sample from each shift sample being put through the pulverizer and ground to 100-mesh. From each of these shift tailing samples, the assayer runs four samples, each of three assay-tons, making a total of twelve crucibles for the three tailing samples.

Concentrate production is sampled automatically and at the time of shipment an auger sample is taken from each sack. Special sampling of different products throughout the plant is kept under way at all times.

Costs of Operation

While the plant has not treated its full tonnage, the results of operating in the year 1917, when for a period the tonnage was maintained at 7,023 tons, gives an idea of what costs will be under full operating basis. These costs are as follows:

Coarse crushing	$0.02804	Labor cost	$0.09746
Fine crushing	.09432	Supplies	.05454
Concentrating	.05136	Shop expense	.03787
General mill	.02778	Sundries	.04970
Power and light	.01467		
General overhead	.02340	Total	$0.23957
Total	$0.23957		

Potash Statistics

The following statistics, from German official sources, quoted by the *Fortnightly Information Review* of the American Chamber of Commerce in France, show the foreign and domestic sales of German potash salts, K_2O.

Year	Domestic Sales, Tons	Foreign Sales, Tons	Total, Tons	Value in Marks Calculated on Legal Prices	Value in Dollars at Par	Percentage Used in Agriculture	Percentage Used in Industry
1910....	460,618	346,473	807,091	133,800,000	$31,800,000	88.3	11.7
1911....	527,822	441,941	969,763	160,100,000	38,100,000	90.5	9.5
1912....	581,422	524,514	1,105,936	186,400,000	44,400,000	89.5	10.5
1913....	664,711	556,695	1,221,406	202,500,000	48,200,000	90.4	9.6
1914....	591,590	402,797	994,387	164,500,000	39,200,000	91.2	8.8
1915....	623,807	123,947	747,754	111,700,000	26,600,000	92.0	8.0
1916....	797,548	174,825	972,373	163,900,000	39,000,000	94.1	5.9
1917....	958,625	146,084	1,104,709	230,500,000	54,900,000	95.7	4.3

The statistics in Table I of the consumption of actual potash—K_2O (German)—in agriculture, not including industry, in the most important consuming countries, are also taken from German official sources. The quantity is given in short tons.

Durability of Cement Drain Tile in Alkali Soil

After an interruption of two years, due to the pressure of war work, the field inspection and testing in connection with the drain tile in alkali soils has again been taken up by the Bureau of Standards, Department of Commerce. In Minnesota, pieces of tile which have been in the ground since the last inspection have been removed for test and the concrete was found to be uninjured either by alkali or acids, but a number of both the best and poorest tile was found to be cracked. It is thought that some time during the cold weather water had backed up and stood in the pipe, freezing and bursting it. A complete survey of all the most important reclamation projects in the West is to be made in the near future, and based on this work the committee in charge of the investigation will endeavor to make definite recommendations relative to the manufacture and use of cement tile in alkali soils. The results of the work already accomplished are embodied in the Bureau's Technologic Paper T95, "Durability of Cement Drain Tile in Alkali Soil."

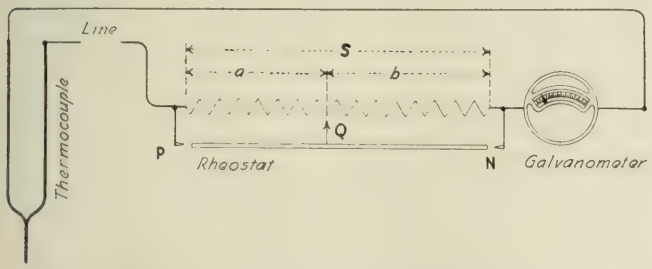
Simple Pyrometer Adjustment

IN THE practice of pyrometry it is often difficult to bring about in the student's or user's mind an adequate appreciation of the several variables and electrical quantities to be considered. It is decidedly easier to teach the operator to read a galvanometer type instrument than to train him to employ a potentiometer or balancing type of meter. Quite often he is more impressed with the simplicity of the direct reading instrument than he is with its errors, with the result that the potentiometer, or adjusting type of instrument, suffers by comparison in his judgment.

As has been shown by many writers, resistance is the most uncontrollable source of error. It is therefore highly desirable, if this source of error is to be eliminated with the user's full appreciation, to teach him to measure it or compensate for it. A circuit described by Dr. E. F. Northrup in the current *Pyrolectric Bi-Monthly Bulletin* may be simply explained as follows:

In the accompanying figure an ordinary rheostat is placed in series in circuit. The resistance of the galvanometer is ordinarily known, being stamped on the instrument, and may be represented by the letter G.



Similarly the total resistance of the rheostat is designated by S, while the unknown resistance of thermocouple and line is called x. The problem is first to discover the value of the resistance of the entire circuit when in operating order.

Proceed as follows: Place the thermocouple in a hot furnace at equilibrium, close switch N and open P; then move the sliding contact Q on the rheostat to the left until the resistance a is zero and the deflection D of the meter is at its maximum. This gives the same meter reading for the temperature in question as though the line were connected directly to the galvanometer in the usual way, without rheostat in circuit and the total resistance, which may be called R_1, is $G + x$.

$$R_1 = G + x \qquad (1)$$

This deflection D is noted, and without changing the switches, move slides Q to the right until sufficient additional resistance a has been thrown in circuit to reduce the deflection by one-half. Galvanometer now reads $\frac{D}{2}$, the total resistance through which the current is passing is $G + x + a$ and may be called R_2, or

$$R_2 = G + x + a \qquad (2)$$

Now, without disturbing the slides Q, reverse the switches, opening N and closing P. The resistance, R_3, of the entire circuit, including galvanometer, line, rheostat and thermocouple, after this adjustment exactly equals S, the total resistance of the rheostat.

This is easily proved as follows:

Since adding resistance a to the circuit cut the deflection of the galvanometer in half, by that evidence it cut the current flowing in half. Now, since the applied electromotive force generated by the thermocouple is constant, it being held at uniform temperature, if the current is cut in two it was because the resistance of the circuit was doubled. Hence $R_2 = 2R_1$

Substituting from equations (1) and (2)

$$G + x + a = 2(G + x)$$

Simplifying $$a = G + x \qquad (3)$$

But the final course of the current is from thermocouple through line and switch P to slides Q and thence through resistance b to the galvanometer. Neglecting as before the resistance of the rheostat bar between P and N, the total resistance of the adjusted circuit equals the sum of the resistance of thermocouple, line, galvanometer, and coil b. In symbols

$$R_3 = x + G + b$$

but from equation (3) $G + x = a$. Hence, substituting

$$R_3 = a + b$$

By definition of a and b, they are the component parts of the rheostat, so that $a + b = S$. Or,

$$R_3 = a + b = S$$

In other words, the resistance of the adjusted circuit is equal to that of the total rheostat, which was what we set out to prove.

As remarked at the outset, variable resistance in thermocouple and line are responsible for the chief uncertainty in direct reading instruments. Here, then, is a simple method, where merely by a rheostat and a double throw switch, it is possible to correct a galvanometer for all errors due to line drop or extraction of current from high resistance shunt. When it is desirable to confirm any stationary needle reading, it can be done very quickly as follows: Reverse switches, run slide to zero, note deflection, draw deflection down one-half by sliding back contact Q, reverse switches, and check dial against former reading. The thermocouple resistance and the galvanometer resistance are measured in terms of the current sensitivity of the galvanometer, a factor that is practically constant, having a very slight change with temperature. It is believed to be a new method whereby the measurement of resistance is accomplished and expressed in terms of the galvanometer "current constant."

The relative error of setting is small in direct proportion as $b + x$ is small in comparison with g. Also the error of setting for $\frac{D}{2}$ is inversely increased with the reduction in the value of D.

Much has been written relative to the errors involved in the use of a galvanometer for measuring thermocouple electromotive forces. In general, it may be said that accuracy with a galvanometer is secured only at the sacrifice of durability, unless manual adjustment is made in the operation of the instrument to overcome the errors of resistance and resistance changes. The pyrovolter and the potentiometer both require manual adjustment for every reading, readings being taken on a "null" method.

It is believed that the circuit described will assist in impressing on operators the various sources of trouble in a thermocouple circuit and their relative importance and will suggest a method for overcoming them.

The following characteristics of this circuit may be of interest. Maximum allowable resistance in thermocouple circuit external to instrument is $M = s - g$. The emf. range of the instrument is given by $E = SI$, where I is the current required to deflect the galvanometer to full scale.

Legal Notes

Manufacturer and Seller of Tool Steel Warrants His Product—"High-Speed" Steel Not a Trade Name

THE uniform sales act has been adopted in most of the states. All sales contracts made therein must be construed according to decisions interpreting its provisions. The Supreme Court of Pennsylvania recently had occasion to pass upon a New York sales contract, the goods having been sold f.o.b. the point of shipment in New York to a manufacturer in Pittsburgh, Pa.

The Reliance Steel & Tool Co. of New York sold to the Metal Product Co., manufacturer in Pittsburgh, certain high-speed steel for the making of tools. When the steel arrived it appeared to be in good condition, but after expenses had been incurred by the manufacturer in its attempt to make the tools, it was found unfit for the purpose, or any other manufacturing purpose, and only valuable as scrap iron. Thereupon the buyer refused to pay. The seller brought suit for goods sold and delivered. (107 A., 713.)

Matters Involved in the Dispute

Upon trial of the cause there was no question raised as to the quantity of steel received, nor as to prices and credits allowed. There were three matters involved in the dispute, as follows: Was the steel of a quality reasonably fit for the making of tools? Was there an express warranty it should be so fit? And was there an implied warranty it should be reasonably fit for the purpose, because of seller's knowledge of the purpose for which it was purchased? Now, the seller admitted he knew the purpose for which the steel was purchased. The trial court gave judgment for the seller, and the buyer appealed to the Supreme Court, which reversed the judgment in the case.

Provisions of the Sales Act

On the appeal the last of the three questions was the important one to be determined. Its proper answer lay in the following provisions of the sales act, which provides:

"Where a buyer, expressly or by implication, makes known to the seller the particular purpose for which the goods are required, and it appears that the buyer relies on the seller's skill or judgment (whether he be the grower or manufacturer or not), there is an implied warranty that the goods shall be reasonably fit for such purpose. . . .

"In the case of a contract to sell or a sale of a specified article under its patent or other trade name, there is no implied warranty as to its fitness for any particular purpose.

"Where there is a breach of warranty by the seller, the buyer may, at his election, (*a*) accept or keep the goods, and set up against the seller the breach of warranty by way of recoupment in diminution or extinction of the price.

Measure of Damages for Breach of Warranty

"The measure of damages for breach of warranty is the loss directly and naturally resulting, in the ordinary course of events, from the breach of warranty.

"In the case of a breach of warranty of quality, such loss, in the absence of special circumstances showing proximate damage of a greater amount, is the difference between the value of the goods at the time of the delivery to the buyer and the value they would have had if they had answered to the warranty."

Supreme Court Holds That "High-Speed Steel" Is Not a Trade Name

The trial court held that "high-speed steel" is a trade name under the section above, and hence there was no implied warranty as to its fitness for any particular purpose. The Supreme Court said this was erroneous. There was evidence as to what constituted high-speed steel, and that each manufacturer thereof had a separate and distinct trade name for the particular high-speed steel manufactured by him. The generic name of an article made by several is not a trade name.

The seller was permitted to produce evidence of an alleged general custom in trade—contradicting the provision of the sales act quoted above—to the effect that, if a buyer discovers defects in high-speed steel, his only right is to return it and receive credit for the contract price. This was error, the court held.

Further, it held to be error to refuse to permit the buyer to show the expense incurred in the endeavor to make tools from the steel, before it discovered the impossibility of so doing. This objection was based on the provision above which says a buyer is entitled to set off only "the loss directly and naturally resulting in the ordinary course of events," which, "in the absence of special circumstances showing proximate damage of a greater amount, is the difference" between the value of the steel as it was and as it would have been had it "answered to the warranty." The court said it is difficult to understand what loss could more directly and naturally result, in the ordinary course of events, than the initial expenses incurred in using the steel, when the defects in it were not discoverable otherwise. That such expenses are allowable, if not too remote, has often been decided, both before and since the passage of the sales act.

It was contended by the seller that there was no implied warranty in the sale that the goods were fit for the purposes sold. Before the uniform sales act was passed the courts had held repeatedly that there was such an implied warranty so far as relates to the grower or manufacturer of the goods sold, and the only change made in the rule by this act was to extend it to include every seller, "whether he be the grower or manufacturer or not."

Law Implies Seller's Warranty of the Product

In an earlier case (28 L. Ed., 86) the Supreme Court of the United States said on this point:

"When, therefore, the buyer has no opportunity to inspect the article, or when, from the situation, inspection is impracticable or useless, it is unreasonable to suppose that he bought on his own judgment, or that he did not rely on the judgment of the seller as to latent defects of which the latter, if he used due care, must have been informed during the process of manufacture. If the buyer relied, and under the circumstances had reason to rely, on the judgment of the seller, who was the manufacturer or maker of the article, the law implies a warranty that it is reasonably fit for the use for which it was designed; the seller at the time being informed of the purpose to devote it to that use."

The Demand and Supply of Fixed Inorganic Nitrogen in the United States

A Concise Review of Our Present and Future Needs of Nitrogen and of the Advantage Resulting in the Continuous Operation of the Government Nitrate Plants to Help Supply Industrial and Agricultural Requirements

By ALFRED H. WHITE

THE United States uses fixed nitrogen for three main purposes—food, fertilizer, and chemical manufacture. The first two items are linked together, for the nitrogen fixed in foods is drawn from the soil, and provision must be made for the soil's replenishment. Provision for the increased food supply which this country needed during the war was hampered by lack of nitrogenous fertilizer. The increased cost of farm labor, and the increased value of crops, as well as the constant impoverishment of the soil, all point to the use of fertilizers in areas where they have not previously been used and their more liberal use on fields where they have formerly been used. It is safe to assume that nitrogenous fertilizers will be used in progressively increasing measure during the next decade at least.

One branch of the chemical industry of the country—that of explosives—was enormously stimulated during the war and has dropped down to approximately pre-war levels. The use of commercial explosives may be expected to grow with the development of the various industries in which they are used. Certain industries, notably the dye industry and those connected with the manufacture of artificial leather, photographic films, celluloid and other products of nitrated cotton, are requiring vastly increased amounts of nitric acid. These industries are still infants and may, if properly encouraged, be expected to grow materially faster than the average manufacturing industry of the country.

Organic and Inorganic Nitrogen

There are two fairly well recognized divisions of fixed nitrogenous products—organic and inorganic. The organic products are typified by tankage, dried blood and other products from the slaughter houses, and by the oil cake and hulls from the cotton plant. These products formerly went mainly to fertilizer, but in more recent years have been diverted more and more into food for cattle. Within a few years almost all of the oil cake and a considerable part of the high-grade tankage will be diverted away from fertilizer. The amount of organic nitrogen available for fertilizer is therefore decreasing and certainly no increase in it can be expected. The inorganic nitrogen compounds divide themselves into two broad classes—nitrates and ammonia compounds. These are not strictly interchangeable in either the fertilizer or the chemical world, but fortunately they are exchangeable to a considerable extent, and ammonia compounds are also convertible to nitrates, so that the world can increase its stock of either form in the full confidence that it will be used. The ammonia compounds of this country come almost entirely from the coke ovens and gas works. A relatively small amount comes from cyanamide obtained by fixation of atmospheric nitrogen at one plant at Niagara Falls. The nitrates come exclusively from Chile, on the west coast of South America.

Fixed Nitrogen as a Basis for Calculation

Since the United States can use both ammonia and nitrates, it is simpler, for purposes of study, to make all calculations in terms of fixed *nitrogen*, without reference to its source as ammonia or nitrate. Since the supply of organic nitrogen available for fertilizers is actually decreasing, it is clear that any increase in the amount of fixed nitrogen used by the chemical or fertilizer industries must come from inorganic sources.

The attached chart shows graphically the consumption of inorganic fixed nitrogen by the United States from 1902 to 1918, together with possible future developments. The development from 1902 to 1915 is fairly normal. The next four years reflect the war conditions and are so abnormal that they should not be considered in plotting future demand.

Future Demand for Fixed Inorganic Nitrogen

The graphs for the total consumption of inorganic nitrogen show an increase of nearly 200 per cent in the decade 1902-1912. The fluctuations are too great to permit any exact curve being traced, but the increase is very nearly linear and increases at the rate of 9,100 tons of nitrogen a year. If this line is projected to 1930, it shows a consumption of 300,000 tons of inorganic nitrogen for that year as indicated by line *E* of the chart. This is certainly low, for a flat increase of 9,100 tons means a decreasing rate which will have dropped to only 3 per cent annually at the end of this period. This could hold true only if the agricultural and chemical fields were becoming saturated. The contrary is the case, for the chemical industries of the country are growing rapidly, and the agricultural field, having not yet appreciated the economic advantage of nitrogenous fertilizers, will be only beginning to realize the full advantage of a more liberal use of fertilizer by that date.

It is therefore safe to assume a progressive increase in the total demand for nitrogen. Two graphs for this have been constructed, one portraying a 10 per cent cumulative annual increase, commencing with 1902 (line *G* of the chart), and the other a 7 per cent cumulative annual increase starting with a normal figure of 145,000 tons of inorganic nitrogen in 1913 (line *F* of the chart). The curve of 10 per cent increase lags throughout the pre-war period, and it is not certain that it indicates too rapid increases in the post-war period, although it does lead to rather startling figures. If the United States should continue to use fixed inorganic nitrogen at a cumulative 10 per cent annual increased rate, it would require, in 1930, 676,000 short tons of nitrogen, which,

translated to terms of nitrate, corresponds to 3,900,000 long tons of Chilean nitrate, more than twice as much as this country imported even under the stress of war and 25 per cent more than Chile can produce. If a 7 per cent cumulative increase is adopted as being more probable, it points to a total demand in 1930 of 458,000 tons of inorganic nitrogen, which, if supplied entirely from Chile, would require 2,600,000 tons of nitrate, which is nearly Chile's maximum output.

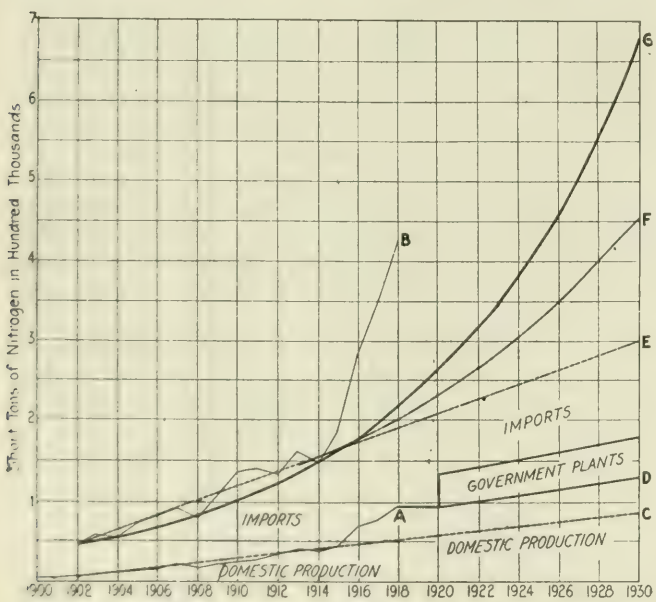
Of course it will not all be imported from Chile. Much of it will be produced at home, as ammonia compounds, and some may be imported as ammonia salts from European nations. The situation in 1913 is shown more fully in Table I.

The figures for nitrogen supply are all taken from the tables in the American Fertilizer Handbook, most of which are derived from official Government reports. The figures for utilization of sodium nitrates are taken from the report of the Federal Trade Commission (Senate Document 551, 64th Congress) on the Fertilizer Industry. The Commission received reports from six informants in close touch with the nitrate situation, whose averaged estimates for 1913 are as follows:

	Per Cent	Tons of Chilean Nitrate Based on 626,000 Tons Imports
Explosives	39.2	245,400
Fertilizers	45.5	284,800
Chemicals, etc.	15.3	95,800

The figures for utilization of ammonia are from an unpublished Government estimate.

The chart shows that the production of fixed inorganic nitrogen in the United States rose steadily in the period 1902 to 1915, but not so fast as the demand of the country, so that in the latter years of the period the importations were twice as great as in 1902. Even the great growth of the coke ovens during the war has failed to bring the American production of inorganic nitrogen up to within 100,000 tons of the normal demand. The curves show that if all the imports were from Chile, there would, on a normal basis, have to be at least 600,000 tons of nitrate imported in 1920.



INORGANIC FIXED NITROGEN TOTAL CONSUMPTION OF UNITED STATES

A and *B*. Total domestic production and imports for 1918.

C. Total estimated domestic production up to 1930 on the assumption of an annual increase of 2,800 tons, beginning 1902 (approximately normal previous to war).

D. Total estimated domestic production up to 1930 on the assumption of an annual increase of 3,700 tons after 1920.

E. Total estimated demand up to 1930 on the assumption of an annual increase of 9,100 tons (approximately normal during the decade 1902-1912).

F. Total estimated demand up to 1930 on the assumption of an annual cumulative 7 per cent increase over normal 1913 consumption.

G. Total estimated demand up to 1930 on the assumption of an annual cumulative 10 per cent increase over 1902 consumption.

TABLE I. STATISTICS FOR FIXED INORGANIC NITROGEN FOR U. S. IN 1913

1913 Supply of Fixed Inorganic Nitrogen[1]	Nitrogen Short Tons
Chilean nitrate, 626,000 long tons	109,000
Imported ammonium salts calculated as sulphate = 65,775 short tons sulphate	13,550
Domestic production of ammonia from coke ovens and gas works calculated as sulphate = 195,000 short tons sulphate	40,200
American Cyanamid Co. 15,000 tons cyanamide	3,000
	165,750

1913 Utilization of Fixed Inorganic Nitrogen		Nitrogen Short Tons
Imported Chilean Nitrate[2]		
Fertilizer	245,400 long tons[2]	
Explosives	284,800 long tons	
Chemicals, glass, etc.	95,800 long tons	
	626,000 long tons[1]	
	701,000 short tons	109,000
Ammonia:		
Sulphate for fertilizer	130,000 tons	26,800
Cyanamide	15,000 tons	3,000
Ammonia for essential industries		30,000
		168,800

[1]The American Fertilizer Handbook.
[2]Report on Fertilizer Industry by Federal Trade Commission, Senate Document 551, 64th Congress.

Future Domestic Production

The future domestic production depends largely on the byproduct coke ovens. Their rapid increase during the war has increased the production of byproduct coke so that in normal times approximately two-thirds of the coke will probably be produced in byproduct ovens.

The future increase in coke ovens will probably correspond somewhat closely to the growth of the pig iron industry, which takes by far the larger part of the coke made. The growth of pig iron production was almost exactly 50 per cent between 1905 and 1915. It will probably not increase so rapidly in the next decade. The assumption is therefore made that the production during the years 1919 and 1920 will be the same as in 1918, and that 1930 will show an increase of 40 per cent over 1920 in pig iron, and byproduct coke-oven coke and its resultant fixed nitrogen. This is shown on the chart as line *D*. It will be seen that it falls far short of meeting the fixed nitrogen demands of the country.

Future Fixation of Atmospheric Nitrogen

The two lines of fixation of atmospheric nitrogen which were largely developed during the war were the cyanamide and the Haber processes. Neither of them affords any definite promise of profitable *commercial* operation in this country in the near future. The cyanamide process requires too much electrical energy and the Haber process needs further study and development before it can be considered a commercial success. Nevertheless this country cannot afford to fall behind in the development of nitrogen fixation. The Chilean nitrate supplies are waning and sooner or later reliance will have to be placed on fixation processes.

Utilization of Government Plants

Fortunately, the United States Government is well fitted to carry on the work of nitrogen fixation. It has

in its Nitrate Plants Nos. 1 and 2 exemplifications of the two main types of processes. The cyanamide plant is of superior design and can be operated as a Government plant to produce fertilizer at a cost which will pay running expenses at the lowest price which fixed nitrogen is likely to reach, due to the fact that it has very cheap electrical energy, which will be produced at its hydro-electric plant at Muscle Shoals. It should return some interest to the Government on the investment. These plants should certainly be operated. When working at full capacity they will fix 50,000 tons of nitrogen a year. As shown by the chart, this is still entirely inadequate to meet the prospective demand. The figures are given more fully in the Tables II, III and IV.

TABLE II. FORECAST OF DEMAND AND SUPPLY OF FIXED INORGANIC NITROGEN IN U. S. FOR 1920

	Nitrogen Short Tons
Demand:	
Based on a normalized figure of 145,000 tons (as shown by the chart) in 1913 with an assumed normal increase of 7 per cent compounded annually. Factor for 7 per cent for 7 years = 1.60.	
Total demand, 145,000 × 1.6	232,000
Sources of Supply:	
Coke ovens, gas ovens and plant of American Cyanamid Co., estimated as same as 1918	92,700
Balance to be made up	139,300
Possible production from U. S. Nitrate Plant No. 2	41,500
Balance to be imported	97,800

Importations to be made up by Chilean nitrate or foreign ammonium sulphate:

	Per Cent of Total Supply to be Imported	Chilean Nitrate Equivalent in Long Tons
If Government nitrate plants are operated	42.1	508,000
If Government nitrate plants are not operated	60.4	710,000

TABLE III. FORECAST OF DEMAND AND SUPPLY OF FIXED INORGANIC NITROGEN IN U. S. FOR 1925

	Nitrogen Short Tons
Demand:	
Demand based on 1913 normalized figures from chart with increase of 7 per cent compounded annually. Factor = 2.25.	
Total demand 1925 = 145,000 × 2.25	326,000
Sources of Supply:	
Domestic coke ovens, gas ovens and private cyanamide plants with assumed increase of 20 per cent over 1920	111,240
Balance to be made up	214,760
Possible production from U. S. N. P. Nos. 1 and 2 41,500 + 8,500	50,000
Balance to be imported	164,000

Importations to be made up by Chilean nitrate or foreign ammonium sulphate:

	Per Cent of Total Supply to be Imported	Chilean Nitrate Equivalent in Long Tons
If Government nitrate plants are operated	50.5	947,000
If Government nitrate plants are not operated	66.0	1,234,000

Effect of Government-Owned Plants

As shown by the chart and the accompanying tables, there need be no fear that the present Government nitrate plants can in any way flood the market. They will serve to decrease the reliance which must be placed on Chilean or foreign sources and they will serve as a focus from which knowledge of the fixation art may be spread abroad through the country. Improvements may be expected from their research laboratories, and inventors of new processes will be assured of sympathetic assistance. The plants certainly will maintain themselves without expense to the Government and will return a dividend to the Government on its investment. If the future price of inorganic nitrogen rises at all proportionately to the price of other commodities, the net earnings should be considerable. The effect of the Government plants in reducing importations on the basis of the 7 per cent cumulative increased demand already discussed is shown in the following table:

TABLE IV. FORECAST OF DEMAND AND SUPPLY OF FIXED INORGANIC NITROGEN IN U. S. FOR 1930

	Tons
Demand:	
Demand based on normalized 1913 figures from chart with increase of 7 per cent compounded annually. Factor = 3.16.	
Total demand 1930 = 145,000 × 3.16	458,200
Sources of Supply:	
Domestic coke ovens, gas ovens and private cyanamide plants with assumed increase of 40 per cent over 1920	130,000
Balance to be made up	328,200
Possible production of U. S. N. P. Nos. 1 and 2	50,000
Balance to be imported	278,200

Importations to be made up by Chilean nitrate or foreign ammonium sulphate:

	Per Cent of Total Supply to be Imported	Chilean Nitrate Equivalent in Long Tons
If Government nitrate plants are operated	60.7	1,600,000
If Government nitrate plants are not operated	71.6	1,900,000

ESTIMATED PERCENTAGE OF INORGANIC NITROGEN REQUIREMENTS WHICH MUST BE IMPORTED

	Government Nitrate Plants in Operation	Government Nitrate Plants Idle
1920	42.1	60.4
1925	50.5	66.0
1930	60.7	71.6

Surely, with the lessons of the war still fresh in mind, this country cannot afford to count on the importation of more than one-half of the inorganic nitrogen, vital both for munitions and fertilizers. Unless the Government plants are operated and fixation processes encouraged, two-thirds of our inorganic nitrogen must be imported in the near future.

University of Michigan,
Ann Arbor, Mich.

Sodium Fluoride as a Wood Preservative

Tests made years ago indicated that sodium fluoride might successfully be used as a wood preservative because it had high toxicity, was not injurious to metal and was convenient to handle. Laboratory tests alone, however, are never sufficient to establish the value of any material as a wood preservative; actual service tests, even though they require years to complete, are also needed.

In order to obtain comparative durability records, the laboratory in 1914 placed sap-pine ties treated with sodium fluoride, together with ties treated with zinc chloride and creosote, in one of the mines of the Tennessee Coal, Iron & Railway Co., at Birmingham, Ala. Similar service tests were also started at this time on red oak ties placed in the tracks of the Baltimore & Ohio R.R. Co.

After five years of service the mine ties which were treated with sodium fluoride have been found in as good condition as those treated with zinc chloride, both showing very little deterioration. The creosoted mine ties apparently were in still better condition, while the untreated ones were in various advanced stages of decay. The red-oak railway ties treated with sodium fluoride were practically all sound, as were those treated with zinc chloride, whereas a large percentage of the untreated oak ties had been removed.

Both of these tests, as well as others started later, must continue for a number of years yet before the relative value of the sodium-fluoride treatment for ties and timbers is definitely known.—*Abstract from Forest Products Laboratory "Technical Notes."*

Caustic Pot Settings

By F. G. Wheeler

THE process of making caustic soda and chlorine as a step in the manufacture of other compounds has become widespread in the last decade. In many of these the chlorine is used on the spot and the caustic soda is sold. The final operation before placing the caustic soda upon the market is its concentration from a sirupy solution to the fused condition which is accomplished by boiling it in a large open vessel or "caustic pot" until no more water remains in the liquid. In this condition the fused caustic soda is finished by heating red hot, and as it cools it is allowed to settle. When the freezing point is reached, it is conveyed to sheet-steel drums, in which it solidifies, and in this condition is shipped.

The "caustic pot" is a large semi-spherical vessel of cast iron. The common form is one in which the depth of the pot is about 70 per cent of the diameter. Various sizes are used, a common one weighing about thirteen tons and discharging from eighteen to twenty tons of caustic soda per batch. It is supported by a concrete column and is heated from a furnace using either coal, wood, gas or oil for fuel.

Furnace Requirements

The design of the furnace has never been standardized, each engineer using what seemed to him the best for the purpose. This practice has resulted in many different designs, for each one of which is claimed various advantages.

The chief objects in designing such a furnace, besides the obvious one of the ability to finish the caustic, are economy in operation, long life for both the furnace and the pot, an arrangement which will automatically enable an ordinary workman to finish the caustic, and finally, protection against severe damage to either furnace or setting in case of pot failure.

The first two requirements are readily obtained by following boiler-furnace practice. The art of building boiler furnaces has reached such a general high state of perfection, and the principles which govern it are so familiar to boiler operators, that a furnace adapted to caustic-pot operation can easily be designed.

Economical Conditions

Economy can best be obtained by securing high furnace temperatures. The simplest way of accomplishing this result is to build a furnace only large enough to finish the caustic when it is forced to work at a high rate of combustion per sq.ft. of grate surface. The fireman must then keep his grates covered and work a thin fire in order to make the pot boil and "finish" the caustic on time. The result is a high furnace temperature and consequent economy of operation. As with boiler furnaces, care must be exercised in not creating a furnace temperature so high that the ash, in the particular coal which is used, will form clinker and plug the grates, but as high a temperature as possible under local conditions should be maintained.

The second condition leading to economy is the arrangement of the ash pit. This should hold a small amount of water so that steam will be formed and will pass with the air through the grate, rotting the clinker and keeping the grates free. The use of shaking grates will assist materially in this work.

The third factor for economy is the use of a combustion chamber behind the grate, before the hot gases are chilled by the pot. This allows the soot to be burned and produces a minimum amount of smoke. It may be obtained by building a deep bridge wall behind the grates, which allows the necessary distance through which the flames may pass for combustion before reaching the pot. An extra convenience for the fireman, where coal is the fuel, is the arrangement of the bridge wall so that the fireman can place his fire upon it while cleaning the grates. The old fire can then be drawn forward to start the new fire without inconvenience.

The final consideration leading to economy is the arrangement of the flue around the pot. No hot gases should pass from the furnace to the stack without coming in contact with the pot. The flue should be narrow and arranged with baffles to direct and hold the gases close to the pot, and so prevent them from passing too quickly up the chimney.

The writer prefers a three-battery setting, using two fusing pots and a preheating pot. This arrangement causes gases to pass around the fusing pot and then into contact with a preheating or "back" pot which is set higher than the fusing pot. The liquor in the back pot is heated before flowing into the front pot. The flues around the back pot should also be baffled so that the gases from one fusing pot do not antagonize those from the other pot.

A few minor details make for economy, such as the use of a damper in the flue between the pots, the scraping of the fusing pot free from soot and ashes, and the cycle by which one pot of a battery is worked with the other one to keep the feed liquor from the back pot the hottest when needed.

Conditions for Low Furnace Depreciation

Long life of both the furnace and the pot is very essential in caustic finishing work. Long furnace life is obtained by using good brick and setting them properly. Only the best grade of firebrick should be used. These can be obtained in most shapes so that the furnace can be built for the hardest work and the highest temperatures. An arch made of wedge brick set on end gives the longest life. A semi-circular arch allows for expansion and contraction better than a sprung arch. Buckstays properly located permit the arch to expand and contract without injury to the side walls, and make the furnace a compact, well-built device for meeting the best operating conditions. In locating the furnace in front of the fusing pot, care shou'd be taken to prevent the working floor from resting on the arch or the side walls of the furnace. The weight and the vibration from anything passing over the floor should not be conveyed to the arch, which should be free to respond to furnace conditions only.

Conditions for Low Pot Depreciation

Long pot life is obtained by protecting it from any blow-torch effect of the flames as they leave the furnace. The thick cast-iron wall of the pot will not respond to the cooling from the liquor inside as a boiler tube does. By placing a firmly set guard wall at the back end of the bridge wall in front of the pot, the flames may be made to come in contact with the pot gradually so that they will do it no injury. The guard wall should be thin. A thick, heavy guard wall holds and reflects the heat back into the furnace and

does not adapt itself to expansion or contraction. The reflected heat warps the grates and the furnace door, as well as burns the fireman's hands. Such a wall will crack easily. It also occupies the space which should be used for combustion in the furnace. The guard wall should also be arranged to support the inner end of the arch which rests upon it.

The caustic pot should be arranged so that it can be turned easily from time to time and so present a fresh surface to the flames at the sides of the guard wall. A pot regularly turned about every thirty charges will have a long life without further attention.

Other Operating Hints

Only a few points remain for an engineer to bear in mind. Sufficient draft should always be available and the baffles should be arranged in such a way that the passage of the gases to the chimney are not excessively large. All that the fireman should have to do is to keep a good fire until the finishing heat is reached, when the damper can be closed and the pot allowed to cool slowly, permitting all of the impurities to settle out.

The bottom of the pot should be protected from the heat so that, as the settlings reach the bottom, no currents of molten caustic will carry the settlings back into the clear portions of the liquid. This can be done with the same material which protects the supporting column and which makes the flue floor by filling well up around the bottom of the pot.

If a failure occurs from a crack or a sand hole, it sometimes happens that the molten caustic will leak out, dissolve the cinder or the sand filling below the setting and work its way down and under the foundation. For this reason the writer prefers to place a slab of concrete under the entire battery rather than only the amount required for supporting the load. This concrete, if it be made of granite gravel, will present an effective barrier to the molten liquid, and will prevent it from destroying the support under the foundation.

Caustic furnaces and settings which have been built in the manner outlined above have eliminated many difficulties. The caustic soda can be finished regularly with less than 1,000 lb. of coal per ton of caustic. A furnace will last for fifty or more charges with no repairs, and many caustic pots now in service have poured more than two hundred batches of caustic soda.

The Caking of Sulphate of Ammonia*

By C. G. Atwater and J. F. W. Schulze

Sulphate of ammonia, as usually produced, has shown a tendency to cake when stored in bags or in a pile. This has been ordinarily attributed to the presence of 1 to 2 per cent moisture and to a small amount of residual sulphuric acid from the saturator. This caking tendency is of little importance when the material is used in mixed fertilizers, as the sulphate is easily broken up in the usual processes of handling and mixing. When sulphate of ammonia is to be used by itself, as a separate fertilizer or top dressing, as is the intention with the dried and screened article recently placed on the market, the mechanical condition is a critical point and any tendency to cake must, if possible, be eliminated.

The obvious method of preparation is to dry the salt in a current of hot air and to screen out small lumps and nodules. This method at first seemed to be effective and produced an article that was fine, dry and readily spread by hand or agricultural machines, providing the moisture was less than 0.25 per cent. As the manufacture extended to additional plants, however, it was found that the product of some of them when brought well below 0.25 per cent moisture, showed a lack of condition; would not run freely in a drill and was more liable to cake on storage. In order to determine the cause of this trouble and to eliminate it, the investigation which the present paper describes was made.

Laboratory Examinations

A number of representative samples of ammonium sulphate were collected and two selected for examination. No. 1 was chosen as typical of those that did not absorb moisture on standing and did not cake, and No. 2 as typical of those that remained moist to the touch and tended to cake.

*A paper read before the Fertilizer Section at the Philadelphia meeting, Sept. 2-6, 1919, and published by permission of the American Chemical Society.

In No. 2 some pyridine was present, this being noticeable by smelling of the hands after squeezing a handful. Pyridine was also detected in No. 1 in the same manner, but a markedly smaller amount was present.

Free Pyridine Bases

At first it was thought that free pyridine bases were the cause of the moisture in the samples, but this was disproved when pyridine dissolved in ether was mixed with some of the No. 1 material. After the evaporation of the ether, pyridine escaped from the sulphate till it was as dry as before the application.

Hot air was passed through a drying tower containing No. 2 sulphate and when this was exposed again to the air it still became moist and turned red.

Both No. 2 and No. 1 samples were now placed under pressure of 200 lb. per sq.in. for 24 hr., to see if caking were caused. In the case of the former a slight lumpy condition resulted, but the No. 1 sulphate was scarcely affected by the pressure.

The estimation of the pyridine present was undertaken by the following method: There was weighed out 25 g. of $(NH_4)_2SO_4$ into a liter round bottom flask, about

TABLE I. ANALYSES

	Total Bases Per Cent	Free Bases Per Cent
No. 2	0.281 0.275 0.276	0.162 0.192
No. 2 exposed to air	0.220 0.224	
No. 2 dried 9 hr. with hot air	0.148 0.150	0.098 0.112
No. 1	0.039 0.039	

250 c.c. of water added and when solution was complete 5 c.c. N NaOH was added. This was immediately connected to a flask containing NaBrO solution, thence leading through a splash bulb to a condenser. When the first flask was boiled, the NH_3 liberated was oxidized to nitrogen by the NaBrO, the pyridine passing through unchanged and being collected in N/10 H_2SO_4.

After considerable experimental work Congo red was

selected as the most suitable indicator for the titration with N/10 alkali. At the best the end point was very poor, and only by titrating back and forth several times could a fairly accurate end point be obtained.

The bases as they are liberated near the end point are partly insoluble in water and form a sort of emulsion which makes difficult an accurate determination.

The results in Table. I have been calculated on the basis of pure pyridine.

It is quite evident from the results on free bases that considerable hydrolysis of the pyridine sulphate takes place in solution. In each pair of analyses the second one was purposely boiled a little longer than the first and hence gave a higher result, as was to be expected.

Also even in the air pyridine is liberated from $(NH_4)_2SO_4$ samples, which are actually acid already. The method of testing the acidity of sulphate is simple titration with alkali. A large part, if not all, of this acidity is due to the presence of pyridine sulphate.

As an example of the degree of acidity that pyridine sulphate is capable of assuming, especially in heated solution, the following test stands out: To 25 c.c. N/10 H_2SO_4 was added an excess of light pyridine. This solution was allowed to evaporate on the steam bath until no distinct odor of pyridine was obtained. On diluting and adding Congo red it required about 15 c.c. N/10 NaOH to produce an alkaline reaction. The weakness of this base and the consequent hydrolysis of its salts in solution is also shown by adding an excess of it to a N/10 acid solution containing indicator. It will give a distinct acid reaction even in the presence of a large excess of pyridine over the theoretical amount required to react with the acid present. Only by the addition of an enormous excess can an alkaline reaction be shown with Congo red.

Miscellaneous Impurities

Qualitative tests were made on the two samples of sulphate, and besides the pyridine bases, iron and chlorine were found in small amounts. A small precipitate appeared with bromine water with the No. 2 sulphate. This was taken to indicate the presence of phenols, especially since a nitrophenol odor was produced on boiling with dilute HNO_3. $FeCl_3$, however, gave no color to the solution.

Since the No. 2 sulphate turned red in the air, contrary to the behavior of the No. 1, it was thought that phenols were the cause of this phenomenon. But when crude phenols in ether solution were mixed with No. 1 sulphate and the ether allowed to evaporate no red color appeared. The phenols slowly evaporated and left the sample as dry as before.

Some of the No. 2 sulphate was extracted with benzol and ether after removing the water present by boiling with benzol. A small amount of resinous material and some pyridine were found. After extracting at least twelve times and allowing to stand in the air, the sulphate again became moist and turned reddish brown. A sample of this was treated with dry NH_3 gas and remained dry on standing, with no color change.

It now occurred to us that pyridine sulphate might be the cause of the sample taking up moisture; so a small amount of H_2SO_4 was added to some No. 1 sulphate and a pyridine ether solution, stirred in until all the ether had evaporated. Then on standing in the air the material became moist and also assumed the reddish color of the exposed No. 2 sulphate.

Further, several samples of the No. 2 class of sulphate, including No. 2 itself, were treated with cold dry NH_3 gas and after a few minutes became quite dry to the touch, remaining so indefinitely in the air.

Pyridine[1] is likewise readily liberated from the $(NH_4)_2SO_4$ by washing the latter with saturated liquor containing a small amount of NH_3. When 250 g. of sulphate was washed with 150 c.c. solution containing about 0.3 g. NH_3, the pyridine content was reduced from 0.380 per cent in the original to 0.180 per cent in the final product. This is identical to the amount of pyridine in the ammonia gas-treated material.

From these results it is quite apparent that the cause of the moist feeling and consequently of the caking of $(NH_4)_2SO_4$ samples is pyridine sulphate, other impurities being negligible in effect.

Pyridine Sulphate the Cause of Caking

The impurity in $(NH_4)_2SO_4$ is therefore recognized as pyridine sulphate. This causes the sample to feel moist to the touch and due to its presence in the sulphate the latter will take up moisture on damp days, only to lose it later with the decreasing humidity of the atmosphere to produce a decided caking effect. The amount of water taken up, as well as the resultant caking, is in proportion to the amount of pyridine sulphate present.

By passing dry NH_3 gas through samples containing pyridine sulphate, pyridine is liberated and passes off. If the NH_3 is preheated, quicker and more thorough results are obtained. A treatment of the sulphate with very dilute ammonia liquor produces practically the same effect, and in some cases would be more practical commercially. Ammonium sulphate may be produced by either of these simple methods freed of a major part of its original pyridine content. In this state it will not absorb an appreciable amount of moisture from the air and its caking will be negligible.

The Barrett Co.,
New York, N. Y.

Truck With Regenerative Braking

After a number of years of research in the field of light-weight, low-cost electric vehicles, Dr. Charles P. Steinmetz has recently announced the development of a light-weight electric truck, one of the principal features of which is the method of motor control, which gives the motor compound characteristics by a storage cell floating on the field circuit.

The result of this method of control, Dr. Steinmetz pointed out, is speed maintenance, quick starting, power saving in the field at large currents and the feature of regeneration both on down grades and on stopping.

The field and armature of the motor revolve in opposite directions, each driving one of the car wheels. In this way motor weight is saved, the differential is eliminated and the truck is simpler and more compact.

By saving in motor weight and in battery weight, by the elimination of differential and in other ways a lower-weight truck is obtained. The ½-ton truck, without body, for instance, will have a weight, it is stated, of only 2,300 lb.

As a result of the above features and with the use of standard parts, it is claimed that lower operating cost and lower price will result.—*Electrical World*, vol. 75, p. 341, Feb. 7, 1920.

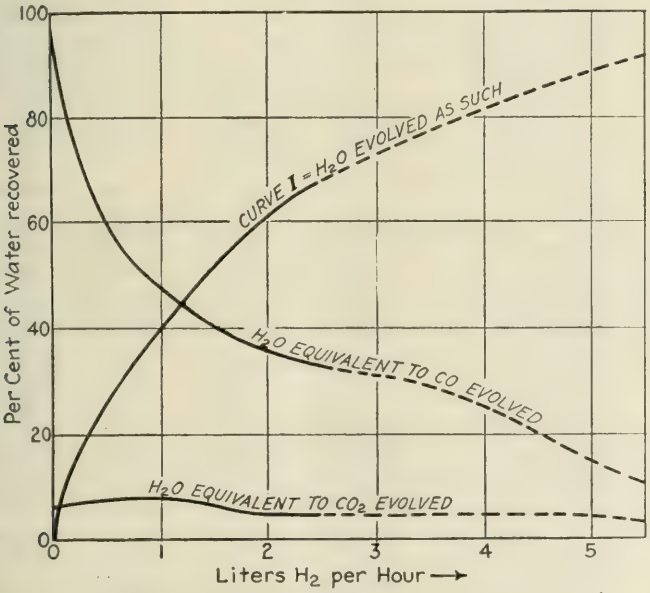
Synopsis of Recent Chemical and Metallurgical Literature

Limitations of Ledebur Method for Oxygen in Steel.—In Bureau of Standards Scientific Paper No. 346, J. R. CAIN and EARL PETTIJOHN present a study of oxygen content of Boylston's ingots (*Carnegie Scholarship Memoirs*, vol. 7, p. 102) and ingots of a series of bessemer rail-steel heats made at the Bethlehem Steel Co.'s Sparrows Point plant. In both of these studies acid converter metal was deoxidized by various substances, such as spiegel, ferromanganese, ferrosilicon, ferrotitanium and aluminum, and the oxygen content determined by the Ledebur method as modified by the authors (see Bureau of Standards Technologic Paper No. 118).

There seems to be no relationship between the Ledebur oxygen and various methods of deoxidation in the ladle, the aluminum treatment in the molds or the effect of rolling, the analytic results for steels of approximately the same chemical composition varying in a vague manner up to 0.020, sometimes approaching even 0.030. Ledebur oxygen, therefore, probably



GENERATION OF H_2O, CO AND CO_2 AT 900 DEG. C.

has no relation to efficiency of deoxidation, probably because the slag oxides resulting from the additions trapped in the solid metal do not yield their oxygen in this method. Neither is annealing *in vacuo* for a given time and temperature, nor determining nitride nitrogen adequate for a study of deoxidation.

In order to study the reasons for this failure on the part of the reputable Ledebur method, CAIN and L. ADLER (Bureau of Standards Scientific Paper No. 350) studied the various reactions which may proceed during the determination, i.e., when heating a steel (iron, carbon and iron oxide) to 900 deg. C. in a stream of hydrogen of various speeds. Using a mixture of iron oxide and graphite, all the oxygen in the ore could be recovered as water.

That is, the reaction

$$FeO + H_2 = Fe_2 + H_2O$$

proceeds practically to completion without interference by $FeO + C \longrightarrow Fe + CO$ which Falcke says starts at about 600 deg. C.

However, when a mixture of iron oxide and cemented iron or cast iron was heated under a given gas stream, the amount of oxygen recovered as water fell off as the amount of iron-carbon alloy increased; that is, iron carbide has now partially reduced iron oxide. On studying a mixture which contained a ratio of ferrous oxide to combined carbon as 1 is to 5 (which was thought to approach extreme conditions occasionally found in steels) and varying the rate of hydrogen current, results plotted in the accompanying figure were found.

Since curve I showed such a large deficit in oxygen as water, additional studies were made in order to determine whether the other gases were CO, CO_2, and saturated hydrocarbons. The last proved to be very small, while the carbon oxides are plotted in the figure.

Reactions $FeO + C \leftrightarrows Fe + CO$

and $FeO + CO \leftrightarrows Fe + CO_2$

should tend to produce larger amounts of CO with increasing hydrogen rate, but since this condition was not found experimentally, it is thought that these reactions are not much affected at 900 deg. C. Thermal dissociation of carbon monoxide

$$2CO \leftrightarrows CO_2 + C$$

should be shifted to the left with more rapid hydrogen passage. A result in conformity to that found

$$CO_2 + H_2 \leftrightarrows CO + H_2O$$

tends toward the right at 900 deg., so a rapid current by sweeping quickly into a cool spot will suppress production of CO. Reaction

$$C + H_2O \leftrightarrows CO + H_2$$

is the one most affected, being shifted to the left, according to expectations. The figure shows that under the experimental conditions holding for Ledebur's method no more than 75 per cent of the reduction of ferrous oxide can be affected by hydrogen (temperature, 900 deg. C., carbon : ferrous oxide = 5 : 1; and hydrogen rate 3 liters per hr.)

Switzerland Factory Statistics in 1918.—The report of the Swiss Department of Public Economy published in the November, 1919, issue of the *Swiss Exporter* gives the statistics for the number of factories and employees in Switzerland in 1918, arranged according to industries. There were 9,327 establishments and 381,170 employees working under the factory acts. The figures for the various industries are as follows:

Industry	No. of Establishments	Employees — Male	Employees — Female	Total
Cotton	313	8,585	17,458	26,043
Silk	211	6,788	23,478	30,266
Wool	66	2,585	4,111	6,696
Linen	31	411	945	1,356
Embroidery	828	7,932	14,923	22,855
Other textile industries	129	1,430	3,183	4,563
Clothing and outfitting	1,031	11,279	24,890	36,169
Foods and table luxuries	791	13,573	13,614	27,187
Chemical industries	270	14,230	3,534	17,764
Power stations	276	4,705	8	4,713
Paper	700	12,798	6,105	18,903
Woodworking	1,325	21,954	910	22,864
Metals	902	30,961	5,582	36,543
Machinery	842	61,986	3,817	65,803
Watches and jewelry	1,222	25,376	21,099	46,475
Mineral materials	390	11,817	1,153	12,970
Total	9,327	236,410	144,760	381,170

From 1913 to 1918 the number of factory employees has gone up from 341,295 to 381,170, an increase of about 40,000; the increase is most notable in the machine, metal, watch and chemical industries. There has been a decrease in the number of employees in the

textile, paper, wood, food and mineral industries. In 1918 39 per cent of all factory employees in Switzerland were employed in the machine, watch, jewelry and metal industries; of the total number 38 per cent were females.

Acid-Resisting Metals.—The December, 1919, issue of *Chemie et Industrie* contains an extensive description of acid-resisting metals by Prof. C. MATIGNON. With the exception of a short description of ferroborides, the article treats of ferrosilicons. He gives their historic beginning with the work of Jouve, enumerates the different alloys used for acid-resisting containers used in France, Germany, Great Britain and America, and describes their properties (fusibility, density, conductivity, magnetism and chemical resistance). The study of the chemical resistance of the industrial ferrosilicons was made in collaboration with Miss Momal. They studied the action of nitric acid and the mixture of acetic and butyric acid on Metillure, Elianite I, Elianite II, Ironac, Duriron and Tantiron, for different periods of boiling. The results are tabulated. The article contains also a review of the uses of some of the alloys in the manufacture of apparatus for the heavy chemical industry.

Influence of Chemical Composition and Thermal Treatment Upon the Properties of Iron Alloys.—E. GUMLICH and P. GOERENS publish in the *Elektrotechnische Zeitschrift* of June 26, July 3, 10, 17 and 24, 1919, their report upon the results of experimental investigations into the properties of pure iron alloys which have been carried out in Germany for ten years or so under the co-operation of several scientific institutions and metallurgical concerns. Most of the measurements were made at the Reichsanstalt, hand in hand with metallographical studies conducted by WÜST and GOERENS. Suitable samples with systematically varying percentages of C, Si, Al and Mn were carried through certain thermal and magnetical cycles, and extensive sets of data for each condition of the material were obtained. By extrapolation from the curves for the several series of alloys there were obtained, as probable averages, the following data for pure iron: Specific gravity, 7,876 g. per cu.cm.; specific resistivity, 0.0994 ohm per min., sq.mm. at 20 deg. C.; temperature coefficient, 0.00573 per 1 deg. C.; magnetic saturation, 21,620 max. per cu.cm. The effects of annealing upon the magnetic properties of commercial transformer plate were thoroughly investigated, the results leading to the conclusion that the annealing causes a decided deterioration, the effect being worse the higher the temperature. During the first few hours, however, a net improvement is obtained, due to mechanical softening of the material and expulsion of gases, and the effects preponderate over the deterioration due to the annealing. Maximum improvement was observed in from 4 to 24 hr., and 785 deg. C. (1,440 deg. F.) appeared to be the most favorable annealing temperature.

Japan's Foreign Trade.—The January, 1920, issue of the *Trans-Pacific* gives, in statistical form, the quantity and value of the principal commodities imported and exported during the first nine months of 1919. Figures for the corresponding period of 1918 are given for comparison. Tables I and II present a summary of the figures given for products of interest to the chemical and metallurgical industries.

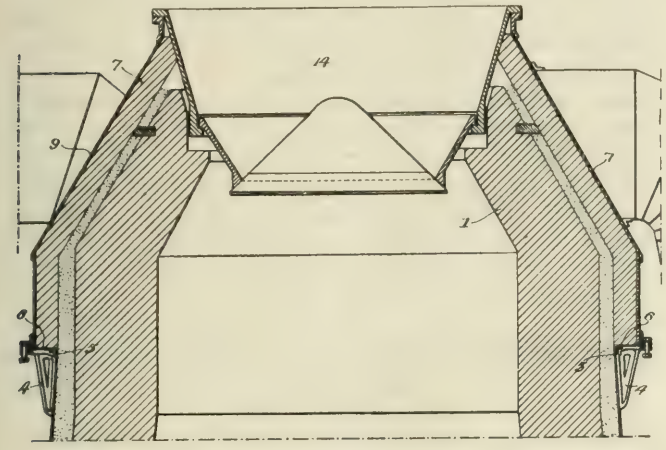
Recent Chemical and Metallurgical Patents

Complete specifications of any of the United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Blast-Furnace Top.—EDWIN G. RUST, of Philadelphia, Pa., has patented the blast-furnace top shown in the figure, so designed that the main furnace lining 1 is carried full height at maximum thickness, and the dome lining is supported entirely outside of the shell, being supported by brackets 4 and angle iron 5



BLAST-FURNACE TOP

riveted to the steel plate. Horizontal ring 6 is riveted to angle iron 5, but held down to the brackets only by loose bolts, so that thermal expansions and contractions may be reflected by a limited vertical movement of the outer part of the ring, the dome lining 7 and the hopper 14, all acting as a unit. (1,307,884; June 24, 1919.)

Rust Prevention.—JAMES H. GRAVELL, of New York City, notes that it is difficult to remove the last traces of the liquid, non-volatile phosphoric acid in which steel parts are immersed for rust proofing. Especially is it necessary to remove the last traces when the rust-proofed pieces are to be painted. He suggests that a saturated solution of oxalic acid in water be used instead. The pieces upon drying are then covered with finest crystals of solid acid, over which paint can be placed with no damage to its adherent qualities or permanency. In case oily metal is to be treated, 30 per cent by volume of an organic solvent such as alcohol is added to the bath. (1,315,017; Sept. 2, 1919.)

Sodium Ferrocyanide.—When a mixture of one part of coke with four parts of barium carbonate is heated in a suitable retort for about 6 hr. while a current of nitrogen is passed through the mass, the product obtained has approximately the following composition: $Ba(CN)_2$, 25 per cent; $BaCN_2$, 3; BaO, 23; $BaCO_3$, 35; C, 14. After grinding, the material is leached with hot water, yielding a solution of cyanide, cyanimide and hydroxide of barium. Treatment with sodium carbonate precipitates the barium as carbonate and forms the corresponding sodium salts. The cyanide is changed into ferrocyanide by heating the solution to 80 deg. C. with finely divided iron, and the hydroxide converted to carbonate by passing in carbon dioxide. In order to separate the sodium carbonate and sodium ferrocyanide by fractional crystallization, TEOFRON BOBERG, of London, England, takes advantage of the fact that the maximum solubility of sodium carbonate is coincident with the transition point at about 36 deg. C. Accordingly, the solution is evaporated to incipient crystallization at 80 deg. C., and then cooled to about 36 deg. C., when the ferrocyanide separates substantially free from carbonate. The mother liquor when cooled further gives crystals of sodium carbonate which are used again in the process. (1,318,258; assigned to Techno-Chemical Laboratories, Ltd., London, England; Oct. 7, 1919.)

Bismuth.—Concentrates containing 80 to 95 per cent of bismuth, with varying amounts of sulphur and tellurium, are heated to about 1,700 deg. F. A portion of the S and Te volatilizes, while a slag forms which may be stripped by cooling to about 1,200 deg. F. On reheating, the presence of S and Te is indicated by a purple tint on the surface of the molten metal. These impurities may be removed by treating with 5 to 10 per cent of $CaCl_2$ or $MgCl_2$. The chlorine volatilizes iron impurities, while the calcium or magnesium combines with the S or Te. (1,318,335; ELTON R. DARLING, assignor to Ellis-Foster Co.; Oct. 7, 1919.)

Sodium From Sodium Chloride and Calcium Carbide.—At temperatures between 1,200 and 1,300 deg. C. a mixture of calcium carbide and sodium chloride gives off vapors of metallic sodium which may be recovered in a suitable condenser. According to HORACE FREEMAN, of Niagara Falls, Ont., the reaction probably proceeds in two stages:

$$2NaCl + CaC_2 = CaCl_2 + Na_2C_2$$
$$Na_2C_2 + \text{heat} = 2Na + 2C$$

Obviously, other alkali metals may be made by the same process. (1,319,148; assigned to American Cyanamid Co.; Oct. 21, 1919.)

Oxidation of Methane to Formaldehyde.—Natural gas or other gas with high CH_4 content is mixed with two volumes of nitric oxide and a volume of air or oxygen sufficient to convert the nitric oxide into nitrogen peroxide. The gaseous mixture is then passed through a red hot porcelain tube. In order to prevent further decomposition or oxidation of the formaldehyde formed, REGINALD K. BAILEY, of Lawrence, Kan., suggests the following procedures: (*a*) The gases are quickly cooled by passing through water containing $CaCO_3$ in suspension. The $CaCO_3$ tends to unite with the oxides of nitrogen, except nitric oxide, thus preventing the formation of nitric acid; (*b*) the hot gases may be passed over a dehydrating agent such as CaO, whereby the water formed during the reaction is absorbed and the formation of nitric acid or nitrous acid prevented. Were these acids permitted to form, they would oxidize the formaldehyde to carbon dioxide and water. (1,319,748; Oct. 28, 1919.)

Use of Niter Cake in Diazotization.—Niter cake (sodium bisulphate) furnishes a cheap source of acid for the liberation of nitrous acid from sodium nitrite in the process of diazotization. In addition, the sodium sulphate formed acts as a precipitant for the compound formed after coupling. ELMER K. BOLTON, of Wilmington, Del., cites the following example of this use for niter cake: Aniline (60 g.) is converted into aniline sulphate by the addition of 51.3 g. of niter cake, showing, on analysis, 35 per cent acidity measured as sulphuric acid, and 22.3 g. of sodium nitrite is then added so as to diazotize the aniline sulphate,

which then becomes coupled with the excess of aniline to produce diazoamidobenzene, which separates out quantitatively and immediately from the water solution. (1,320,443; assigned to E. I. du Pont de Nemours & Co.; Nov. 4, 1919.)

Barium Nitrate From Barium Sulphide.—The conversion of alkaline earth sulphides into nitrates is conveniently accomplished by double decomposition with nitrates of metals whose sulphides are not stable in water solution, being hydrolyzed with the formation of H_2S and the hydroxide of the metal used. Nitrates of aluminum, magnesium and chromium are specifically mentioned by ROBERT W. DAVIS, JR., of Jenkintown, Pa. Using aluminum nitrate, the reaction which takes place at the boiling point of the solution may be written:

$$3BaS + 2Al(NO_3)_3 + 6H_2O = 3Ba(NO_3)_2 + 2Al(OH)_3 + 3H_2S$$

The aluminum hydroxide, being insoluble and in a flocculent form, is easily filtered off, so that a pure solution of barium nitrate is obtained. (1,321,013; Nov. 4, 1919.)

Precipitating Anthranilic Acid From Aqueous Solutions.—The sodium salt of anthranilic acid is ordinarily made by treating phthalimide with sodium hypochlorite and sodium hydroxide in accordance with the equation:

$$C_6H_4\begin{matrix}CO\\CO\end{matrix}NH + NaOCl + 3NaOH = C_6H_4\begin{matrix}COONa\\NH_2\end{matrix} + Na_2CO_3 + NaCl + H_2O$$

In attempting to precipitate anthranilic acid from the solution by means of HCl or H_2SO_4, difficulty is experienced in determining the correct amount of acid to use, since an insufficient amount will fail to precipitate all of the anthranilic acid, while an excess will result in the formation of the water-soluble hydro chloride (or sulphate) of anthranilic acid. During the process of acidification, the sodium carbonate is converted into chloride or sulphate. These sources of loss are remedied by RALPH S. POTTER, of Grantwood, N. J., in the following manner. The solution is first treated with CO_2, whereby at least 50 per cent of the sodium present as Na_2CO_3 is recovered as bicarbonate. The anthranilic acid is now precipitated by an acid which is too weak to form a salt with it, such as H_2SO_3, so then an excess has no harmful effect on the yield. (1,322,052; assigned to The Barrett Co.; Nov. 18, 1919.)

Treating Black Liquor From Sulphate Pulp.—The alkali losses incurred in the treatment of black liquor and in the preceding pulp-manufacturing process are usually compensated by the addition of salt cake to the black ash before calcination. The sulphate is reduced to sulphide during the latter operation. The carbonate which is also formed must be causticized by treatment with lime before it can be used in the digester. ELIS OLSSON, of East Angus, Que., proposes the substitution of niter cake for salt cake, thereby converting the carbonate into sulphate and avoiding the use of lime. The cooking liquor prepared from this product will contain sodium sulphide as the active agent. (1,322,043; Nov. 18, 1919.)

Purification of Iodine.—Certain impurities present in commercial iodine, such as iron iodide, iodine chloride and iodine bromide, cannot be removed by the process of sublimation. RAY M. CARTER, of Baltimore, Md., has patented the following method of purification: 200 lb. commercial iodine and a solution of 10 lb. KI in 100 lb. water are placed in a kettle, and steam is introduced through a perforated coil in the bottom. The steam decomposes the impurities referred to, liberating the iodine. The iodine vapors (mixed with steam) are condensed and the wet iodine dried at room temperature under a vacuum of 28 in. of mercury. (1,324,761; assigned to U. S. Industrial Alcohol Co.; Dec. 9, 1919.)

Anthraquinone and Phthalic Anhydride by Catalytic Oxidation.—CHESTER E. ANDREWS, of Pittsburgh, Pa., has found that aromatic hydrocarbons containing side chains or more than one ring may be oxidized by boiling with sulphuric acid in the presence of oxides of molybdenum or vanadium. Oxidizing agents such as sodium dichromate or manganese dioxide may be used, and the catalytic effect of the molybdenum or vanadium oxide is increased in many instances by the admixture of compounds or oxides of metals of the fifth or sixth group of the periodic system. Anthracene and ortho-xylene when treated in this manner, using 50 per cent H_2SO_4, yield anthraquinone and phthalic anhydride respectively. (1,324,715; assigned to the Selden Co.; Dec. 9, 1919.)

Personal

ROY N. BUELL will leave Battle Creek, Mich., the end of February to build a powdered lignite fuel plant in Melbourne, Australia.

G. M. BUTLER, director of the Arizona Bureau of Mines and dean of the College of Mines and Engineering, has been elected to head the Chamber of Commerce, Tucson, Ariz., for the coming year.

E. W. ENGELMANN has been appointed to the position of consulting research engineer for the Utah Copper, Chino Copper, Ray Consolidated Copper and Nevada Consolidated Copper companies, with headquarters in Salt Lake City.

ARTHUR G. HENRY, metallurgist for the Illinois Tool Works and secretary of the American Steel Treaters' Society, has resigned to become Chicago representative of the Vanadium Alloys Steel Co.

Dr. E. H. LESLIE has resigned from his position as assistant to the president and to the general manager of the U. S. Industrial Alcohol Co. of New York City and has accepted a position as associate professor of chemical engineering at the University of Michigan, Ann Arbor, Mich.

ALEXANDER MACKAY, president of the Dundee-Arizona Copper Co., with his son, Captain F. B. MACKAY, both of Dundee, Scotland, have made an inspection of the property of the company at Jerome, Ariz.

Dr. E. S. MERRIAM has resigned the professorship of chemistry of Marietta College to accept the position of chief chemist for the Safe-Cabinet Co., Marietta, Ohio.

R. B. MOORE, chief chemist, U. S. Bureau of Mines, was in Golden, Col., during the latter part of January in connection with the co-operative work on oil investigations undertaken by the State of Colorado and the Bureau of Mines.

R. A. ROSS, a member of the Administrative Commission of the City of Montreal, has been elected president of the Engineering Institute of Canada.

E. E. THUM, associate editor of CHEMICAL & METALLURGICAL ENGINEERING, spoke Wednesday evening, Feb. 18, on "The Effect of Phosphorus and Sulphur in Steel" under the auspices of the American Steel Treaters' Society at the Bush Terminal Bldg., New York.

HENRY E. WOOD, formerly of Denver, Col., who has been living in New York for the past year or two, has gone to Freeport, La., for a few months.

Obituary

Dr. David S. Pratt, formerly assistant director of the Mellon Institute of Industrial Research of the University of Pittsburgh, died in St. Louis, Mo., on Jan. 28, after a short illness from pneumonia. He was a member of the American Chemical Society and of the following fraternities: Phi Kappa Sigma, Sigma Xi, Alpha Chi Sigma, and Phi Lambda Upsilon.

David Shepard Pratt was born in Towanda, Pa., on Sept. 20, 1885, the son of Charles Manville and Louise Hale (Woodford) Pratt. Following the completion of the collegiate course at Cornell University (A.B., 1908), he was appointed a Fellow in Chemistry at that institution (1909-1911) and in 1911 he received the degree of Ph.D. Dr. Pratt then joined the staff of the Bureau of Chemistry, Washington, D. C., as assistant chemist, but shortly afterward was selected as chief of the Organic Division of the Bureau of Science in Manila, P. I., where he spent three productive years in chemical research and as a member of the Pure Food and Drug Board. In 1914 he decided to return to the States and accepted a professorship of chemistry at the University of Pittsburgh. Dr. Pratt occupied that chair and the headship of the organic department of the School of Chemistry at "Pitt" from 1914 to 1917, in which year he was made an assistant director of the Mellon Institute of Industrial Research. On Jan. 1, 1920, Dr. Pratt resigned at the Institute and was arranging to enter consulting chemical practice in St. Louis, Mo., at the time of his fatal illness.

Dr. Pratt was known principally for his published investigations on phthalic acid derivatives, but his reports of researches on various problems in the domain of tropical chemistry have also been of importance and he was a recognized authority on chemical Philippiniana. At the Mellon Institute Dr. Pratt enjoyed broad opportunities to apply, in the inquiries of the Industrial Fellowships under his supervision, his splendid equipment in chemistry and many results of technical importance were obtained through his suggestive aid. His profound knowledge of pure organic chemistry and his familiarity with research methods were respected by his associates and played a prominent part in establishing the high success of the system in operation at the Institute. His departure to enter professional practice was sincerely regretted by all of the members of the institution. Dr. Pratt resided in St. Louis at 38 Portland Pl. He is survived by his wife, Fredonia Elizabeth (Johnson) Pratt, and an infant son, David Shepard Pratt, Jr.

Current Market Reports

The Non-Ferrous Metal Market

New York, Feb. 20, 1920.—The copper market continues dull. Lead, zinc and tin have strengthened.

	Cents per Lb.
Copper, electrolytic	19.00
Aluminum, 98 to 99 per cent	33.00
Antimony, wholesale lots	11.25
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	60.00
Lead, New York, spot	9.00
Lead, E. St. Louis, spot	8.37½
Zinc, spot, New York	9.50
Zinc, spot, E. St. Louis	9.22½
Silver (Dollars per oz.)	1.32¼

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	27.50
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	33.50
Seamless bronze tubing	34.50
Seamless brass tubing	30.50

RARER METALS

Cadmium	lb.	$1.50
Cobalt	lb.	1.50
Platinum	oz.	150.00
Iridium	oz.	250.00
Palladium	oz.	150.00
Mercury	75 lb.	85.00

SCRAP METALS

	Cents per Lb.
Aluminum, cast scrap	23½@24½
Aluminum, sheet scrap	22½@23½
Aluminum clippings	25½@27
Copper, heavy machinery comp	14½@14¾
Copper, heavy and wire	13½@14
Copper, light and bottoms	12½@12¾
Copper, heavy cut and crucible	15½@16
Brass, heavy	7¼@ 8¼
Brass, casting	10¼@10¾
Brass, light	5¼@ 6¼
No. 1 clean brass turnings	8¼@ 8¾
No. 1 comp. turnings	12 @12½
Lead, tea	5¼@ 5½
Lead, heavy	6½@ 7
Zinc, scrap	4½@ 4¾

Chemical and Allied Industrial Markets

New York, February 20, 1920.

Advancing prices among the heavy chemicals due to a low supply in some lines is the report of the week. Delivery on contracts has been held up by the recent storm, which, added to the car shortage, has caused considerable anxiety among the trade. Exporting has fallen off slightly owing to the abnormal rate of exchange and the great difficulty of obtaining shipments.

General Chemicals

Barium chloride has been active, with very little material to be found on the spot market. Quotations as high as $140@$150 per ton are reported, but the average price varied from $90@$110 per ton. A sudden stop in supplies has caused a jump in *bichromate of soda* to 33c. per lb. Producers ran short of coal, which, combined with the crippling of transportation, left the market empty. The price quoted on this item last week was from 21@23c. per lb. Exporting of *caustic soda* has been affected by the rate of exchange, and until this situation is relieved conditions will remain unsettled. Sales have been reported at $4.60 per cwt., while the prevailing price seems to be around $4.50 per cwt. *Soda ash* has also felt the drop in the money market, but producers are so completely sold out that this will hardly lessen the pressure. The average quotation on domestic light is about $2.25 per cwt., while $2.35 is the listing for foreign. *Formaldehyde* is practically unobtainable. The quotation of 52@55c. per lb. is the average for what small lots are changing hands. The increasing shortage on *bleaching powder* has advanced the price to $3.50 per cwt., while $4@$4.50 is being asked for small quantities on spot. The scarcity in the *ammonia* products has held this branch of the market firm, with very few shipments reported during the week.

Coal-Tar Products

This market remains practically unchanged. Large producers are withdrawing a number of items from their list of products due to the inability to meet the demand. Lack of raw materials and disadvantage of small plant facilities are accountable for this situation. Many firms are completely sold out and are having difficulty meeting contracts. The recent transportation tie-up has also affected this industry seriously. *Dimethylaniline* is the center of this group. Small quantities are to be had, but the report from producers is that they are all sold out. The average quotation is around $1 per lb., while $1.20 has been reported on some sales. *Phthalic anhydride* remains quiet at quotations varying from 50@80c. per lb. One large producer who has been out of the market for some time past is working on a process to produce a better grade than average market material at a cheaper price.

Naval Stores

Another drop in all grades of *rosin* has been caused by the falling off of export inquiry. The rate of exchange is directly accountable for this situation, and it is the opinion of many that the market will continue dull until more

favorable conditions arise. *Spirits of turpentine* is easier at $1.93@$1.95 per gal., with plenty of material on the domestic market.

Crude Rubber

The steady drop in this market has tempted buyers to invest for more than their present needs and as it seems they are waiting for more stable conditions. This field is probably feeling the drop in sterling more than any other market. *Para, up-river fine,* is quoted at 44c. per lb., while *caucho ball* is listed at 33½c. per lb. *First latex crepe* dropped to 48c. and *amber crepe* No. 1 is going at 45c. per lb.

The Iron and Steel Market

Pittsburgh, Pa., February 19, 1920.

Indications have increased that if the steel industry is able to operate at a fairly full rate and is able to ship its products there will be no acute scarcity of steel. There has been much opinion expressed in the past few weeks contrary to this view. Some of it has been expressed chiefly for the purpose of furnishing an argument for advancing selling prices of steel products. Buyers of steel have been equally responsible for views that there would not be enough steel to meet all requirements, since they have been free in the bidding of premium prices for early deliveries.

It is a very favorable circumstance that despite car shortages, affecting steel production in various ways, and despite predictions that there would be a short supply of labor for several months, with inefficiency, the production of steel has increased steadily, until it is now at a rate of nearly 90 per cent of capacity.

Coke Production Increasing

There has been no material change in the car supply in the Connellsville coke region for several weeks, the production having been practically uniform since the week ended Dec. 27, which was one of light production, on account of the holiday. Coke production at byproduct ovens, on the other hand, has increased rather steadily, as better coal supplies have been received, and this week further improvement is reported in this respect. Byproduct coke production is not yet up to normal at all points, but it is at a much better rate than one month or two months ago, and several individual plants are reported as being in full operation, with all ovens on and at normal coking time.

Shipping Finished Product

At nearly all steel mills car supplies for shipping finished product have proved more or less inadequate. Traffic managers have been very busy endeavoring to secure additional cars, and have had considerable success, though such success is never permanent, involving merely an additional supply of cars for a time, not a permanent increase in the trade. The quantity of finished steel lying at mills and awaiting shipment is very large, but has hardly increased in the aggregate in the past week or two. There has been little if any actual curtailment in steel production owing to finished material backing up against the rolls, a development that was feared and one that is not for a certainty forestalled even now. By as much as the supply of steel in the hands of jobbers and manufacturing consumers has been curtailed by the failure of steel produced to move to destination, by so much will there be extra supplies when the steel eventually is shipped.

Higher Steel Prices

The United States Steel Corporation continues to adhere to the March 21 or Industrial Board prices, and accordingly its entire product is taken up by regular customers so that there is no material left to offer to the customers of other mills, or to chance buyers. Among the independents, two large interests have committed themselves to the policy of taking care of regular customers at prices, except in the case of wire products, approximately equal to those ruling before the March 21 reductions, but one at least of these independents is quite ready to charge casual buyers, not regular customers, much higher prices when the buyer is willing to pay such prices, for early delivery. Among other mills various policies are pursued, the more common one being to stay almost entirely out of the market. Thus, while it is very hard to buy steel, there is also a condition of many of the mills not being sold far ahead by any means.

No Definite Price List

There is no definite list of prices now representing the steel market, as forward deliveries are unusual, and prompt deliveries vary in price according to time of delivery and tonnage. Prices on the whole are higher than a week or two ago, and the market in general seems to be in process of a runaway. Plates for anything like early delivery are now 3.75@4c. Bars are 3.50@4c. Dealers in oil well supplies have bid 3.50c. freely for "augur stems," representing a particularly economical form of steel bar to roll.

Sheets are selling at a very wide range of prices. While a chance buyer could not secure any black sheets at 4.50c., there has been some business done by mills with regular customers at this figure, $3 a ton above the March 21 price. More tonnage is moving at 4.65c. and still more at 5c., while small lots are bringing 6c., 6.50c. and 7c. In all cases the lower priced sales are to regular customers of the mills, while the highest priced transactions are with jobbers or speculators who have an opportunity to turn the material over at a profit. Blue annealed sheets have sold at 4.50c. in a moderate way, the March 21 price being 3.55c., while sales of some volume have been made at 5c. and even at 5.50c. Galvanized sheets are selling similarly at 6@8c., the March 21 price being 5.70c.

Wire nails for early delivery and regular mill lots are fairly well established at $4.25 per keg, base. The March 21 price, still adhered to by the American Steel & Wire Co., was $3.25, while the war control price was $3.50.

Pig Iron

The pig iron markets have continued to move upward, there being urgent buying pressure on the part of a few consumers, while producers have been very reserved about selling. In the past few weeks there has been practically nothing but second half iron to sell, and as furnaces regarded sales for that delivery as "backlog business" they have been indisposed to sell more than, say, one-third of their product at the opening prices. In the past two or three days there have been some signs of there being less buying pressure, and in some quarters, even among producers, predictions are now being made that present prices will be found to represent the top level on this movement. Seeing that they are far above the war-time prices and are more than two and one-half times the 10-yr. pre-war average of pig-iron prices, predictions that the advance has stopped cannot be regarded as wholly unreasonable. It is a fact well attested in history that all price advances have stopped at one time or another.

The valley market now stands at $42 for bessemer, $43 for basic and $42 for foundry. Basic had trailed far behind foundry, but took a sudden spurt last week. The Philadelphia market stands at $46.35, delivered, for No. 2X, Buffalo being $44.25 for No. 2X. Cleveland is about $42 for foundry iron, and Chicago $43. The Birmingham market remains at $40, with offerings rather light at the figure.

Ferro-Alloys

Domestic makers of ferromanganese seem to be well sold up for the half year, while for the second half they are selling only in a limited way at their recently advanced price of $160, delivered, for 76 to 80 per cent alloy. English is quoted at $150 c.i.f. Spiegeleisen is quoted at $56 to $57, furnace, for 19 to 21 per cent.

Electrolytic ferrosilicon is quiet at $80 for 50 per cent and $140 for 75 per cent, delivered Pittsburgh, valleys and Cleveland. Bessemer ferrosilicon is quoted at $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent f.o.b. Jackson, Ohio.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	.....	$0.60 – $0.65

Hydrofluoric, 52 per cent	lb.	.12 – .12½	.14 – .....
Lactic, 44 per cent tech	lb.	.11 – .11½	.12 – .16
Lactic, 22 per cent tech	lb.	.05 – .06	.05½ – .07
Molybdic, C. P	lb.	.....	4.25 – 5.00
Nitric, 40 deg	lb.	.06 – .07	.07½ – .08½
Nitric, 42 deg	lb.	.06½ – .07	.08 – .09½
Oxalic, crystals	lb.	.35 – .40	.40 – .45
Phosphoric, Ortho, 50 per cent solution	lb.	.24 –	.....
Picric	lb.	.30 – .35	.40 – .50
Pyrogallic, resublimed	lb.	2.50 – 2.55	2.60 – 2.65
Sulphuric, 60 deg., tank cars	ton	17.50 – 22.00	.....
Sulphuric, 60 deg., drums	ton	.....	.....
Sulphuric, 66 deg., tank cars	ton	22.00 – 25.00	.....
Sulphuric, 66 deg., drums	ton	.....	.....
Sulphuric, 66 deg., carboys	ton	.....	.....
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	27.00 – 30.00	32.00 – .....
Sulphuric, fuming, 20 per cent (oleum) drums	ton	32.00 –	34.00 – .....
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	35.00 –	40.00 – .....
Tannic, U. S. P	lb.	.....	1.35 – 1.45
Tannic (tech.)	lb.	.....	.42 – .55
Tartaric, crystals	lb.	.....	.69 – .74
Tungstic, per lb. of WO	lb.	.....	1.20 – 1.40
*Alcohol, Ethyl	gal.	4.80 – 5.50	6.00 – 7.00
*Alcohol, Methyl	gal.	1.50 –	1.52 – 1.57
*Alcohol, denatured, 188 proof	gal.	.....	.65 – .78
*Alcohol, denatured, 190 proof	gal.	.....	.67 – .74
Alum, ammonia lump	lb.	.04½ – .05	.05½ – .06
Alum, potash lump	lb.	.08 – .08½	.09 – .09½
Alum, chrome lump	lb.	.15 – .16	.18 – .20
Aluminum sulphate, commercial	lb.	.01½ – .02	.02½ – .02½
Aluminum sulphate, iron free	lb.	.02½ – .03	.03½ – .03½
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.08¼ – .10¾	.11 – .12
Ammonia, anhydrous, cylinders (100-150 lb.)	lb.	.33 – .35	.35 – .37
Ammonium carbonate, powder	lb.	.13 – .16½	.17 – .17½
Ammonium chloride, granular (white salammoniac)	lb.	.14 – .15	.16 – .17½
Ammonium chloride, granular (gray salammoniac)	lb.	.13 – .13½	.14 – .14½
Ammonium nitrate	lb.	.10 – .12	.....
Ammonium sulphate	lb.	.05 –	.06 – .....
Amylacetate	gal.	.....	3.65 – 3.75
Arsenic, oxide, lumps (white arsenic)	lb.	.....	.10½ – .11
Arsenic, sulphide, powdered (red arsenic)	lb.	.23 – .24	.....
Barium chloride	ton	85.00 – 95.00	100.00 – 110.00
Barium dioxide (peroxide)	lb.	.26 – .27	.28 – .30
Barium nitrate	lb.	.11 – .12	.13 – .14
Barium sulphate (precip.) (blanc fixe)	lb.	.03 – .03½	.03½ – .04
Bleaching powder (see calcium hypochlorite)		.....	.....
Blue vitriol (see copper sulphate)		.....	.....
Borax (see sodium borate)		.....	.....
Brimstone (see sulphur, roll)		.....	.....
Bromine	lb.	.90 – .95	.....
Calcium acetate	cwt.	2.00 – 2.05	2.10 – .....
Calcium carbide	lb.	.....	.04¾ – .05
Calcium chloride, fused, lump	ton	20.00 – 25.00	30.00 – 40.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02¼
Calcium hypochlorite (bleaching powder)	cwt.	..... – 3.50	4.00 – 4.50
Calcium peroxide	lb.	.....	1.50 – 1.70
Calcium phosphate, monobasic	lb.	.....	.75 – .80
Calcium sulphate, pure	lb.	.....	.25 – .30
Carbon bisulphide	lb.	.06 – .08	.09 – .10
Carbon tetrachloride, drums	lb.	.10½ – .11	.12 – .15½
Carbonyl chloride (phosgene)	lb.	.....	.75 – 1.00
Caustic potash (see potassium hydroxide)		.....	.....
Caustic soda (see sodium hydroxide)		.....	.....
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.08 – .....
Chloroform	lb.	.28 – .29	.30 – .31
Cobalt oxide	lb.	.....	1.50 – 1.55
Copperas (see iron sulphate)		.....	.....
Copper carbonate, green precipitate	lb.	.27 – .28	.29 – .31
Copper cyanide	lb.	.....	.65 – .70
Copper sulphate, crystals	lb.	.08½ – .09	.09 – .09½
Cream of tartar (see potassium bitartrate)		.....	.....
Epsom salt (see magnesium sulphate)		.....	3.00 – 3.25
Formaldehyde, 40 per cent	lb.	.....	.45 – .55
Glauber's salt (see sodium sulphate)		.....	.....
Glycerine	lb.	.....	.24½ – .26
Iodine, resublimed	lb.	.....	4.10 – 4.30
Iron oxide, red	lb.	.....	.03 – .20
Iron sulphate (copperas)	cwt.	1.20 –	1.25 – 1.75
Lead acetate, normal	lb.	.12 – .13	.14 – .23
Lead arsenate (paste)	lb.	.....	.13 – .17
Lead nitrate, crystals	lb.	.....	.70 – .80
Litharge	lb.	.....	.09½ – .10½
Lithium carbonate	lb.	.....	1.50 – .....
Magnesium carbonate, technical	lb.	.....	.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	2.15 – 2.63	2.75 – 3.00
Magnesium sulphate, commercial	100 lb.	1.75 –	2.00 – 2.50
Nickel salt, double	lb.	.14 –	.15 – .....
Nickel salt, single	lb.	.12½ – .13	.17 – .....
Phosgene (see carbonyl chloride)		.....	.....
Phosphorus, red	lb.	.....	.60 – .65
Phosphorus, yellow	lb.	.....	.35 – .37
Potassium bichromate	lb.	.32 – .33	.34 – .37
Potassium bitartrate (cream of Tartar)	lb.	.....	.56 – .60
Potassium bromide, granular	lb.	.....	.50 – .65
Potassium carbonate, U. S. P	lb.	.60 –	.65 – .70
Potassium carbonate, crude	lb.	.26 – .27	.28 – .30
Potassium chlorate, crystals	lb.	.16 – .20	.21 – .....
Potassium hydroxide (caustic potash)	lb.	.28 – .32	.35 – .42
Potassium iodide	lb.	.....	3.35 – 3.60
Potassium nitrate	lb.	.19 –	.21 – .....
Potassium permanganate	lb.	.....	$0.65 – $0.95

*Nominal quotations.

		Carlots	Less Carlots
Potassium prussiate, red	lb.	1.00 – 1.05	1.10 – 1 20
Potassium prussiate, yellow	lb.	.....	.40 – .70
Potassium sulphate	ton	$225.00 –	.....
Rochelle salts (see sodium potas. tartrate)		.....	.....

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.34 —	.42
Aniline oil, drums extra	lb.	.34 —	.45
Aniline salts	lb.	.42 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.05 —	1.25
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.55
Beta naphthol, sublimed	lb.	.65 —	.80
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 —	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.85 —	1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.80 —	1.00
Cresylic acid, 50%, first quality, drums	gal.	.70 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline	lb.	.95 —	1.20
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine	lb.	.55 —	.65
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3.75 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.80 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.12 —	.18
Paranitrani'ine	lb.	1.00 —	1.35
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.15 —	3.00
Paratoluidine	lb.	1.75 —	2.50
Phthalic anhydride	lb.	.60 —	.80
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 —	.25
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.43 —	.45
Salicylic acid, U. S. P.	lb.	.55 —	.60
Salol	lb.	.90 —	.95

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.22	—	$0.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.25	—	.30
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	.....
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42	—	$0.45
Beeswax, refined, yellow	lb.	.47	—	.48
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1	lb.	.80	—	.88
Carnauba, No. 2, regular	lb.	.65	—	.78
Carnauba, No. 3, North Country	lb.	.46	—	.48
Japan	lb.	.18½	—	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.....	—	.07½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	—	.07½
Paraffine waxes, refined, 118-120 m.p.	lb.	.....	—	.10¼
Paraffine waxes, refined, 128-130 m.p.	lb.	.09¼	—	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	.....	—	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	.....	—	.14
Stearic acid, single pressed	lb.	.23	—	.26
Stearic acid, double pressed	lb.	.28	—	.29
Stearic acid, triple pressed	lb.	.32	—	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist.	gal.	.....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.48
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.60
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.45	—	$18.50
Rosin E-I	280 lb.	17.50	—	18.75
Rosin K-N	280 lb.	18.50	—	21.50
Rosin W. G.-W. W.	280 lb.	20 75	—	24.25
Wood rosin, bbl.	280 lb.	16.25	—	17.50
Spirits of turpentine	gal.	.....	—	1.94
Wood turpentine, steam dist.	gal.	.....	—	1.93
Wood turpentine, dest. dist.	gal.	.....	—	1.85
Pine tar pitch, bbl.	200 lb.	8.25	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	14.75
Retort tar, bbl.	500 lb.	15.00	—	15.25
Rosin oil, first run	gal.	.93	—	.95
Rosin oil, second run	gal.	.95	—	.97
Rosin oil, third run	gal.	1.10	—	1.15
Rosin oil, fourth run	gal.	.....	—	1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.44	—	$0.46
Upriver coarse	lb.	.33	—	.35
Upriver caucho ball	lb.	.33½	—	.34½
Plantation—First latex crepe	lb.	.48	—	.49
Ribbed smoked sheets	lb.	.47	—	.48
Brown crepe, thin, clean	lb.	.42	—	.43
Amber crepe No. 1	lb.	.45	—	....

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.18	—	$0.19
Castor oil, AA, in bbls.	lb.	.21	—	.23
China wood oil, in bbls.	lb.	.24¾	—	.25¼
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18½	—	.19½
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½	—	.23
Corn oil, crude, in bbls.	lb.	.19	—	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.19	—	.20
Cottonseed oil, summer yellow	lb.	.22	—	.27
Cottonseed oil, winter yellow	lb.	.24½	—	.25½
Linseed oil, raw, car lots	gal.	1.77	—	1.87
Linseed oil, raw, tank cars	gal.	1.70	—	1.80
Linseed oil, boiled, car lots	gal.	1.75	—	1.80
Olive oil, commercial	gal.	3.00	—	3.10
Palm, Lagos	lb.	.16½	—	.16½
Palm, bright red	lb.	.16½	—	.17½
Palm, Niger	lb.	.16	—	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23½	—	.24
Peanut oil, refined, in bbls.	lb.	.27	—	.28
Rapeseed oil, refined in bbls.	gal.	1.45	—	1.68
Rapeseed oil, blown, in bbls.	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19	—	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.17½	—	.20

FISH

Winter pressed Menhaden	gal.	$1.20	—	....
Yellow bleached Menhaden	gal.	1.23	—	....
White bleached Menhaden	gal.	1.25	—	....
Blown Menhaden	gal.	1.26	—	....

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ½-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

LOS ANGELES—The Los Angeles Soap Co., 633 East 1st St., has awarded the contract for the construction of a 1-story, 45x125-ft. factory at 1st and Banning Sts., to the Davidson Constr. Co., 1445 East 16th St., at $23,800.

Idaho

MALAD—The Town Council will soon award the contract for furnishing labor and material for the construction of 2,800 ft. 18-in. vitrified tile and 2,300 ft. open canal sewer in Dist. 1. A 30x50-ft. septic tank will be included in the project. J. H. Giles, engr.

Illinois

CHICAGO—The Acme Steel Goods Co., 2834 Archer Ave., has awarded the contract for the construction of a 1-story, 150x600-ft. building to house twenty 10-in. cold roll mills and corresponding ovens, etc., adjoining its present plant at Riverdale, to R. F. Wilson & Co., 1851 Elston Ave.

CHICAGO—The Concrete Steel Co., 53 West Jackson St., has awarded the contract for the construction of a 1-story, 80x100-ft. factory at Central Park Ave. and 31st St., to James Shedden & Co., 106 North La Salle St. Estimated cost, $25,000.

MOLINE—Williams, White & Co., 3rd Ave. and 8th St., plans to build a 1-story, 110x325-ft. foundry on 43rd St., between 3rd and 4th Aves. C. A. Hardy Co., Ry. Exch. Bldg., Chicago, engr.

Indiana

HAMMOND—The La Salle Steel Co., 2243 South Halsted St., has purchased a site on the North Side and plans to build a steel fabricating plant, consisting of 3 buildings, on same. Estimated cost, $1,000,000.

INDIANAPOLIS—The Acme Aluminum & Brass Wks., 420 South Harding St., is having plans prepared for the construction of factory. Estimated cost, $70,000.

INDIANAPOLIS — The Van Briggle Chemical Co., 16th St. and Capital Ave., will receive bids about March 1 for the construction of a chemical manufacturing plant. Estimated cost, $125,000. Charles E. Bacon, 1110 Odd Fellows' Bldg., archt.

Iowa

STANTON—The city will receive bids until March 4 for the construction of sewers and a disposal plant. Estimated cost, $60,000. Theodore S. DeLay, Creston, engr.

Louisiana

NEW ORLEANS—The Go-Ro Co., 826 Barrone St., plans to build a factory and is in the market for a Joet Ram squeeze molding machine, milling machines, screw milling and Fox monitor, cupola, tumbling mills, sand blast machine, core oven, etc. Estimated cost, $150,000.

Michigan

GRAND RAPIDS—The Toledo Plate & Window Glass Co., 19 Ottawa Ave., has awarded the contract for the construction of a 2-story, 123x130-ft. factory, including warehouse and office building, to C. Hoertz & Sons, 659 Bridge St. Estimated cost, $95,000.

NORTHVILLE—C. Freiburger, secy., Bd. of Health, 233 St. Antoine St., Detroit, will receive bids until March 1 for the construction of a 2-story, 28x36-ft. laboratory, in connection with the group of buildings to be constructed at the proposed Detroit Municipal Tuberculosis Sanitarium. Laboratory equipment will be installed in same. Stratton & Snyder, 1103 Union Trust Bldg., Detroit, archts.

Missouri

KANSAS CITY—The Cleveland Steel Barrel Co., 9612 Meech Ave., Cleveland, plans to build an 80x290-ft. factory at Southwest Blvd. and Hill St. This will be the first unit of a Western plant.

New Jersey

TRENTON—The Joseph Stokes Rubber Co., Taylor St., has awarded the contract for the construction of a 2-story, 70x100-ft. rubber factory, to N. A. K. Bugbee Co., 206 East Hanover St. Estimated cost, $35,000.

TRENTON—The Mercer Motor Co., Whitehead Rd., has awarded the contract for the construction of a 2-story, 40x73-ft. office building and a 1-story, 80x400-ft. paint shop, to the Standard Constr. Co., 1713 Sansom St., Philadelphia. Estimated cost, $200,000. Noted Jan. 28.

New York

BATAVIA—The city has revised plans prepared by A. Clark, city engr., for the installation of a gravity sewage disposal system to replace present pumping system. Estimated cost, $200,000.

ELMIRA—The General Electric Co., Hulett Bldg., has awarded the contract for the construction of a 1-story, 110x560-ft. foundry, to H. K. Ferguson Co., 6532 Euclid Ave., Cleveland. Estimated cost, $300,000.

NIAGARA FALLS—The Kimberly & Clark Co., Neenah, Wis., will receive bids for the construction of a paper mill on Royal Ave. Estimated cost between $175,000 and $200,000.

ROCHESTER—The New York Sewer Pipe Co., 545 Oak St., plans to rebuild the 5-story building which was recently destroyed by fire, entailing a loss from $40,000 to $50,000.

ROCHESTER—Sargent & Greenleaf Co., Court St., manufacturer of locks, plans to construct a 1-story, 185x214-ft. factory, 2-story, 40x214-ft. office building and a 1-story, 40x128-ft. brass foundry and power house on Norton St. The company is in the market for foundry equipment.

SYRACUSE—The Oberdorfer Brass Co., Water St., plans to build a 1-story, 280x440-ft. auto castings factory at Messina Springs. Estimated cost, $350,000. M. L. King, Snow Bldg., engr.

TUCKAHOE—The Hodsman Rubber Co. will soon award the contract for the construction of a 5-story, 60x150-ft. factory addition. Estimated cost, $200,000. W. L. Stoddart, 9 East 40th St., New York City, archt. and engr.

North Dakota

COOPERSTOWN—The city plans to construct a complete sewerage system, including a disposal plant, etc. Cost to exceed $25,000. Dakota Eng. & Constr. Co., Valley City, engr.

MAYVILLE—The city voted $10,000 bonds for the installation of a water-softening plant. T. R. Atkinson, Bismarck, engr.

Ohio

CLEVELAND—The Amer. Stove Co., 4700 Perkins Ave., has awarded the contract for the construction of a 2-story, 233x265-ft. enameling plant at 4100 Hough Ave., to the Boldt Constr. Co., 6110 Euclid Ave. Estimated cost, $150,000.

CLEVELAND—The Buckeye Brass Co., 6410 Hawthorne Ave., will receive bids until March 1 for the construction of a 1-story, 30x110-ft. foundry and a 75x75-ft. furnace room on Ashland Rd. Estimated cost, $60,000. N. W. Carl, secy. Allen Sogg, 319 Hippodrome Bldg., archt.

CLEVELAND—The Ohio Fibre Container Co., 209 Williamson Bldg., plans to build 2-story factory additions at East 103rd St. and Harvard Ave. Estimated cost, $75,000. D. Jones, secy.

CLEVELAND—The Otis Steel Co., Leader-News Bldg., has awarded the contract for the construction of five steel mill buildings, to be 2-story, 75x400-ft., 1-story, 90x400-ft., 1-story, 40x400-ft., and 1-story, 80x400-ft., on Jennings Rd. to the Amer. Bridge Co., 30 Church St., New York City. Estimated cost, $500,000.

CLEVELAND—The Perfection Rubber Co., 2097 Columbus Rd., is having plans prepared for the construction of a 2-story, 100x110-ft. factory building on Brook Park Rd. Estimated cost, $60,000. L. J. Johnson, vice pres.

CLEVELAND—The United States Gypsum Co., 1714 Merwin Ave., plans to rebuild the 2-story factory which was recently destroyed by fire. Estimated cost, $100,000. P. A. Ryder, supt.

GRAFTON—The village will receive bids about April 15 for the construction of a sewerage system and a sewage disposal plant, including two sedimentation tanks. Estimated cost, $30,000. R. Winthrop Pratt, Hippodrome Bldg., Cleveland, engr.

Oklahoma

OKEMAH—The town is having plans prepared for the construction of an entire new plant, including a disposal plant. Estimated cost, $90,000. V. V. Long & Co., 1300 Colcord Bldg., Oklahoma City, engr.

Pennsylvania

LOCK HAVEN—The Castanea Paper Co. has awarded the contract for the construction of a paper mill, including a 2-story, 425x515-ft. mill, 1-story, 60x150-ft. storehouse, and a series of clay bins, to the Turner Constr. Co., 244 Madison Ave., New York City. Estimated cost, $1,250,000.

PLAINS—The city plans to construct a sewerage system, including a sewage disposal plant. Estimated cost, $400,000.

WILKES-BARRE—The Sheldon Axle Co., 221 Conyngham Ave., plans to build a 3-story, 100x200-ft. heat treating plant on Beaumont St. Estimated cost, $200,000.

Texas

BROWNWOOD—The city plans to construct a sewerage system and a sewage disposal plant, on the South Side of the city. This plant will be another unit to the present system. Estimated cost, $50,000. E. R. Brashear, city mgr.

HOUSTON—The Lone Star Steel & Bridge Co., 214 Carter Bldg., will soon have plans prepared for the construction of a fabricating plant, having a 1,000-ton capacity per month, on Harrisburg Blvd. and the Municipal R.R. tracks. G. E. Cole, pres.

Washington

VANCOUVER — The Columbia Dairy Products Co. plans to build a 2-story, 40x80-ft. dairy plant. Pasteurizing and condensing equipment will be installed in same. Estimated cost, $45,000.

West Virginia

ELKINS—The city plans to construct a pumping station and filtration plant. Estimated cost, $130,000.

Wisconsin

KILBOURN—A. Luettgerodt, city clk., will receive bids until March 10 for the construction of a sewerage system, including a 12x15-ft. septic tank. Estimated cost, $18,000 to $20,000. Parsons & Orbert, 627 M. & M. Book Bldg., Milwaukee, engrs.

MANITOWOC—The Wisconsin Aluminum Products Co., c/o B. Dalwig, mgr., 16th and Franklin Sts., plans to build a 4-story, 60x250-ft. aluminum products factory on 8th St. Estimated cost $250,000.

MILWAUKEE—The Milwaukee Rolling Mill Co. has awarded the contract for the construction of a 1-story, 380x425-ft. steel rolling mill, to the Northwestern Bridge & Iron Co., 32nd and Hopkins Sts. Annealing ovens and oven equipment will be installed in same. Estimated cost, $400,000.

MILWAUKEE—The Pelton Steel Co., 672 Kinnickinnic Ave., has awarded the contract for the construction of a 1-story, 60x100-ft. foundry addition, to Yunker Bros., 615 37th Ave. Estimated cost, $50,000. Noted Feb. 4.

SHEBOYGAN—The Armour Leather Co., 175 North Franklin St., Chicago, has awarded the contract for the construction of a tannery, here, to Westinghouse, Church, Kerr & Co., Inc., 37 Wall St., New York City. Estimated cost, $750,000.

SOUTH WILWAUKEE (Milwaukee P. O.)—C. P. Nourse, c/o Stowell Co., is in the market for plating machinery and japaning ovens.

Ontario

BRANTFORD—The Blue Bird Co. is in the market for acetylene welding equipment, etc.

GALT—The Galt Brass Co. will construct a 58x138-ft. foundry and a 40x90-ft. extension to its vitriol plant.

KITCHENER—The Kitchener-Waterloo Collegiate Bd. is having plans prepared for the construction of a 3-story collegiate institute. Chemical and physical laboratory supplies will be installed in same. Estimated cost, $500,000. S. B. Coon & Son, 810 Excelsior Life Bldg., Toronto, archts.

OTTAWA—The Bd. of Control will receive bids in the spring for the construction of laboratories and a press building on the exhibition grounds. Estimated cost, $50,000. A. F. Macallum, City Hall, engr.

OTTAWA—The Council of the County of Carleton will receive bids in the spring for furnishing one oil distributor with heater, etc., for the Highway Dept. Patterson & Byrne, 7½ Sparks St., engrs.

Quebec

BAY DE CHALEUR—Arthur Sande, consult. engr., Lister Bldg., Hamilton, Ont., will soon award the contract for the construction of a 200-ton sulphite pulp mill, here.

LACHINE—A. Laframboise, engr., City Hall, is preparing plans for the construction of a filtration plant, etc., for the city. Estimated cost, $300,000.

THREE RIVERS—The Wayagamack Pulp & Paper Co. is building a pulp mill, here. Estimated cost, $3,000,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will hold a meeting on March 26, the subject of which is "Peace Uses for War Products."

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE CANADIAN MINING INSTITUTE will hold its annual meeting at the King Edward Hotel, Toronto, March 8 to 10.

THE FARADAY SOCIETY (London) will hold a joint meeting, March 1, with the London Section of the Society of Chemical Industry to receive and discuss a report of Dr. T. Martin Lowry, and E. C. Hemmings on the "Setting of Salts and Other Crystalline Substances." Another meeting will be held March 23, at which there will be a general discussion on "Basic Slag From the Metallurgical and Agricultural Standpoints."

THE INSTITUTE OF METALS will hold its annual general meeting March 11 and 12 at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S. W. 1, London, England.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MATERIAL HANDLING MACHINERY MANUFACTORERS' ASSOCIATION will hold its convention at the Waldorf-Astoria Hotel, New York City, Feb. 26 and 27.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Industrial Notes

THE TRUSCON STEEL CO. has opened a branch sales office in El Paso, Tex., and is carrying a stock of $100,000 in plates and girder connection. W. A. E. Wood is the local manager.

THE UNITED STATES RUBBER CO. has acquired the plant and business of the Dolgeville Felt Shoe Co., Dolgeville, N. Y. The present management will be continued.

THE MINE & SMELTER SUPPLY CO., Denver, Col., announces that W. A. Leddell has been appointed manager of its engineering department, with headquarters in Denver. Problems relating to Marcy mills, Wilfley tables and other Massco specialties and the preparation of flow sheets and specifications will come under the supervision of Mr. Leddell's department.

THE HAUCK MFG. CO., Brooklyn, N. Y., manufacturer of oil burners, has recently made some changes in the location of its burner service stations, for the purpose of improving its facilities for service and demonstration. The Pittsburgh station has been moved from 2930 Penn Ave. to 105 Wood Street; the Boston station from 70 Hight St. to 149 Berkeley St., cor. Columbus Ave.; the Cleveland station from 2114 Superior Viaduct to 1106 Walnut Ave.

JOHN JOHNSON CO., Brooklyn, N. Y., manufacturer of filter presses, announces that it has acquired the services of Colonel M. E. Brewster-Green, who has recently returned from two years' staff duty in France and Italy. Colonel Green was formerly assistant advertising manager for the Locomobile Co. of America.

THE ELECTROLABS CO., New York, announces the consolidation of all offices at 2635 Penn Ave., Pittsburgh, Pa. A branch office is maintained at 30 Church St., New York City.

HUMMEL & ROBINSON, New York, advises that arrangements have been made with W. R. Sturges to act as its representative and agent for the Southern territory for the sale of dry colors and chemicals. Mr. Sturges was formerly with Reichard-Coulston, Inc., New York.

BUTTERWORTH-JUDSON CORP., New York, announces the following appointments: Fred E. Signer, general sales manager, vice W. H. Clark, resigned; E. A. MacKinnon, assistant sales manager; J. D. Lowery, assistant sales manager, and George E. Green, traffic manager.

THE BOOTH ELECTRIC FURNACE CO. has opened a Detroit office in charge of M. A. Beltaire, Jr., with headquarters at 805 Hammond Bldg. and an office in Birmingham, Ala., in charge of Gassman & Cunningham, in the Brown & Marx Bldg.

THE PHOENIX IRON WORKS CO., Meadville, Pa., announces the appointment of K. B. Thorndike as sales engineer, in charge of its New York office, Fifth Ave. Bldg.; also the opening of a Boston office in the Old South Bldg., with Paul C. Rodgers, district sales manager, in charge. These changes are in line with the policy of this company, in order to make its branch offices of service to its customers not only as sales offices but also from an engineering standpoint.

THE CHICAGO PNEUMATIC TOOL CO. on Jan. 21 and 22 held a general conference of executives, plant and branch managers and salesmen at its Detroit plant, on the occasion of the formal opening of a large five-story addition.

THE MANSFIELD CLAY PRODUCTS CO., Mansfield, Ohio, has changed its name to the Mansfield Shale Products Co., the change being deemed advisable inasmuch as the operations of the company are confined chiefly to shale.

THE AMERICAN METALLURGICAL CORP., Philadelphia, Pa., at the annual stockholders' and directors' meeting elected the following officers and directors for the coming year: F. J. Ryan, president; S. R. Vanderbeck, vice-president; W. L. Taylor, treasurer; J. L. Hawley, assistant treasurer, and S. H. Ourbacker, secretary.

THE BURRELL TECHNICAL SUPPLY CO., INC., Pittsburgh, Pa., has been organized to conduct a general laboratory and technical supply business. A catalog devoted entirely to apparatus for gas analysis will soon be off the press. The officers of the company are Colonel G. A. Burrell, president; J. T. Ryan, vice-president; G. H. Deike, treasurer, and G. C. Nelms, secretary.

"THE NURSE IN INDUSTRY" is the title of a pamphlet published by the National Organization for Public Health Nursing, 156 5th Ave., New York City. Copies will be sent on request to those who are interested in the work of industrial nurses.

THE STEEL BARREL MANUFACTURERS ASSOCIATION held its annual meeting in Chicago in December. The activities of the Association during 1919 included efforts to standardize the different types of steel barrels and drums as well as size of threads and character of flanges and plugs. The committee having this in charge cooperated with the Bureau of Explosives and recommendations have been made for strengthening the I. C. C. specifications. The committee on minimum weights and various styles of packages did considerable work to protect the buyer from unscrupulous manufacturers. Other committees reported on publicity, legislation, railroad rates, and cost-accounting systems. The officers elected for the ensuing year were: G. A. Moore of the Detroit Range Boiler & Steel Barrel Co., president; Mr. Kinney of the Metal Barrel Corp., vice-president, and D. S. Hunter, secretary-treasurer.

THE JOSEPH BROWN CO., of Woonsocket, R. I., has been organized to manufacture chemicals, etc. The capital stock of the company is $100,000, and the incorporators are as follows: Joseph Brown, Arthur H. Heen and Arthur B. Martel, all of Woonsocket, R. I. All are experienced in the line of chemical goods, and business will be engaged in shortly. All communications should be addressed to Joseph Brown, care of Joseph Brown Co., Woonsocket, R. I.

WAR INDUSTRIES BOARD Bull. 34. "Prices of Ferro-Alloys, Non-ferrous and Rare Metals," by H. R. Aldrich and Jacob Schmuckler.

GLUE USED IN AIRPLANE PARTS, Report No. 66, issued by the National Advisory Committee for Aëronautics, Washington, D. C.

THE ELECTRIC FURNACE is the title of a 16-page magazine published by the Electric Furnace Co., Alliance, Ohio. Vol. 1, No. 1, is dated January, 1920, and is to be succeeded by monthly issues.

THE NATIONAL RESEARCH COUNCIL of the National Academy of Sciences, Washington, D. C., has started the *Bulletin* of the National Research Council, which is to appear at irregular intervals. Vol. 1, Part 1, No. 1, dated October, 1919, has appeared. In this issue the national importance of scientific and industrial research is discussed by George E. Hale, Elihu Root, Henry S. Pritchett, Theodore N. Vail, Ambrose Swasey, A. W. Mellon, George Eastman, Walter Douglas, James R. MacColl and H. W. Howe.

THE REPORT ON PROPAGATION OF FLAME IN PIPES AND EFFECTIVENESS OF ARRESTORS, which is Special Investigation Series No. 528, dated Oct. 1, 1919, has been issued by the Underwriters Laboratories, Chicago, Ill.

METALLURGICAL PATENTS OWNED BY THE CHEMICAL FOUNDATION, INC., 81 Fulton St., New York City. This pamphlet contains abstracts of patents seized by the Alien Property Custodian and sold to the Chemical Foundation. Copies of the patents are available for examination at the office of the Chemical Foundation, Inc.

VAT DYE PATENTS OWNED BY THE CHEMICAL FOUNDATION, INC., 81 Fulton St., New York City. This pamphlet contains abstracts of patents seized by the Alien Property Custodian and sold to the Chemical Foundation. Copies of the patents are available for examination at the office of the Chemical Foundation, Inc.

Manufacturers' Catalogs

THE OXYGEN GAS CO., Kansas City, Mo., has issued pamphlets on "Oxygen and Hydrogen Gases," with particular reference to the use of hydrogen for oil hardening, and on the "Advantages of Nitrous Oxid-Oxygen as an Anesthetic."

THE BLAW-KNOX CO., Pittsburgh, Pa., has recently issued a new Blawforms folder, illustrating the application of Blaw steel forms for concrete construction.

VIELE, BLACKWELL & BUCK, New York City, have issued a series of bulletins which should prove of value to companies engaged in foreign trade. The organization maintains an engineering section to design, purchase and conduct all classes of industrial plants and a foreign trade section which handles both for export and import a great variety of raw, semi-finished and finished products, which are listed in Bulletin A. In other bulletins the company has compiled a vast amount of information on ferrous and non-ferrous metal products and heavy chemicals.

Colonel Fries Heads Chemical Warfare Service

ANNOUNCEMENT is made from Washington that Major-General WILLIAM L. SIBERT, who has been Director of the Chemical Warfare Service, has been relieved of his duties and ordered to Camp Gordon, Ga., to command the Fifth Division. Lieutenant-Colonel AMOS A. FRIES, who was in charge of Chemical Warfare Service overseas during the war, succeeds General SIBERT as Director. Both General SIBERT and Colonel FRIES have been active in support of the proposal to make the Chemical Warfare Service a separate branch of the Army instead of merging it with the Corps of Engineering. Their views have evidently prevailed, because the Army Reorganization Bill now before Congress recognizes the Chemical Warfare Service as a separate entity.

We regret the removal of General SIBERT from the Service, but welcome the appointment of Colonel FRIES as his successor. It is essential at this time to have an intelligent, sympathetic, enthusiastic officer at the head of the Service and Colonel FRIES embodies these qualities in quite as high a degree as did General SIBERT.

If our own wishes had been consulted, there would have been no change, but if it is impossible to have both of these officers in the organization, we are glad that one of them is still available.

Government Appropriation For the Forest Products Laboratory

AN APPROPRIATION has been requested from Congress by representatives of the wood-using industries for the support of the Forest Products Laboratory during the coming year. The Secretary of Agriculture has cut the original amount of $500,000 to $350,000, and the House Committee on Agriculture now further trims this sum.

The institution needs $500,000. The many industrial concerns dependent on its researches demand it. Yet we find Congress, under the guise of saving money, planning to handicap one of the most serviceable of Government establishments. The honorable gentlemen are surely acting without a real knowledge of the functions and scope of activity of the Laboratory. CHEMICAL & METALLURGICAL ENGINEERING outlined the features of this work in the December 24, 1919, issue, and additional data are available in the Government files. The future development of the art is largely dependent on research work at Madison. The legislator who runs must read. There is often a mistaken idea of "the broader view." Economy becomes an obsession and the most worthy cause is ruined through the money-saving mania.

Chemistry, Metallurgy and The Bureau of Standards

APPROPRIATIONS requested for chemical investigations and service to allied industries by the United States Bureau of Standards, meager as they have been in the past, will be still further curtailed if the appropriation bill as submitted to the House of Representatives passes without amendment in the form of increases. Investigation discloses the fact that all appropriations for supplying standard samples of iron and steel, ores, materials for calorimetry and acidimetry have been cut off, and that the appropriation for determining the physical constants of materials is also eliminated. Furthermore, several of the best-paid chemical positions in the Bureau are about to be abolished.

The appropriation for the Bureau of Standards for the fiscal year ending June 30, 1920, is $1,853,260. The requested appropriation for the fiscal year ending June 30, 1921, is $2,986,440. The appropriation carried by the bill now in the House for the next fiscal year is $1,217,360. We are hardly in accord with the idea of increasing at this time the annual appropriation for the Bureau by over one million dollars, but we are certain that last year's appropriation should not be scaled by over 30 per cent as proposed in the House bill.

Is Congress aware of the fact that preparation of standard samples was a money-making activity for the Bureau last year? In the recent report of the Director we note that the actual cash receipts from this work totaled more than $6,000, while only $5,000 was appropriated therefor. Even if this activity had not shown a cash profit, its service to the chemical and metallurgical industries is such that it should not be abandoned.

It is evident that if the industries want technical investigations by the Bureau to continue next year it will be necessary to lay the facts before the House Committee on Ways and Means. In all probability it will be found that the committee merely lacks the necessary information to enable it to appreciate the work which the Bureau is doing. Unless something is done to support this project, the work will be interrupted and the industries will be compelled to try to do for themselves individually those things which are natural functions of our national Bureau of Standards.

During the war no Federal bureau made more fundamental and important contributions to the national welfare than did the Bureau of Standards. Any organization which functioned as vitally as this Bureau at that time should not be handicapped in its normal development and operation, nor crippled in its peace-time industrial service.

Who Knows About Shale Oil?

OIL-SHALE promotion has passed the crest of the first wave. Two years ago, under the enthusiasm of a war-time need of rivers of gasoline to propel subchaser, tank, tractor, truck and airplane, many men convinced themselves and others that the failing supply from available crude could be quickly augmented from the stupendous reserves locked up in oil shale. So patriotic promoters immediately began their double campaign for oil production and thrifty investment with a vim, and made a deal of noise and collected not a few stray dollars, but, needless to say, produced no "gas" of a variety usable in internal combustion engines.

Since most of the stray pigeons were then plucked, it is now more popular to produce evidence of substantial effort toward the recovery of oil when selling stock certificates. Consequently not a few men have swelled the numbers of those already considering seriously ways and means to get oils, gases and fertilizers from shale. While a year ago it might fairly be said that the total production of oil from shale could be loaded on one truck, during the interval some experimental work on a semi-commercial scale has taken place in a few localities with a corresponding gain in knowledge, at least as to what kind of a plant should not be built.

Without desiring to add to the endless discussion as to whether the Scottish shale retorts should be adapted to American problems, whether byproduct coke ovens would be the proper point of departure, or whether some entirely new kind of muffle, roaster or calciner should be designed, it appears not unreasonable to believe that if a resourceful organization with proper financial backing should take more than a passing interest in the problem, a retort quite well suited to recover oil and gas from the particular shale to be treated could be soon devised. This is only a restatement of the opinion already voiced more than once in these columns that the successful utilization of shale will require a generous supply of competent technical and administrative talent.

At the present time, progress toward a solution of the problem is disappointingly slow, probably due to the fact that the resourceful organization has not yet become interested.

We have become accustomed to expect fruitful investigations of little-known natural resources from the Bureau of Mines, but this organization has badly diffused itself. The work begun at Salt Lake City has been halted; the Southern Pacific's retort plant at Elko, Nev., built under supervision of the Bureau's consultant, DAVID T. DAY, has not yet been fired up; a hopeful co-operative plant to be located in western Colorado has not yet materialized; and useful results from the work just initiated at Boulder, Col., cannot be expected for some time.

In the meantime, there is one big factor in the problem which has not been given the attention it deserves. It has been shown already that the oil produced on a small scale from various American shales has quite different characteristics from any of the crude petroleums now on the market. In fact, it is so different that grave doubts are entertained as to whether it can be sold in quantity to existing refineries. Such being the case, any organization intending large-scale production would be well advised to begin by purchasing a considerable quantity of shale oil from one of the plants now operating, and institute a vigorous research at some well-equipped laboratory—such as the Mellon Institute —to determine its composition, its proper treatment, and commercial outlets for various easily procured fractions.

After all is said, the composition of the oil from a given shale bed is not going to be vitally changed by the small changes which are likely to develop in the retorting process—differing proportions in the fractions will be the greatest effect noticed. The Bureau of Mines' work may eventually be expected to give such data as the specific heat of the shale, its conductivity, and the effect of fine grinding, rate of heating and such factors on the yield of oil. These figures will all be available for use in the technical design of retorts, but the oil will still be a big problem after the retorting has been standardized.

It therefore seems to be a wise procedure to study the oil intensively, so that a plant with a sizable output of shale oil may not find itself with a white elephant on its hands.

Professor Haber And the Nobel Prize

THERE has been considerable criticism of the award of the Nobel prize in chemistry to Professor HABER, on account of his activities in chemical warfare in the German army. Before expressing a definite opinion we should like more facts than are available at this writing.

Inquiry from an American physical chemist of the first rank has brought the following reply:

> So far as HABER'S scientific deserts are concerned, his fellow-countryman NERNST is the only physical chemist in the world who hasn't the prize already who deserves it as much as HABER.

We may say right here that if NERNST had received it we should have been ready to express an opinion without hesitation. He belongs to the class of brilliant, able, original men who aided in giving to the German people their present burden of reputation. Another of the same type in the technical world is Professor DUISBERG, who visited America in 1912 and gave an illuminating performance of German offensiveness. Our correspondent continues:

> NERNST was made a Count for his contributions to gas warfare, but their relative merits for the prize do not affect the issue. HABER is a brilliant, forceful, successful investigator who has worked in many branches of physical chemistry and has illuminated every one of them. I cannot recall another text book that has borne such rich fruit as his work on Thermodynamics of Technical Gas Reactions. His special work on the ammonia synthesis is but a single, isolated application of this broader study. He is a pioneer and leader in our science.
>
> Personally I cannot say much at first hand about him. but what little I saw I liked . . . American and English students sought him out in large numbers, and they all liked him very much. Indeed I know of no other German chemist of the period, unless it was LUTHER or ABEGG, whom the Americans seemed to like so well.
>
> So far as his activities in the war are concerned, I know nothing at first hand and have heard nothing authoritative about him. Some say he, others say NERNST, was the originator of gas warfare. It does not seem very likely that HABER began it, for he finished as a Captain. Most people who get in on the ground floor manage to do better.
>
> If with the gas problem already decided upon by the General Staff and under way, the government ordered him to assist and direct such work, he isn't in a very different boat from many of us here. If he did originate

and advocate gas warfare, realizing its terrible potentialities, he deserves the contempt and execration of humanity. And he will get it.

It is hard enough to render judgment on a man even when you know that you know the facts; it is criminal to condemn him when you know that you don't know the facts. One precious heritage of our Anglo-Saxon past is the recognition that a man is innocent until he is proved guilty. Why throw this over when mercy—the safety of the weak—and justice are the very things we have been fighting to preserve?

This seems a fair presentation.

All Germans are not alike, although in war they seem so. A couple of years ago they were united in the most outrageous attack ever known upon the welfare of humanity, and we earnestly hope that they have been sufficiently beaten to know that they must never do so any more.

As individuals, however, they continue to live, and if any of their number deserves credit we should not withhold it from him.

Mr. Sulman's Contribution To the Study of Flotation

IT SHOULD be the unvarying custom of the scientist and the engineer carefully to scrutinize all technical or scientific matters coming before them, and apply to them the analytical methods of scientific research. It behooves the editor of a scientific and technical magazine also consistently to maintain this attitude of mind and practice in his own particular province, and to apply critical scrutiny to the technical papers which come to his notice.

Some months ago H. L. SULMAN presented a long paper before the Institution of Mining and Metallurgy, London, on "A Contribution to the Study of Flotation." The great length of the paper probably has prevented its widespread republication, despite the superficial evidence of its importance. The appearance in print on so elaborate a scale of an article on flotation by Mr. SULMAN after years of silence on his part and evident censorship by his employer, Minerals Separation, Ltd., has been a cause for comment. Elsewhere in this issue we publish an analysis of some of the facts relating to this belated contribution of Mr. SULMAN. One cannot help asking whether the paper now published contains the essential data which its author presumably had prepared for publication many years ago. His statements and those of his critics who discussed the article leave one in a confused state of mind as to the sincerity and reliability of the contribution.

In view of the disclosures by the U. S. Federal Trade Commission of the close commercial relations maintained during the war by Minerals Separation, Ltd., with Beer, Sondheimer & Co., we cannot help suggesting to our brother engineers in London that they should use all proper caution to see that their Institution is not prostituted to the service of corporate greed in the form of the late enemies of the British Empire and of all mankind.

In the interest of science and justice we believe that they should also use their influence to see that the original scientific treatise prepared jointly by Messrs. SULMAN and PICARD shall be published as originally written without the crossing of a "t" or the dotting of an "i."

The scientific world is entitled to this paper, the cause of justice demands its production, and Mr. PICARD is entitled to its publication in a form to which he is willing to subscribe his name as co-author with Mr. SULMAN.

If purely scientific rather than business considerations have changed its authors' conceptions since this work was first written, proper footnotes could convince the public of their scientific disinterestedness.

The Wilson Dam At Muscle Shoals

AN ESSENTIAL part of the project to establish nitrogen fixation plants at Muscle Shoals was the construction of a dam and hydro-electric power plant at that point on the Tennessee River. Work on the project was authorized during the war, but it was soon found necessary to discontinue it for several reasons. In the first place, it was doubtful if the work could be completed before the war ended, and in the second place, it was a project of such magnitude as to require labor and materials which could not be diverted from other war needs. Now, however, the work is again under way, under the direction of the Engineers Corps of the Army, and a progress report is printed elsewhere in this issue.

With the controversies which have centered in this particular project we have no present concern. It is an undertaking which looks far into the future for its justification and we have little doubt as to the favorable judgment which will ultimately be pronounced. Certain it is that the project is located in a section of our country which has urgent need for the development of its industrial, agricultural and mineral resources, and in the long run we believe that the whole nation will profit. Political and sectional opposition and criticism against it may be expected from certain quarters, but in all probability it will be found of the same quality and inspiration which opposed the location of the nitrate plants at Muscle Shoals, but which promptly subsided when additional nitrate plants were "more favorably" located. The nitrate plants are at Muscle Shoals. They should be operated. The dam and power plant are essential to their operation, and the work should be completed at the earliest possible date.

Commercial Ambassadors In Mexico City

THE commercial conference called by the American Chamber of Commerce of Mexico in Mexico City last month was attended by representatives from many local civic bodies in the United States. President CARRANZA and other Mexican officials gave them a warm welcome.

Desire for trade begets peace in all civilizations. Mexico needs chemicals, pharmaceuticals, porcelain goods, paints, machinery of all kinds, textiles, bacteriological apparatus and other products necessary to constructive activities. In turn the United States desires in trade the tanning pod, fish oil, candelilla resin, vegetable wax, logwood, medical herbs, castor oil plant, lechuguilla fiber, vanilla beans, petroleum, etc. Mexico is a storehouse of wonderful raw materials for which the world should be her market.

This is something, then, larger than a deal in old jackknives. The meeting was a definite step toward peaceful relations and Mexican development, a consummation much to be desired.

Western Chemical and Metallurgical Field

Manufacture of High-Grade Superphosphate at Anaconda

THE proximity of a potential source of relatively cheap sulphuric acid and large deposits of high-grade phosphate rock occurs in the Rocky Mountain northwest. Sulphide ores of copper, lead and zinc are treated in the metallurgical plants in this district in large quantities. These ores, or the concentrates obtained therefrom, are in most cases roasted as a preliminary metallurgical operation. Recent developments in the production of sulphuric acid from these roaster gases indicate the possibility of the manufacture of this acid in large quantities at a low cost. At present only sufficient acid is made to take care of local consumption, since the acid will not stand transportation charges for any great distances. The unused sulphur dioxide is expelled to the air. This is not desirable, as there are certain requirements that have to be met wherever smelters are located in agricultural communities and the smoke problem is one that smeltermen would like to solve economically if possible. The removal of sulphur dioxide from these gases would avoid certain objections to the discharge of these gases into the air. Large deposits of phosphate rock occur in Idaho, Utah and Wyoming from which the rock can be mined and transported to the smelters at a reasonable cost. The production of superphosphate from these materials is a simple matter and would create an outlet for sulphuric acid, but the ordinary grade superphosphate will not stand the freight rates to the market, which is largely in the Eastern states.

Problem of Marketing Difficult

The Anaconda Copper Mining Co. has given this subject a great deal of attention and has worked out a process for the production of a superphosphate that contains 48 to 50 per cent available P_2O_5, or practically treble the percentage in the superphosphate that is ordinarily produced. This high-grade product will stand relatively high transportation costs, but the possibility of large-scale production depends upon the development of a market for this product. The marketing of this grade of superphosphate is not a simple proposition; in the first place, this material is too concentrated to be applied to the soil without mixing with inert material, and in the second place, the manufacturers of mixed fertilizers depend largely upon the inert material in ordinary phosphate to dilute high-grade nitrogen and potassium salts. The use of higher-grade fertilizers results in economy both in handling and in transportation and is desirable for both the consumer and producer. However, the education of the farmer along these lines has not as yet attained marked success. The use of larger amounts of phosphates is desirable especially in connection with the production of cereal crops; it is a characteristic of this element of plant food to bring these crops to maturity earlier and to increase the yield. Increased productivity of our agricultural lands is of national importance in view of the shortage of farm labor and the high wages demanded by experienced farm hands.

The Anaconda method of manufacturing superphosphate is to treat phosphate rock with sulphuric acid, producing a phosphoric acid, which is concentrated and used in treating additional phosphate rock. The rock is crushed in a Blake crusher, dried on a Ruggles-Cole drier and ground to pass an 80-mesh screen in a Hardinge mill, which is in closed circuit with a Newago screen. This product is treated with 60 deg. Bé. acid in a series of three Dorr agitators and the pulp washed by decantation in a series of three Dorr thickeners. The pulp is filtered and washed on an Oliver filter. The filtrate is added to the last Dorr thickener; the overflow from the second Dorr thickener is added to the first Dorr agitator. The Oliver cake is wasted. The overflow from the first Dorr thickener will contain between 22 and 25 per cent phosphoric acid. This is concentrated in a coal-fired, direct heat evaporator to about 65 per cent H_3PO_4. This concentrated acid is then mixed with ground phosphate rock in Pratt mixers, passed through a disintegrator, a Ruggles-Cole drier, ground in a Sturtevant "Ring-Roll" mill and discharged into a "den." This method of producing the superphosphate from ground phosphate rock and phosphoric acid is similar to the usual method using sulphuric acid. The product will, however, contain 45 to 50 per cent water-soluble phosphoric anhydride.

Operations at Ajo, Ariz.

The process being carried out at present at New Cornelia is the same as that originally recommended by Tobleman, and the results which have been obtained since the beginning of operation very closely check those he obtained in the experimental plants. There have been no material metallurgical or mechanical changes.

On Dec. 1, 1919, the leaching plant had operated 928 days, having leached during that time very nearly 4,000,000 tons of oxidized copper ore (3,600,000 metric tons), the total copper content of which averaged 1.52 per cent. Practically 72,000,000 lb. of electrolytic copper has been shipped and about 38,000,000 lb. of cement copper running approximately 60 per cent in copper (33,000,000 kg. and 17,000,000 kg. respectively).

The extraction obtained is somewhat over 80 per cent, while 0.7 lb. (0.32 kg.) of copper per gross kw.-hr. has been deposited in the tank house, this latter figure being but slightly less than was originally estimated. Likewise, the amount of discard necessary to prevent fouling of the solution has been very close to that originally reported, 90 gal. (340 l.) per min.

During the spring curtailment in production it was found that apparently the longer the time of leach and the lower the corresponding acid concentration, the less would be the amount of impurities which would be dissolved and consequently the greater the proportion of electrolytic copper to cement copper produced. This, of course, is a desirable condition.

Since nearly one-third of the oxidized ore has been consumed in the leaching process, a 500-ton experimental flotation plant has been constructed to determine the proper treatment for sulphide ores. This plant has been in operation since September, 1919. It is equipped with two rod mills, 42 in. x 9 ft. 8 in. and 60 in. x 10 ft., and a Hardinge mill, 8 ft. x 36 in. (1.07 m. x 2.95 m.; 1.54 m. x 3.05 m.; and 2.44 m. x 0.91 m. respectively); also Inspiration flotation cells and Deister tables. It is desired to determine the mills, flotation cells and tables best adapted to the ore, as well as the most efficient combination of oils. About 9,000 tons of ore had been milled up to Dec. 1.

British Chemical Industry

From our London Correspondent

London, February 1, 1920.

THE outstanding feature of the past month was undoubtedly the publication of the final report of the Nitrogen Products Committee on Jan. 15. Its appearance was the signal for vigorous criticism on all sides, particularly in regard to the delay in publication, the report having been in type since May, 1919. The 2,000-odd copies available for public as distinct from official distribution will probably be snapped up very quickly, and unless a second edition is printed it will be difficult for United States and foreign interests to obtain this valuable publication. It is understood that further details regarding physical data and the work of the Research Station, of which Dr. Harker is the Director, will be published shortly, and that the negotiations for the purchase by the Brunner-Mond interests of the Billingham Haber-type nitrate factory are practically completed.

Claude Process Viewed With Scepticism

The prospects of the Claude process recently acquired by Mr. Barton are viewed with some scepticism owing to the very high pressures involved. The statements made in the report regarding costs and manufacture of oxygen have been severely criticized and are said to be inaccurate. A proposal of the greatest interest is that of setting up standards of efficiency for large users of coal and for ammonia recovery based upon practice that has been uniformly realized under good working conditions. While a scheme of this kind would have been considered Utopian before the war, the suggestion is being treated seriously and in a national spirit of co-operation.

Policy of Amalgamation Continues

The policy of amalgamation noted in my last article[1] has continued, the Castner-Kellner interests having been practically acquired by Brunner-Mond. Similar operations have been carried out in the steel, coal, glass and oil industries, and while it is realized that such collective action by the larger firms may be a national gain, public opinion still looks with suspicion upon the formation of powerful trusts with their latent drawbacks in regard to the creation of artificial prices and trade conditions. As regards the glass industry, it is interesting to note that the new factories will nearly all operate under the Owens patents—an American invention.

Chemical Trade Active—Supplies Short

The chemical trade remains very active, with acute shortage of supplies, many firms being sold out to the end of the year. Soda ash, caustic soda and many other commodities are almost unobtainable. The rubber position is very interesting, prices showing an upward tendency on account of the fall in the American exchange and the rise in the price of silver, wages being chiefly paid in the latter commodity.

The Association of British Chemical Manufacturers has just published a directory of its members printed in seven languages, and assures purchasers that goods ordered by them are actually produced by the firm in question. While this statement is quite *bona fide*, it often happens just now that manufacturers list many more products than they are actually manufacturing at the time, and "borrowing" or importation is often necessary to make up the deficiency.

Trade Union Movement Spreading Among Chemists

As regards chemical merchants, signs are not wanting that these interests also will join forces in a more powerful association than that now existing, and the chemical trade dinner on Feb. 12 will no doubt prove an excellent lubricant. The trade union movement is now spreading its net to include even such chemists as belong to the National Association of Industrial Chemists, the British Association of Chemists, etc., the proposal being to join forces with similar "professional" interests, such as those of the engineering draftsmen, bank and insurance clerks, etc.

Universities Need Funds

At the universities, the claim of the Imperial College of Science to grant its own degrees is causing much heartburning, while the lead of Manchester University is likely to be the forerunner of many other appeals for additional funds to cope with the ever-increasing influx of students.

Fuel Situation Causes Worry

The fuel situation is attracting further attention, in view of the impending shortage of petrol due to the presumed increased American requirements. It is predicted that two years hence the United States will have no petrol to spare for export and that this country must resort mainly to benzol, alcohol and motor spirit derived from the distillation of coal, if the cost of motor fuel is to be kept within reasonable limits. The work done by Ernest Bury at the Skinningrove Co.'s works on the manufacture of alcohol from ethylene and the simultaneous appointment of Sir Frederic Nathan as power-alcohol investigation officer under the Fuel Research Board give some indication of the present trend of opinion, while in engineering circles much attention is being given to the possibilities of producer-gas units for vehicles propelled by internal combustion engines.

Co-operation With U. S. Desirable

The announcement that American chemical and physical societies are to create a fund for the verification and publication of physical data and constants should lead to co-operation with the Chemical Engineering Group of the Society of Chemical Industry, which is also to devote time and effort to this essential work.

[1] See CHEM. & MET. ENG., Feb. 4, 1920, p. 200.

Value of Last Year's Exports From United Kingdom to United States

The declared value of the exports from the United Kingdom to the United States in 1919 aggregated $359,671,231, exclusive of the Birmingham consular district and West Hartlepool agency, from which returns have not been received. The total in 1918 for the whole of the United Kingdom was $143,272,830. The following increased values in 1919 are noted by consular districts: London, $144,000,000; Liverpool, $18.500,000; Bradford, $17,000,000; Manchester, $12,000,000; Dundee, $11,000,000; Nottinghom, $5,500,000; Glasgow, $4,000,000. American vessels of 1,003,258 gross tons entered the port of London in 1919, against 134,823 tons in 1918, as shown by the records of the consulate general.

Senate Debate on Dye Bill

LIVELY debate was aroused in the Senate on Feb. 25, by the introduction on the Senate floor of the dye bill. That there will be opposition to the measure was indicated by the attitude of various Republicans and Democrats. The Republican objections are based on the fact that the bill is a departure from the usual form of protective legislation. Senator Kenyon of Iowa characterized it as "a very unusual bill and a rather strange application of the protective tariff theory." Senator Thomas of Colorado, a Democrat, assured the Senate that he would speak at length in opposition to the bill. After four hours of debate the bill was temporarily set aside to make way for the Peace Treaty discussion. No definite predictions can be made as to when the bill will be taken up anew.

Senator Kenyon opposed any haste in considering the bill, as he was avowedly suspicious at finding so many of the Democrats supporting what he termed a high-tariff measure. Senator Simmons, the ranking Democrat on the Finance Committee, explained, however, that the tariff rates had been reduced by the Senate to the rates in the present law which was passed by a Democratic Congress. Senator Kenyon called attention to the fact that there were other things in the bill besides rates and Senator Watson admitted that the bill is and was intended to be an embargo measure.

Magnesite and Chemical Glassware Bills Ready but Held Back

Senator Poindexter of Washington objected to the failure of the Finance Committee to report out, as well, the magnesite and other emergency tariff bills. This led to the revelation that the Finance Committee had decided to report favorably to the Senate the magnesite bill and chemical glassware bill, but that at the last minute the committee decided to withhold the report on these bills for the present. The reason for this unusual action, it was stated by Senator Smoot, had best not be revealed at this time.

Senator Poindexter was prompted by this admission to declare that "the fact that the report which has been ordered was suspended indicates that very likely some influence—probably that which is interested in Austrian mines—is endeavoring to prevent any report at all on magnesite." He insisted that before the dye bill was presented to the Senate for a vote the magnesite bill must be on the calendar.

Smoot for Straight Protective Tariff

Senator Smoot expressed his view of the dyestuffs legislation as follows: "If I had had my way about it, the dye measure would have been a straight protective bill, providing a specific duty that would protect the dye industry of this country. I would not have put an embargo provision on it or any license system as provided in the House bill. I believe in a protective tariff principle. I would have granted a reasonable rate of protection in this bill. I would not shy at a protective duty particularly if it were limited to three years, as in this bill the embargo provision is limited, to take care of special items. This bill is limited to three years and no industry within that time could be established and begin the manufacture, say, of vat dyes required by a large majority of the cotton manufacturers of the country."

At another point in his argument Senator Smoot made the following significant statement: "I will say frankly that if I had my way about it we would have an entire revision of the tariff, but whenever the tariff is revised, whether it be up or whether it be down, the business interests of this country are unsettled. What is the use of unsettling the business of the country when we know that a protective tariff bill would not be signed at the other end of the avenue?"

Senator Watson called the attention of the Senate to the fact that the favorable report made by the sub-committee on the dye bill was unanimous and that the report made by the full committee to the Senate also was unanimous.

Knox Supports Dye Bill

Speaking in support of the measure, Senator Knox of Pennsylvania said in part:

"The forces that held the legions of civilization at bay and almost overcame them were the spectacled chemists of Germany. The whole face of the world has been changed by the creative or synthetic chemist within the last ten or fifteen years.

"If this measure was a project to invest a billion dollars of Government money for the purpose of building up an industry that would save a billion dollars a year and be a great factor in our preparedness against another destructive war I would favor it, but it is not that. The gentlemen who proposed to build up these industries will do it at their own expense, and all that they ask the Government of the United States to do is to prevent for a period of three years the importation into this country of such dyes as are made here in merchantable quantities. The proposition is reasonable. It has nothing to do with the tariff. It is not a question of tariff legislation. It is a question of wise, far-seeing preparedness, and of wise, far-seeing economy."

Plans of Dye Section, A. C. S.

The second meeting of the Dye Section, American Chemical Society, will be held in St. Louis, beginning Wednesday, April 14. At this meeting the committee on permanent organization will submit bylaws for the consideration of the Section, the approval of which, by the Section and by the Council, will be the necessary steps to the permanent organization of the dye chemists of the United States, as the Dye Division of the American Chemical Society.

The secretary asks all scientific workers in the field of dyes to present the results of their researches and experiences at these meetings of the dye chemists. Papers on the manufacture, properties or application of dyes, both of coal-tar or natural origin, will be of timely interest. Any chemist having any such scientific information ready for presentation is asked to communicate at once with the secretary, giving subject and time for presentation.

As is usual, full details of the final program, time and place of meeting can be obtained by addressing Dr. C. L. Parsons, 1709 G Street, N. W., Washington, D. C., or Dr. R. Norris Shreve, secretary, 42 Fifth Ave., New York City.

Colloquium on Electrochemical Research

Electrochemists of New York City who would like to organize a fortnightly colloquium on current researches are asked to communicate with Prof. H. C. Cooper, College of the City of New York. The organization will be informal, voluntary and mutual. Several experienced men are expecting to attend.

Iron and Steel at the A.I.M.E.

A Summary of the Discussions and Papers Read at the Winter Meeting — Blast-Furnace Flue Dust, Malleable Iron, Alloy Steel, Boiler Plate, Gun Construction and Theoretical Metallurgy Were All Treated in a Most Interesting Manner

VERY interesting sessions devoted to iron and steel metallurgy were held both morning and afternoon of the closing day of the winter meeting of the American Institute of Mining and Metallurgical Engineers held Feb. 16-19 in New York City.

A synopsis of the papers read and commented upon by members present will be given below.

Flue Dust

A discussion of the causes of blast-furnace flue dust and a new furnace-top design to prevent its production was given in a paper by R. W. H. ATCHERSON. Blast-furnace dust is troublesome at best, but the amount produced seemed to have little connection to the fineness or origin of ore charged; rather a close attention to innumerable details of furnace and accessory construction and operation has enabled the industry to reduce materially the amount of dusting in the face of finer and finer ores. Since the charge must evidently act as a filter, as uniform a mixture as possible should be placed in the furnace, to prevent almost explosive rushes of blast, breaking through a finely packed stratum. In addition, ample areas of furnace dome, out-takes and downcomers are essential. Mr. Atcherson thought that the superiority of turbo-blowers was not so much on account of the lack of pulsations (which were effectually dampened before arrival at the tuyere) as of the excellent governors capable of keeping volume and pressure uniform in the face of wide variations in steam pressure —something which governors attached to reciprocating engines could not possibly do. The author's design calls for six gas-regulating goosenecks connected to two large downcomers, the entire system intended to reduce and equalize velocity, and control its pressure—all most important factors in dust production. As to the handling of the recovered dust, he observed that wet sludge is much easier and safer to handle than hot dust, and if his idea was correct, that the content of fine coke was the root of rehandling difficulties, and therefore that wet flue dust free from coke should not disturb any function of the furnace, it was proper to experiment along the line of effecting a wet separation of these two ingredients, rather than to use the coke as a fuel for sintering, a practice which results in material most difficult to smelt because of its content of iron sili-steel"!

SINTERED VS. RAW DUST

C. A. MEISSNER, in discussion, said that in general it slows down iron production to charge raw dust, although the lines of the furnace have a large influence on the amount of flue dust produced, or the capacity to smelt it when recharged. The speaker, however, was not ready to acknowledge that either turbo-compressor or blowing engine had a decisive advantage. In spite of the formation of silicates, Mr. Meissner thought that well-sintered dust was preferable for charging, especially in case fine coke could not be first separated if the raw dust was returned, since the finest coke tended to go through the furnace unconsumed, and entering the slag, make it extremely infusible.

Semi-Steel for Shells

"Manufacture of Semi-Steel for Shells" was described by F. E. HALL. Limiting the term to cupola metal resulting when ample steel scrap is charged, he described the chemical and physical requirements of good semi-steel. Cupola practice must be most carefully controlled if uniform results are to be attained, and the author notes many precautions to be observed.

HENRY D. HIBBARD called attention to the fact that "semi-steel" was a much abused term, and while it was not ideal for cupola metal described by Mr. Hall, it seemed to be so well established that it would be desirable to retain, exclusively if possible. At present "semi-steel" might also be applied to the low-carbon product of an air-furnace, to malleable iron castings, to cast iron synthesized from steel turnings, or, according to at least two modern unabridged dictionaries, to "puddled steel"!

USE FOR RESISTANCE TO ABRASION

Attention was called to the exceptional wearing qualities of some semi-steels by R. F. HARRINGTON, who thought that real information was needed as to whether cupola or air-furnace semi-steel was superior for abrasion-resistant parts such as locomotive cross-head shoes. Mechanics generally prefer cupola semi-steel, even if physical tests appear quite similar. For determining this essentially practical point, a good testing machine should be designed. THOMAS GILMORE observed that iron for molds varied enormously in durability, and when he could get a foundryman to make him a "white iron," with the proper amount of steel in the charge and cast to have a very fine grain, the wear obtainable would compare favorably with the best manganese steel. H. A. HIXON confirmed this statement as to the wearing qualities of crusher jaws and roll shells. If these are cast against chills, with soft iron strips in the back of the casting, they would outlive the best manganese steel pieces he had ever seen.

One-Piece Gun Construction

"An Experiment in One-Piece Gun Construction" was described by P. W. BRIDGMAN. He noted that when firing a gun the interior parts of the tube are stressed at a much higher rate than the outer portions, with the result that the intensity of stress varies considerably inside to outside. For safe strength, then, considerable weight of metal is always present, which does not work to very high efficiency. By the ordinary method of keeping the interior of the gun from being strained beyond the elastic limit, thus acquiring a permanent set to the utter destruction of its accuracy, it is usual to shrink

the jackets over the tube, thus initially compressing those portions which eventually withstand the highest tension. Another scheme which was tried under his direction was subjecting a one-piece forging to heavy internal hydrostatic pressure, causing the entire tube to flow and acquire a permanent set, and at the same time a much elevated elastic limit. After such a treatment, the bore could be rifled and the barrel was ready for mounting. Practically, the chief difficulty was to devise packing tight against such excessively high pressure (100,000 lb. per sq.in.) but this problem was solved in a satisfactory manner, as described in the paper. A 3-in. gun was made in this manner, which withstood successfully extra-vigorous testing, and the scheme was being elaborated for large-scale application when hostilities ended. It would reduce the number of operations necessary in manufacture, with a corresponding reduction in time and expense, and the method of fabrication would submit the tube to far greater stresses than it would ever receive in service.

Italian Gun Manufacture

It developed in the discussion that the French were using a similar scheme in making a composite barrel. The tube was expanded into the jacket by internal pressure, rather than the jacket shrunk on by heat. Dr. F. Giolitti also said that Ansaldo Co. in Italy had made very many guns during the last years of the war on exactly the same principle as described by Dr. Bridgman, in size up to 10 in. Their two difficulties were to produce the high pressure required with rather meager apparatus, and to so arrange the equipment that different pressures would be exerted at different parts in the tube, as required by their working resistances. He described a fixture which was devised to accomplish this, consisting of a bar slightly less in diameter than the gun bore. This was inserted into the tube, and the annular space packed at the limits of the area desired to compress, then hydrostatic pressure introduced by means of small openings through the bar.

Tensile Strength of Boiler Plate

H. J. French studied the "Tensile Properties of Boiler Plate at Elevated Temperatures" at the Bureau of Standards. A short rectangular test bar was gripped in a tension machine by special long jaws, and then a tubular electric furnace placed around it. When the test bar had reached a desired stationary temperature, a stress-strain curve was obtained by means of compensated extensometers affixed to the jaws by a wide yoke spanning the electric furnace. His results were tabulated and presented as graphs, and exhibit the fortunate fact that the tensile strength and elastic limit either are maintained or are actually increased up to about 200 deg. C., a fact important in the use of such materials for high-pressure steam boilers. A more detailed summary of his results follows:

"In both grades of plates (firebox and marine) increase in temperature from 70 to 870 deg. F. (21 to 466 deg. C.) is accompanied by distinct changes in strength and ductility, viz.: (*a*) The tensile strength at first decreases a few thousand lb. per sq.in., reaching a minimum at about 200 deg. F. (93 deg. C.). This is followed by an increase up to about 550 deg. F. (288 deg C.), where the tensile strength reaches a maximum about 10 per cent greater than the normal room temperature value, after which another and final decrease occurs. (*b*) The percentage elongation in 2 in. (5 cm.) decreases rather slowly up to about 200 deg. F. (93 deg. C.), after which it drops more rapidly, until a minimum is reached at about 470 deg. F. (243 deg. C.). This factor then increases throughout the balance of the range under consideration. (*c*) The reduction in area closely follows the inflections registered in the curve for elongation but has a minimum at slightly higher temperature than the elongation. (*d*) The proportional limit at first increases slightly and shows a maximum in the neighborhood of 400 deg. F. (204 deg. C.) for the firebox plate and the highest values between 200 and 300 deg. F. (93 and 149 deg. C.) for the marine plate. It is noted that both the actual and the percentage increases are much greater in the case of the firebox grade and that the subsequent and final decrease in proportional limit for this plate takes place more sharply than in the case of the marine grade of boiler plate.

"In the case of the firebox plate, the proportional limit is maintained above its original average room temperature value of 23,300 lb. per sq.in. to a higher temperature than is the case with the marine plate. It is probable that this may be associated with the greater mechanical work received by the firebox plate."

Graphitization of White Cast Iron

In a closely written paper on the above subject, R. S. Archer reaches the main conclusions that from the available evidence A_1 for a 1.0 per cent silicon iron is probably within 15 deg. of 750 deg. C. Annealing experiments on a typical hard iron showed that the combined carbon may be reduced to 0.05 by 168 hr. at 690 deg. C., or 135 hr. at 735 deg. C., both undoubtedly below A_1. However, annealing at 785 deg. C. showed 0.5 per cent graphite after 10 hr., 0.12 per cent after 11 hr. at 735 and but 0.06 per cent after 24 hr. at 690 deg. C. Further evidence as to the temperature ranges of graphitization is furnished by reheating completely graphitized iron, re-establishing the well-supported facts that there is no re-absorption at 749 deg. C., but a considerable reversion to combined carbon at 771 deg. C.

"It therefore appears to be a well-established fact that there is a temperature above which the graphite of a completely graphitized iron will go back into solution, to be reprecipitated on cooling as iron carbide. For iron of the composition used for malleable castings (0.5 to 1.0 per cent silicon) this temperature is approximately 765 deg. C. The conclusion seems inevitable that combined carbon cannot be completely converted to graphitic carbon under conditions that cause graphitic carbon previously formed to revert to dissolved carbon and, on moderately rapid cooling, to cementite. That is, it is not possible above this critical temperature to completely convert combined carbon to graphitic carbon. If this is true, it follows that the complete conversion regularly obtained in proper annealed malleable castings must, of necessity, take place in its final stages either at or below this critical temperature.

"Whether the completion of graphitization takes place at or below a definite critical temperature is a question of importance. If, as maintained by some writers, the complete conversion to graphite takes place at this critical temperature and not below it,

such conversion must consist in the direct precipitation of an iron-graphite eutectoid. For if the conversion took place simultaneously with the formation of pearlite, there is no reason to suppose that it would not continue at temperatures slightly below the critical."

Archer calls attention to the work of Merica and Gurevitch,[1] who tentatively suggest a curve of solubility of graphite in austenite which is very close to the corresponding line for cementite in the metastable diagram applied to steels. However, speed of cooling is an important factor in the final result—in other words, white iron annealed at 835 deg. C. for a sufficient time (20 hr.) to produce equilibrium contains approximately 0.84 per cent combined carbon when quickly cooled, but 0.67 per cent when cooled under ashes. The comparatively short time consumed in passing from 835 deg. C. to temperatures well below A_1 (say 650 deg. C.) where decomposition of cementite is vanishingly slow, is sufficient to allow the formation of 0.2 per cent more graphitic carbon.

Now if it be true, as indicated from Archer's experiments, that graphitization can be initiated and completed in white cast iron at temperatures below A_1, yet on the other hand cannot be *completed* at temperatures perhaps identical with A_1, then the accepted phenomena can be satisfactorily explained as follows:

"1. With the possible exception of the initial stages, graphitization takes place directly from solid solution.

"2. Graphitization may take place from any solid solution supersaturated with respect to graphitic carbon.

"3. The evidence at present available is not sufficient to determine whether the saturation values for a solid solution on the point of precipitating graphite are appreciably different from those for a solid solution on the point of precipitating cementite. Under conditions of equilibrium, two phases are present—graphitic carbon and the saturated solid solution. Metastable equilibrium may exist between the two phases iron carbide and solid solution. Theory indicates that the carbon concentration of solutions in stable equilibrium with graphite is less than that of solutions in metastable equilibrium with iron carbide. If the available experimental evidence is considered with allowance for the effect of impurities on the solubility of iron carbide, the solubility curve of the carbide may, for practical purposes, be used to determine the conditions of equilibrium in the stable system iron graphite."

Stable and Metastable Equilibrium

A. E. White, while disavowing any intention of discussing whether graphitization takes place from cementite or from solid solution, pointed out that there was nothing unusual about the fact that it proceeded below A_1, since the stable condition at low temperatures is evidently a system containing iron and graphite. Since the tendency to approach equilibrium is always present at all temperatures, the reheating must be to a degree only sufficient to provide sufficient molecular or atomic mobility for the ever-present tendency to make itself felt. Consequently time is the only requisite for graphitization at temperatures below the critical. In the speaker's opinion the stable equilibrium diagram is delineated with far from precision, still he introduced evidence strongly supporting Archer's figure of 750 deg. C. for A_1 for standard malleable analyses.

J. V. Emmons said that graphitization below the critical can easily take place, since he had found particles of carbon occuping the precise position which free cementite had previously occupied in a piece of tempered tool steel. However, since it was extremely doubtful to him whether any solid solution could exist below A_1, any graphite should result directly from the decomposition of cementite which does exist in very large quantity.

Francis B. Foley pointed out the danger of making inferences on insufficient data, saying that another hypothesis accounted as well for the facts brought out in Archer's paper as the one that graphitization proceeded directly from solid solution. That is this: when passing Ac_{cm} the metastable cementite just born immediately breaks up into its constituents according to the reaction

$$Fe_3C \leftrightharpoons 3Fe + C$$

Lag has its well-known effects on this reaction. Quenching prevents precipitation of carbide, and martensite results. Moderate cooling allows cementite to precipitate but not to decompose, while slow cooling favors complete dissociation of the carbide. Time at temperatures below A_1 will allow all free carbon then molecularly dispersed to accumulate in microscopic masses—a condition of total graphitization. Complete graphitization above A_1 is impossible, since the reaction then goes to the left to the saturation of austenite. It follows from this hypothesis that the carbide line and its eutectic are identical with the graphite line and eutectic, a conclusion recently favored by some students of the problem.

In reply to the discussion, Mr. Archer said he still held that the weight of evidence supported the idea that graphite was precipitated from solid solution. It is important to remember that the black masses in malleable iron are not solid carbon but rather layers of graphite carbon occurring between laminations of ferrite—quite similar to eutectic structure. Another ordinary appearance is to be explained, namely, that graphite accumulations are often surrounded by a shell of ferrite, which in turn is embedded in pearlite. Now if free carbon is not an element of the solid solution, how could the graphite arrive in quantity at such a center?

Distortion on Hardening

A paper entitled "Coefficient of Expansion of Alloy Steels" was read by John A. Mathews, in which he gave the complete history and physical properties of eleven liberty motor shafts of various analyses, together with the coefficient of expansion up to 270 deg. C., a set of data unfortunately somewhat unique. It is also mentioned that moderate coefficients of expansion such as normal steels possess have not nearly so great an effect on warping during heat treatment as the skill with which the manipulations are conducted. Some special analyses with expansions about the same as ordinary carbon steels will harden entirely free from distortion or volume change, even with moderate care; others give great trouble even when quenched in dies or by machinery. "This again illustrates the fact that the coefficient of expansion, in itself, is not a primary cause of distortion in heat treatment, al-

[1] *Bulletin*, A. I. M. E., No. 151; Chem. & Met. Eng., vol. 22, p. 40 (Jan. 7, 1920).

though, in general, hardening from a temperature just about that at which the maximum contraction takes place at decalescence would tend to improve the final results of hardening so far as distortion is concerned; this practice is now in use in some progressive plants where the end of decalescence is directly determined from pieces in the furnace rather than by relying upon the reading of the pyrometer located at a more or less remote spot in the furnace."

Nickel Steel

HOWARD SCOTT presented an important contribution on the "Critical Ranges of Some Commercial Nickel Steels," a study of a series of 40-point carbon alloys of great industrial importance. Using inverse rate heating and cooling curves, he was able to plot the effect of nickel up to 4 per cent on the critical ranges of 0.40 per cent carbon steel. In general, increasing nickel decreases the width of the critical ranges on

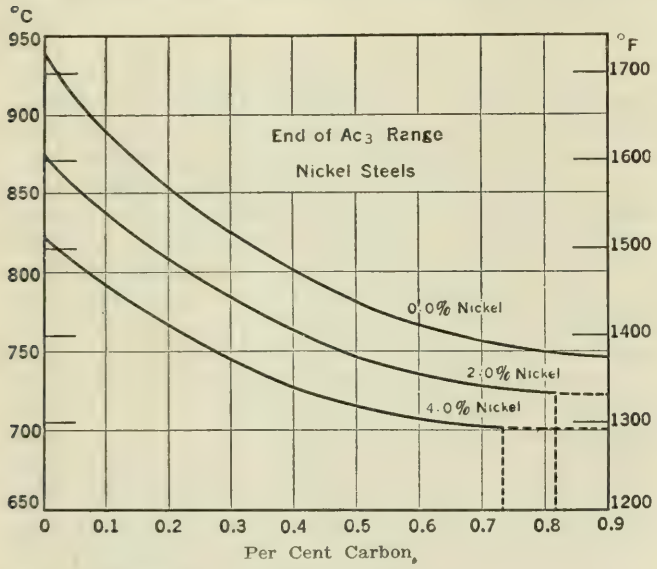

FIG. 1. EFFECT OF CARBON ON END OF Ac_3 FOR 0, 2 AND 4 PER CENT NICKEL

both heating and cooling, decreases the absolute temperature of the critical points, but with greater effect on the $Ar_{3,2}$ range. In particular, $Ac_{2,3}$ for a 40-point steel with no nickel begins at 732 and ends at 800, while if 4 per cent nickel is present the same range begins at 690 and ends at 730. $Ar_{3,2}$ for a 40-point steel with no nickel begins at 672 and ends at 745, while if 4 per cent nickel is present it begins at 587 and ends at 637 (all temperatures being closely approximate and in degrees C.). Quenching experiments show that the end of Ac_3 corresponds substantially to homogeneous austenite solution, consequently the results just quoted may be used as a basis for heat treatment with carbon-nickel steels covering a wide range.

Using in conjunction with the above data some records at the Bureau of Standards showing the effect of carbon on the Ac ranges in plain steels, and accepting the idea that a lowering of the critical ranges for carbon decreases the eutectoid composition, the curves given in Fig. 1 are presented for industrial use. In view of the steep slope for low carbon concentrations, the author emphasizes the fact that soft steels should be held within closer limits than plus or minus 5 points, since the tolerance can easily cause an error of 25 deg. in the subsequent heat treatment.

Forgeability of Iron-Nickel Alloys

A byproduct of an investigation of the magnetic properties of iron-nickel alloys was presented by T. D. YENSEN, in a paper of the above title. He found great difficulty in working pure iron-nickel alloys at ordinary forging temperatures, consequently in order to get a usable magnetic alloy, a composition had to be worked out which could be produced in commercial shapes. Whereas the degree of forgeability of a material depends on the relative strength of the crystalline and the intercrystalline—or amorphous—material, the forgeability of an ingot or casting can be ascertained only by actually attempting to deform the material, either by forging or rolling, or by tensile test. Metallography has not yet reached a stage where an inspection of the microstructure will give any definite information in this respect. Aluminum, carbon, magnesium or silicon was found to have little or no effect upon the forgeability, but the fact that manganese and titanium in amounts equal to 2 per cent of the lesser binary constituent transform iron-nickel alloys from non-forgeable to forgeable alloys means that these elements have the ability to strengthen the amorphous material that is generated between the crystals to such an extent as to make it stronger than the crystalline material.

C. G. FINK said that he investigated the same properties when developing a compound wire with a copper shell over a nickel-iron core. The two had to have about equal ductility so they would deform alike during wire-drawing. All his alloys containing 26 to 60 per cent nickel were very hard, and required continual annealing, but when the most extreme care was used to prevent carbon entering the alloy—even that amount usually introduced by an Arsem "vacuum" furnace—the same alloys could be made so soft they could be whittled with a knife. All the alloys contained manganese, which was necessary for the requisite tenacity.

CRITERION OF FORGEABILITY

ZAY JEFFRIES pointed out that Dr. Yensen's paper needed correction in that the condition of forgeability was not solely the possession of a strong crystalline cement, but, in addition, it should be strong enough to force the crystals to bear strain, and the latter in turn must be capable of being deformed. Thus, lead is forgeable, but not ductile—that is, it cannot be drawn through dies. In this case the cement is not strong enough to hold together and transfer the load to the deformable crystals. Fine grained chromium metal, again, has a very strong cement, but the metal cannot be forged because the crystal cannot be deformed. The rate at which the stress is applied has a great part in determining the apparent mobility of crystal as related to its cementing films, as has often been pointed out before.

Crystallography of Iron

"Microstructure of Iron and Steel at High Temperatures" was discussed by H. S. RAWDON and HOWARD SCOTT, in a profusely illustrated paper, difficult to abstract, but which we hope to publish in full. One of their principal conclusions is that heating *in vacuo* (using a modified Rosenhain furnace) pronouncedly decarburizes both hyper- and hypo-eutectoid steels, an experimental result at complete variance with Dr.

Henry M. Howe's proposition that excess constituent is extruded by austenite crystals to their surfaces.

The various reasons advanced by Dr. Howe to support this hypothesis were reviewed by E. E. THUM, who pointed out that a pseudo-mechanical "elbowing" action did not explain the observed phenomena of movement and agglomeration of insoluble ferrite or cementite as well as the incessant solution and reprecipitation continuing at all times, a balanced action producing equilibrium between any solvent and its solute. In one case only, which Dr. Howe substantiated with micrographs, was the solution theory at fault. That was that pro-eutectoid material tended to line the walls of cavities, either natural or artificial. Even in view of this case Mr. Thum felt that the true test of an "elbowing" action would be evidence that an insoluble particle, like a sonim, had been bodily moved solely by heat treatment.

Drs. F. GIOLITTI and Z. JEFFRIES both said that elbowing of solid materials was to their minds very doubtful, and that they had never seen any evidence that would point to transportation *en masse;* in fact, definite trials at temperatures up to 1,300 deg. C. had caused no bodily movements in the slag. The latter speaker said that some small movement might be caused by the fact that grain boundaries ordinarily contain inclusions, and the crystalline growth is often obstructed by such particles, especially if there were many of them present. Of course some movements in ferrite and cementite were not due to diffusion—for instance, spheroidizing of cementite was doubtless a surface tension effect. But the apparent habitat of pro-eutectoid material at grain boundaries was due in greatest part to the fact that the first portions to separate tend to draw like material to themselves, correspondingly impoverishing the surrounding region.

Changes in Iron at a Blue Heat

ZAY JEFFRIES presented the report of a National Research Council committee on the "Physical Changes in Iron and Steel Below the Thermal Critical Range." After an extended review of the literature on such aspects of the subject as the variation in tensile and electrical properties, the recovery of elasticity after overstrain, the effect of working at blue heat, aging, and low-temperature thermal evolutions, the author concludes that the best substantiated phenomena are well explained by assuming a low-temperature allotrope in iron.

More than a little opposition to this view was apparent, however. HOWARD SCOTT was under the impression that many phenomena simulating the properties of allotropes could be ascribed to a slow but long-continued precipitation of cementite, held at low temperature in metastable solution, an action similar to the aging of duralumin. Blue brittleness and unusual impact values, on the other hand, might be due to a very slight solubility of cementite in ferrite—absolute and complete insolubility is unlikely.

F. C. LANGENBURG also doubted if blue brittleness was more an evidence of allotropy than an inherent property of free ferrite. Honda had found a magnetic change in cementite at low temperatures, which could easily be responsible for many peculiarities in brittle steels—for instance, the improvement under impact of nickel-chromium steels after quenching from 600 deg. C. may result from a considerable content of such carbides.

R. S. ARCHER pointed out that although the α, β and γ states of iron had been established by a study of the physical properties, allotropy involved molecular rearrangement. Such molecular arrangements in nature are known to be simple, yet there were not so very many simple arrangements possible. Most of the evidence regarding elastic recovery after strain could be harmonized with Beilby's amorphous theory, especially since the phenomenon was by no means limited to iron. If a ferrite crystal be overstrained to the point where slip occurs at one plane, the freshly formed amorphous material along that slip plane is very weak and has a low adhesion—which is the reason why slip can take place by stages. This temporary great mobility at any rate passes quickly, and after a time the amorphous phase hardens and the adhesion becomes very great. If, however, the deformation takes place at about 300 deg. C., the hardening of the amorphous phase is much more rapid, with the result that the stress occurs in parallel planes. An equal deformation at this temperature is consequently accompanied by the development of a largely increased number of slip planes, a largely increased proportion of amorphous material, and a correspondingly enhanced brittleness.

F. N. SPELLER asked whether the so-called "crystallization of steel in use" was not another occurrence within the scope of this investigation. It at least apparently involved the formation of considerable amorphous material in such important grades as soft and medium steels. His experience indicated that there were other causes than alternating loads for "crystallization" failures, since granular fractures occurred at places well removed from loci of maximum strain.

W. E. RUDER agreed that magnetic aging was a peculiar fact which a very extensive investigation had failed to explain. The only clue discovered to date was that an annealing in hydrogen nearly but not entirely prevents magnetic aging in low-carbon steels. In such a complex series of evidence, however, he felt that it would be extremely surprising if one simple fact could be discovered which would completely explain it all.

S. L. HOYT argued that if allotropy were the material cause of some discontinuities—such as, for instance, a slight break in the rate of expansion of steel at a blue heat—the fact should be studied in the light of what we know about allotropy. In other words, the transformation should be reversible, and give evidence of lag, especially owing to sluggishness of atomic movement at low temperature. Thus, extensive tests on complete cycles of heating and cooling would be needed to establish Dr. Jeffries' contentions.

The author in reply acknowledged that Langenburg's point was well taken; in fact, he did not contend that blue brittleness of Ni-Cr steels (the so-called Krupp Krankheit) was due to a low-temperature allotrope. However, the peculiar variation of tensile properties with heat cannot be due to a carbide transformation, since they occur in pure iron as well as in steels. Even admitting that the general effect of stress and time is to produce slip bands and subsequent failure by virtue of a local, irreversible deformation, Dr. Jeffries felt that the quantitative effect in iron strained at blue heat was enormously greater

than could be ascribed to a theory similar to that adopted by Archer. In this connection he also called attention to a hypothesis advanced by Radcliffe Furness, that if ferrite goes to grain boundaries at temperatures above the low critical, then the same tendency will persist in sorbitic ferrite at a lower temperature. This tendency, being satisfied to a minute degree, would produce thin films of ductile ferrite at boundaries of sorbite grains, shells which though ductile are much weaker than the kernels they surround. Consequently intracrystalline fracture in such steels will simulate brittleness.

Added Life for Factory Roof Timbers*

It is only necessary for the investigator to view the roof trusses of a number of buildings housing chemical apparatus to note the rapid decay caused by high humidity and the inroads of acid fumes. It is believed that a number of the preservative treatments which are suggested in the following paragraphs, if applied either during construction or after erection, would mean increased returns to the company through added life given to the wood members.

The steeping process of preserving timber consists merely in soaking the timber in a water solution of a preservative such as zinc chloride, sodium fluoride or mercuric chloride. Thoroughly seasoned wood is used and left in the solution one day for each inch in thickness and one additional day.

After treatment the timber should be air dried before using. Zinc chloride attacks lead paint, but is very desirable otherwise. Mercuric chloride is very effective, but is poisonous and has a decided corrosive action on steel, so that steel tanks cannot be used with it. Sodium fluoride does not attack paint, is not corrosive, and in most other respects is very desirable.

Timbers may be coated with coal-tar creosote by brush treatment, by dipping in hot oil from 5 to 15 min., or the hot and cold bath method. This last method consists of submerging the lumber in hot oil for several hours and then either allowing the oil to cool down slowly with the wood in it or plunging the wood into cool oil and leaving it for several hours. This method of preservation is objected to by some insurance companies as a fire hazard, but whether or not it really does add greatly to the inflammability of wood is a debatable question.

Although pressure treatments are the most expensive, they are the most effective, because they result in the greatest absorption and penetration of preservatives. Roof planking should receive 8 to 12 lb. of creosote per cu.ft., or ½ lb. of the salt if zinc chloride is used. Such treatment should add at least 20 yr. to the life of roof planks.

The effectiveness of treating timbers depends upon maintaining a complete envelope of treated wood around the untreated interior of the piece. If this treated layer is broken through, decay can enter and destroy the untreated interior in spite of the treated outer layer. For this reason lumber should be cut to final dimensions before treatment. Whenever it does become necessary to cut into treated timber, the untreated wood exposed by cutting should be given two fresh coats of creosote or some other preservative.

American Institute of Baking

The American Institute of Baking, founded by the American Association of the Baking Industry, has begun work in Minneapolis under the direction of Dr. H. E. Barnard, assisted by an advisory committee of the National Research Council and in co-operation with the Dunwoody Institute. Dr. Barnard has been connected with the State Board of Health of Indiana for nearly nineteen years and was Federal food administrator of that state during the war.

For thousands of years bread-making has been a craft rather than a science, and in all its essentials and in many of its details it has remained practically unchanged for ages. The attempt is now to be made to make bread-making a science, or at least to found it on science. Some of the larger baking companies have already tested the value of science as applied to their business, and one of these companies, using more than a million barrels of flour a year, has introduced methods leading to great economies in its work. It was found that by furnishing the yeast with certain stimulants and special chemical foods a saving of some of both the flour and sugar formerly consumed by the yeast during its growth was made. This is not only a saving to the baker but also a conservation of valuable human food materials without any diminution in the quality or food value of the bread.

However, but few of the 28,000 bakers in the United States are in a position to conduct scientific experiments or to have them conducted for them separately. Of these 28,000 bakers, only 7,500 use more than 50 bbl. of flour a month, while only 2,500 use more than 200 bbl. a month. For each one of these bakers to try to engage in scientific research would obviously result in a waste of effort even if the expenses could be met, but by working in co-operation, as now arranged by the new Institute of Baking with the scientific aid of the specialists on food and nutrition, agriculture, chemistry and physics of the advisory committee of the National Research Council, all of these bakers can get the advantage of a strong scientific effort for the rational improvement of their methods.

War Zone Reconstruction

The European technical press estimates that there was over 3,000,000 tons of copper thrown from artillery in France and Belgium, and 100 tons of steel per acre (250 tons per hectare) buried in large districts where heavy bombardment persisted. One-third of the total copper and a much larger percentage of the steel will be recovered.

Reconstruction in the French steel and iron industry will require from eight to ten years, mainly because the towns in which the plants are located were 98 per cent destroyed. While nothing has been done toward clearing away the débris around the large steel plants, out of the 500 smaller metal-treating and fabricating plants of the regions 47 per cent have resumed operation, employing, however, only 14 per cent of the original working force.

The damage in the Lens coal district is estimated as 80 per cent of the total valuation of the property. Before pumping can be commenced the holes in concrete shaft linings and tunnels must be discovered and restored, as no headway can be made against the seepage in the moist territory surrounding until this is done.

A Contribution to the Study of Flotation

An Analysis of Circumstances Connected With a Paper by H. L. Sulman in the "Transactions" of the Institution of Mining and Metallurgy—Doubt Cast on the Reliability and Sincerity of the Contribution

BY AN OCCASIONAL CONTRIBUTOR

THERE has recently appeared in the *Transactions* of the Institution of Mining and Metallurgy a paper by H. L. Sulman entitled "A Contribution to the Study of Flotation,"[1] which, because of the many circumstances surrounding its origin, requires more careful and dispassionate scrutiny to give it the value in technical literature which should be attached to it than any other paper appearing in recent years.

Mr. Sulman is a past president of the Institution of Mining and Metallurgy and in the part which he has taken in the discussions at the Institution's meetings he has shown himself to be an astute student of science. But he has also occupied another relationship to the development of science and industry, in that he has been engaged in the invention and patenting of processes of ore-treatment and is now and for years past has continuously been in the employ of one of the most widely known companies which has patented and exploited concentration processes.

The greatest of all Teachers long since uttered a truth of universal application when He said: "No man can serve two masters, for either he will hate the one and love the other, or else he will hold to one and despise the other. Ye cannot serve God and Mammon."

Let us look into the facts in the case and, if we can, ascertain which master Mr. Sulman is serving at this time.

H. L. Sulman and H. F. K. Picard wrote a treatise on flotation concentration some years since. In the preface of the first edition of his work entitled "Concentration of Ores by Flotation," published in July, 1912, Theodore J. Hoover, now professor of mining and metallurgy at Leland Stanford Junior University, states:

> To H. Livingstone Sulman and Hugh F. K. Picard, of the firm of Sulman & Picard, I am indebted for many ideas absorbed from them through three years of pleasant professional association, during which time they were consulting metallurgists to the above company (i.e., Minerals Separation, Ltd.). They have in preparation a book on the "Theories of Concentration Processes Involving Surface Tension," which will be a work of high scientific merit. I have endeavored, I hope successfully, not to trespass on any new and unpublished ground, the announcement of which rightfully belongs to them; further it is not my desire to present the subject in so profound a manner as they will do, deeming it of considerable more use to engineers to leave for another occasion the discussion of mathematical and physical laws involved.

In the third edition of the same work, published in 1916, Mr. Hoover says on pages 257 and 258:

> G. D. Van Arsdale has given some excellent results of his investigation of surface films and contact angles, and brings the solution of a number of hitherto unsolved problems measurably nearer. Without detracting in the least from the merit of his work, or in any way depreciating his discoveries, it is only right to say that these things and many others of equal, if not greater, importance to science have been discovered and clearly and definitely quantified by H. L. Sulman and H. F. K. Picard. As mentioned in the preface to the first edition, they have for years been working on the physical factors involved in flotation processes, and have had for many years a voluminous work completed and ready for publication.
>
> This manuscript is among the archives of the Minerals Separation, Ltd., who adopt the attitude, in this case, of censors. If it is the intention of the company to regard themselves as being in a state of war against the whole metallurgical industry, there might be some justification for an embargo on the publication of scientific information; but they have received at the hands of the state a valuable monopoly in a great industry, against which they should not wage war; but, on the contrary, they should act with frankness and candor toward those with whom they seek to do business, and from whom they expect to draw the revenue assured to them by their monopoly.

Mr. Hoover's references to this book indicate such familiarity with its contents as could only come from a detailed and continued study of it.

In the *Mining Magazine*,[2] in an editorial upon the presentation of Mr. Sulman's paper to the Institution, we read in part as follows:

> And here it is appropriate for us to say that the reading of the paper has been delayed many years, owing to the litigation in connection with Minerals Separation's patents. In the meantime other investigators have published views and theories, and they and their friends have prided themselves that they knew more of the physics of the process than the original patentees. But though Mr. Sulman never wrote anything on the subject, he was immersed in study and research from the beginning. A dozen years ago the present writer saw a book[3] which Mr. Sulman had ready for publication. All the diagrams figuring in the paper were in this book, as well as the word "hysteresis," which Prof. Boys said the other night was invented three years ago. Naturally much research has been done since then, and the services of the principles of colloid chemistry and adsorption have been requisitioned. But the fact remains that Mr. Sulman was a pioneer in the scientific study of the physics of the process as well as an inventor of the successful process.

The *Bulletin* of the Institution of Mining and Metallurgy for January, 1920, is given up largely to a discussion of Mr. Sulman's paper and to a paper by Walter Broadbridge entitled "Froth Flotation—Its Commercial Application and Its Influence on Modern Concentration and Smelting Practice."

The comments upon the Sulman paper vary from the laudatory to the most sharply critical.

Sir Thomas K. Rose, whose "Metallurgy of Gold" has long been considered a classic and an authority, commented that "he had heard that Mr. Sulman had written a book on the subject, ten or twelve years ago, which had never been published, and that most of the paper was contained in it. He wished he could have seen that twelve years ago, because by this time he might have been in a position to discuss the matter usefully."[4]

[1] *Bulletin* Institution of Mining and Metallurgy, November, 1919.

[2] *Mining Magazine*, December, 1919, p. 323.

[3] This was probably a copy of the treatise referred to in Hoover's "Concentration of Ores by Flotation."

[4] *Bull.* I. M. M., January, 1920, p. 10.

Sir Thomas also commented upon the fact that the paper should have contained some data upon which is based the revelation that cassiterite has been proved to be concentratable by flotation.

E. Hatschek reviews the Sulman paper *in extenso* from the standpoint of the physicist,[5] and differs from many of the author's conclusions. He states, in italics, that the *"facts are incorrectly stated in every essential particular"* (p. 75) as regards the fundamental phenomenon, cataphoresis. (*Ibid.*, p. 19.)

He further comments: "Considering the large amount of theoretical matter of an elementary nature which Mr. Sulman has included in his paper, there is a surprising absence of reference to recent work which has the closest bearing on several of the issues raised in it."

In an editorial in the *Mining and Scientific Press*,[6] T. A. Rickard says:

> We think it proper to record a strong protest against Mr. Sulman's unscholarly failure to make the customary references to previous writers on his subject. In the concluding paragraph of the paper he excuses himself for his lapse of good manners by presenting a bouquet to his business associate, John Ballot, until recently the chairman of Minerals Separation, Ltd. Mr. Sulman describes his partner as "one of the original inventors" of the process, when it is well known, on the evidence of Mr. Ballot himself, that he merely instructed a member of his staff, A. H. Higgins, to make a series of experiments, ringing the changes on various proportions of oil, rates of agitation, and so forth, the consequence being to confirm the results obtained a year before by F. A. Beauchamp and Wilton Shellshear in the Central mill at Broken Hill—results of which Mr. Ballot must necessarily have been aware, because his own representative, G. A. Chapman, was on the spot and participating in the Australian experiments.

In replying to the criticisms of his paper Sulman says:[7] "Mr. Hatschek is correct as to my faultiness in matters of form. I am aware that many references are lacking; as before stated, these will be inserted in any reprint of the paper. I also feel that apologies are due for several misprints and for one or two obvious slips; I can only urge that the paper was written under considerable pressure as to time, and that my reading of the proofs was similarly hurried."

Sulman Scientist a Sulman Protagonist?

All of which tends to but deepen the mystery. As has been previously stated, it is known that many years ago Sulman and Picard had "completed and ready for publication" a book on "Theories of Concentration Processes Involving Surface Tension," "which will be a work of high scientific merit."[8] Yet in 1919 we find a paper coming out under the signature of Sulman alone and in a form which Mr. Sulman admits is occasion for apology because of the hastiness and unworkmanlike shape in which it is presented.

It is inconceivable that it is Mr. Sulman, devotee of science, who has not found the time in a dozen years in which to prepare his paper according to the conventions observed by scientists in the presentation of "contributions" to knowledge.

Is it not possible that it is Mr. Sulman, follower of the law and the profits, who has answered an emergency call to publish something promptly which will answer the accusation that his employers have steadily placed a brake upon the spread of knowledge and the development of science? And is it not possible that Mr. Picard, who we have been assured was a co-author with Mr. Sulman in the writing of a treatise prepared years ago, finds it impossible or impolitic to appear as co-author of the paper now hurriedly published?

That these things may be true is suggested by the fact that these gentlemen have for years been debarred from publishing their original scientific treatise by their employer, Minerals Separation, Ltd., which company has been litigating their patents for many years. The suppression of the publication of what is alleged to be a purely scientific treatise strongly suggests that the claims which Minerals Separation, Ltd., has been attempting to establish in the courts have in fact the insecure foundation which has been credited to them by the American mining industry. For if they could stand the full light of science there would never have been any reason for suppressing a scientific discussion of the physical basis of flotation.

American Branch of Minerals Separation, Ltd., Under Federal Scrutiny

The Federal Trade Commission of the United States of America has had the American branch of Minerals Separation, Ltd., under most careful scrutiny. George L. Nye, special counsel for the American Mining Congress in the Federal Trade Commission inquiry, at the St. Louis Convention of the American Mining Congress points out[9] that the British employers of Mr. Sulman were throughout most of the World War maintaining commercial relations with Beer, Sondheimer & Co., and taking all necessary crafty steps to see that that German company which was on the British blacklist should reap the full benefits of its part ownership and management of Minerals Separation's patents. This should be a shock to all good Britishers and be given most serious consideration by the loyal British members of the Institution of Mining and Metallurgy.

Mr. Nye also calls attention to the fact that the license contract issued by Minerals Separation, Ltd., to users of the process covered by its patents "provides that the licensee shall not, without the consent of licensor, communicate any details connected with the working of any of said inventions, modifications, additions, or improvements to any third party. This again emphasizes the restraint imposed by Minerals Separation, Ltd., upon any dissemination of information except under its direction and control. This restraint upon the spread of knowledge is not only adverse to the public interests but is certainly against public policy."[10]

May not this well merited criticism of the suppression of knowledge by one chosen to represent the whole American mining industry, and the investigation by the Federal Trade Commission explain the panic to publish something sounding very scientific, which led to the hasty and slovenly preparation of the Sulman paper?

May not the same necessity for camouflage also explain the appearance in the *Bulletin* of the Institution for January, 1920, of a paper by Mr. Broadbridge, general manager for Minerals Separation, Ltd., which, like the Sulman paper, creates the impression that information of value is being furnished when it is not, and which errs fully as flagrantly as does Mr. Sulman's paper in not giving proper credit to the various engineers who have contributed to making flotation concentration an established art?

The Effect of Nitrogen on Steel

A Résumé of the Important Literature on Amount of Nitrogen in Various Classes of Steels, Its Method of Occurrence and Effect on Physical Properties, Together With Some Recent Experiments on Its Action During Heat Treatment

BY GEORGE F. COMSTOCK* AND W. E. RUDER†

THE subject of the influence of nitrogen on steel is one that has awakened scant interest among metallurgists until quite recent years, because in spite of the undoubtedly strong effect of this element when presented in small amounts in iron, the amounts actually found in commercial products are generally so excessively minute that even their determination is difficult and the assignment of definite effects to them is nearly impossible in the presence of so many more potent disturbing factors. Perhaps in no other branch of ferrous metallurgy is the conflict between the theorists or laboratory workers and the practical men more pronounced; for in laboratory tests nitrogen appears to be one of the most detrimental of all impurities in steel, while in commercial practice it has not been easy to show any consistent effect. An outline of the published researches on nitrogen in steel will be given below to show the state of our knowledge of the subject at the present time.

EARLY WORK

One of the earliest references to this subject is a paper by A. H. Allen in the *Journal*, Iron and Steel Institute for 1880 (No. 1, p. 181), where an analytical method for nitrogen in steel is given, and results are quoted that indicate its presence in all ordinary steel. The effects of nitrogen were not described in this paper, but in 1887 an article by H. N. Warren in *Chemical News* (vol. 55, p. 155) mentioned the fact that great brittleness could be caused in steel by nitrogen absorbed during heating to a bright red in an atmosphere of ammonia. It was stated that only 0.5 per cent of nitrogen would make steel bars so brittle as to break when dropped from a height of 6 ft. In 1889 H. Tholander published an article in *Jernkontorets Annaler* (vol. 43, No. 7) discussing the practical effects of nitrogen in commercial steel. He found 0.012 to 0.022 per cent nitrogen in bessemer "ingot iron," and 0.005 to 0.013 per cent in open-hearth steel plate, stating his opinion that the difference in quality between these grades of steel was largely due to the difference in nitrogen content. He also suggested that the damage done by overblowing bessemer metal was due to nitrogen absorption rather than to over-oxidation.

In regard to the form in which nitrogen exists in steel, G. I. Fowler in 1894 published an article in *Chemical News* (vol. 68, p. 152) stating his agreement with an earlier writer, Stahlschmidt, that only one nitride of iron, Fe_2N, exists. Two years later a "Note on the Presence of Fixed Nitrogen in Steel," by Harbord and Twynam, appeared in the *Journal*, Iron and Steel Institute (1896, No. 2, p. 161), recognizing that nitrogen may be both mechanically occluded and chemically combined in steel. They investigated the presence in steel of Mn_6N_2, which compound is formed when manganese is heated in nitrogen, but could find no proof of its occurrence in steel. Good average steel was found to contain from 0.006 to 0.017 per cent nitrogen, and no difference in the content of this element was found between bessemer and open-hearth steel, although crucible steel was found to contain less. No connection was found between the nitrogen content and the quality of the steel, although one rail which failed from a flaw was found to be unusually high in nitrogen.

BRAUNE'S PUBLICATIONS IN 1905

After this preliminary work, no more important papers appeared on nitrogen until 1905, when H. Braune published several articles (*Stahl und Eisen*, vol. 25, p. 1,195; *Revue de Metallurgie*, 1905, p. 497; *Jernkontorets Annaler*, vol. 59, p. 636) discussing the influence of nitrogen on iron. He found that nitrogen increased the strength but decreased the elongation of iron. From 0.02 to 0.062 per cent was found in commercial steels. In general it did not have much effect on low-carbon wrought-iron; but in ingot metal or steel 0.035 per cent nitrogen was enough to destroy the elongation when the carbon was high, 0.045 per cent destroyed the elongation of 0.50 per cent carbon steel, and 0.06 per cent made soft acid bessemer steel brittle. Nitrogen was found to affect the magnetic properties the same as carbon. It was thought to occur as the nitride Fe_8N_2 in solid solution in ferrite. When 0.075 per cent nitrogen was present, the grain-size was reduced to one-tenth its normal size, and a brittle substance began to appear at the boundaries. With 0.2 per cent, the steel had a pearlitic appearance, or, as discussed by Le Chatelier, it may be said to show Neumann's lines which were often found by Osmond in brittle steel. Braune stated that steel will absorb nitrogen in every metallurgical process with high temperature, basic slag, and reducing conditions or in presence of carbon. He described a case where nitrogen produced brittleness in Lancashire hearth-iron made from pig coming from a blast furnace that produced large quantities of cyanide.

BRAUNE'S WORK CRITICIZED

This work of Braune was rather severely criticized in several quarters, Pourcel in the *Revue Universelle des Mines* (vol. 15, p. 229) contending Braune's statements were not probable, that nitrogen would be absorbed or retained in steel made in the oxidizing atmosphere of both bessemer and open-hearth processes. Grabe in *Revue de Metallurgie* (vol. 5, p. 353) and Petren and Grabe in *Jernkontorets Annaler* (vol. 60, p. 1) maintained that Braune's chemical methods were incorrect, giving too high results for nitrogen. They conclude that the minute percentages of nitrogen actually existing in

*Metallurgist, Titanium Alloy Manufacturing Co.
†Metallurgist, General Electric Co.

commercial steels had no influence on mechanical quality.

The first of the *Carnegie Scholarship Memoirs* (1909) of the Iron and Steel Institute contain some notes on the "Influence of Nitrogen on Steel," by Walter Geisen. He states that the elongation of steel entirely disappears with an increase in nitrogen from 0.037 to 0.041 per cent, and that hard steels are more sensitive to nitrogen than soft ones. The superiority of crucible steel was explained by its low nitrogen content, and vanadium's value in steel was thought to be due to its removal of nitrogen.

Nitrogen and Phosphorus in Boiler Plate

The next important reference to nitrogen in steel is C. E. Stromeyer's work, published in the *Journal*, Iron and Steel Institute (1909, No. 1, p. 404) under the title "Aging of Mild Steel and Influence of Nitrogen." In his exhaustive investigation of the effect of aging on steel, no reason was found by tests for the occasional brittleness of plates failing in service, except the influence of phosphorus and nitrogen. The worst steels were found to contain either the highest nitrogen or phosphorus, or both, and nitrogen was found to have a much greater effect than phosphorus. Results from cold bend tests by impact on plates previously bent at a blue heat were found to depend distinctly on nitrogen and phosphorus, and it was advised that these elements be reduced as low as possible in high-class boiler steels. The following suggestive formula for the tenacity of such steel in tons per sq.in. is advanced by Stromeyer:

$$T = 17.2 + 35C + 10Si + 2.5(Mn - 1.72S) + 30P + 300N$$

In another paper, before the British Institute of Naval Architects in 1910, the same author stated that the sum of the phosphorus content plus five times the nitrogen content should not exceed 0.08 per cent in good mild plate steel. He also mentioned some boiler plate that appeared very bad in tests, although containing only 0.047 per cent phosphorus; but it had 0.0123 per cent nitrogen, over twice as much as was found in good mild plate steel.

Stromeyer's conclusions were, however, not accepted in some quarters, Saniter especially throwing considerable doubt on them in discussing the paper. It was pointed out by him that all Stromeyer's steels were quite pure, and others had found good steel to contain more nitrogen than was shown by his samples. Furthermore by not considering the samples with over 0.06 per cent phosphorus, he showed that Stromeyer's results on bending did not really bear much relation to the nitrogen contents, or to the phosphorus plus five times the nitrogen, which was the merit figure used by Stromeyer.

Nitrogen's Influence on Steel

An interesting letter in Metallurgical & Chemical Engineering (vol. 11, 1913, p. 121) by "E. D. A." entitled "Nitrogen, Its Influence on Steel," also discusses these results. This letter admits that in general nitrogen promotes brittleness in steel, although the manner in which this is effected is not known. In various steels the nitrogen content was found to run from 0.003 to 0.014 per cent. Open-hearth steels averaged lowest in nitrogen, electric steels next, and one bessemer rail showed the most. One electric steel treated with ferrotitanium showed less nitrogen than the untreated average. In comparing actual physical test results with Stromeyer's merit figures derived from the nitrogen contents as mentioned above, the latter were found to be of small significance, as two out of the three best steels stood lowest in regard to the phosphorus and nitrogen merit figure. Merit figures are thus concluded to be not uniform or consistent.

Suppression of Transformations by Nitrogen

Probably the most important work that has been done along theoretical or laboratory lines on nitrogen in steel is that by J. H. Andrew, published in two papers by the Iron and Steel Institute. One of these was on "The Influence of Gases Upon the Critical Ranges of the Iron-Carbon Alloys," published in the *Carnegie Scholarship Memoirs* (vol. 3, 1911, p. 236); the second was entitled "Iron and Nitrogen" and appeared in the *Journal* (1912, No. 2, p. 210). Andrew found that heating and cooling in ammonia gas had a marked effect on the critical points of steel, which effect was overcome by reheating a number of times *in vacuo*. The effect was explained by his finding that while CO, CO_2 and hydrogen had no action on the critical changes in iron, 0.3 per cent nitrogen entirely suppressed them. In a 0.60 per cent carbon steel, 0.25 per cent nitrogen lowered the Ar_1 point decidedly. The embrittling effect of nitrogen on steel was considered due to the tendency of the dissolved nitride to retain iron in the gamma state and the carbide in solution. Only a very small amount of nitrogen is needed, and the nitride is not unstable, remelting or prolonged heating *in vacuo* being necessary to extract it all. Iron nitride was considered by Andrew to prevent the coalescence of the iron molecules at the critical point, thus retarding the changes. Iron and iron-carbon alloys were found to absorb small amounts of nitrogen when melted under a high pressure of the gas, so that ammonia is not essential to this absorption.

Needles, Neumann's or Slip Bands

Photomicrographs of nitrogenized iron are given by Andrew, showing needles called Neumann lines, and near the edges of the sample a pearlitic structure with a dark needle-like constituent and a pale yellow substance surrounding it. A quickly cooled specimen with 0.16 per cent carbon, nitrogenized while molten, showed a white constituent like cementite. This was stated not to be pure nitride or carbide, because the sample showed neither critical points nor carbide change; but it was considered a solution of iron-nitride in iron. Dr. E. Colver-Glauert, in a rather theoretical discussion of Andrew's paper, stated that he considered the needles or cementite-like substance to be nitride of iron, and he believed the carbon was expelled from the steel, probably as a cyanide, during the nitrogenizing treatment, and was not dissolved in the steel or nitride.

A German investigation of nitrogen in steel by B. Strauss (*Stahl und Eisen*, 1914, vol. 34, p. 1,814, and *Iron Age*, 1916, vol. 97, p. 432) resulted in the conclusions that it raised the elastic limit and tensile strength, but reduced the ductility; also that it impaired the magnetic properties, raising the hysteresis and coercive force, and lowering the permeability. This writer thought the needles or Neumann lines in nitrogenized iron were slip bands due to brittleness of the iron caused by solution of nitrogen in it, the slips being produced in polishing or cutting the specimens. Pearlitic and other structures were described due to the combination of nitrogen with carbon in steel, and it was stated that the nitrogen was quickly given off from the steel by annealing in air, hydrogen, or vacuum.

Others × 400.

A voluminous treatise on "The Occurrence and Influence of Nitrogen on Iron and Steel," by N. Tschischewski, appeared recently in the *Journal*, Iron and Steel Institute (1915, No. 2, p. 47). The author considered that the injurious influence of nitrogen on the mechanical properties of iron had then been firmly proved. He found that it increased hardness, reduced elasticity, and caused cold-shortness in steel; and that bessemer steel contained five times as much nitrogen as open-hearth. Metallographic work on iron nitrogenized in the laboratory with ammonia showed a very brittle outer film, found to contain 11 per cent nitrogen, which was considered to be the compound Fe_2N. A hard, less brittle layer below was considered $Fe_{12}N$, with 2 per cent nitrogen. The needles in the interior were believed to be this compound. Different structures were found due to different rates of cooling: needles, or spots like a eutectic, or even massive like martensite when quenched. Nitrogen was said to be indistinguishable under the microscope when present in less quantity than 0.05 per cent. Wire with 0.3 per cent nitrogen was very brittle.

In the discussion of this paper both Stead and Stromeyer agreed that bessemer steel contained more nitrogen than open-hearth. It was suggested that the form in which nitrogen occurred in the steel, whether uniformly distributed or around the grains, would have an important influence on its effects on the properties; also the nitrogen absorbed from ammonia might have a different effect than that added directly from air as in a converter. Stead considered that temperature conditions must affect the absorption of nitrogen in practice. Pourcel considered this paper impractical, as ordinary steel never contained over 0.015 per cent nitrogen, and higher contents than this, as sometimes found in titanium steels, never did any harm. Even nitrogenized steel showed only about 0.015 per cent nitrogen after remelting.

It was brought out in connection with this paper that a committee of prominent English metallurgists are investigating this subject of nitrogen in steel thoroughly, to decide between the conflicting reports, and they should have their final opinion published soon.

Removal by Titanium or Vanadium

Another interesting reference to nitrogen in steel is an abstract of an article by Tschischewski and Blinow in *Revue de Metallurgie* (Extraits, 1915, vol. 12, p. 473). It was found by these investigators that neither 33.5 per cent ferrovanadium nor metallic titanium 83.2 per cent pure removed nitrogen from iron, but formed soluble nitrides, thus sometimes even increasing the nitrogen content, especially in the presence of manganese and silicon. They advised a shortening of the melting period of titanium or vanadium steels to prevent the absorption of too much nitrogen.

Their conclusions, however, are directly at variance with results obtained by the Titanium Alloy Manufacturing Co. on nitrogen in titanium-treated and untreated rail steels A dozen pairs of open-hearth steel rails were investigated for nitrogen in the company's laboratory; each sample representing a different heat, but each titanium-treated sample coming from the same rolling as the corresponding untreated sample. Practically all these samples were "A" rails, or from the tops of ingots, and the treated steels received 0.1 per cent metallic titanium in the form of ferro-carbon-titanium alloy in the ladle. They were analyzed according to the method described by L. E. Barton in the *Journal of Industrial and Engineering Chemistry*, vol. 6, p. 1,012 ("Improved Method for the Determination of Nitrogen in Steel"), and the writer is also indebted to Mr. Barton for the results tabulated in Table I and obtained under his personal supervision.

TABLE I. NITROGEN CONTENTS OF OPEN-HEARTH RAILS

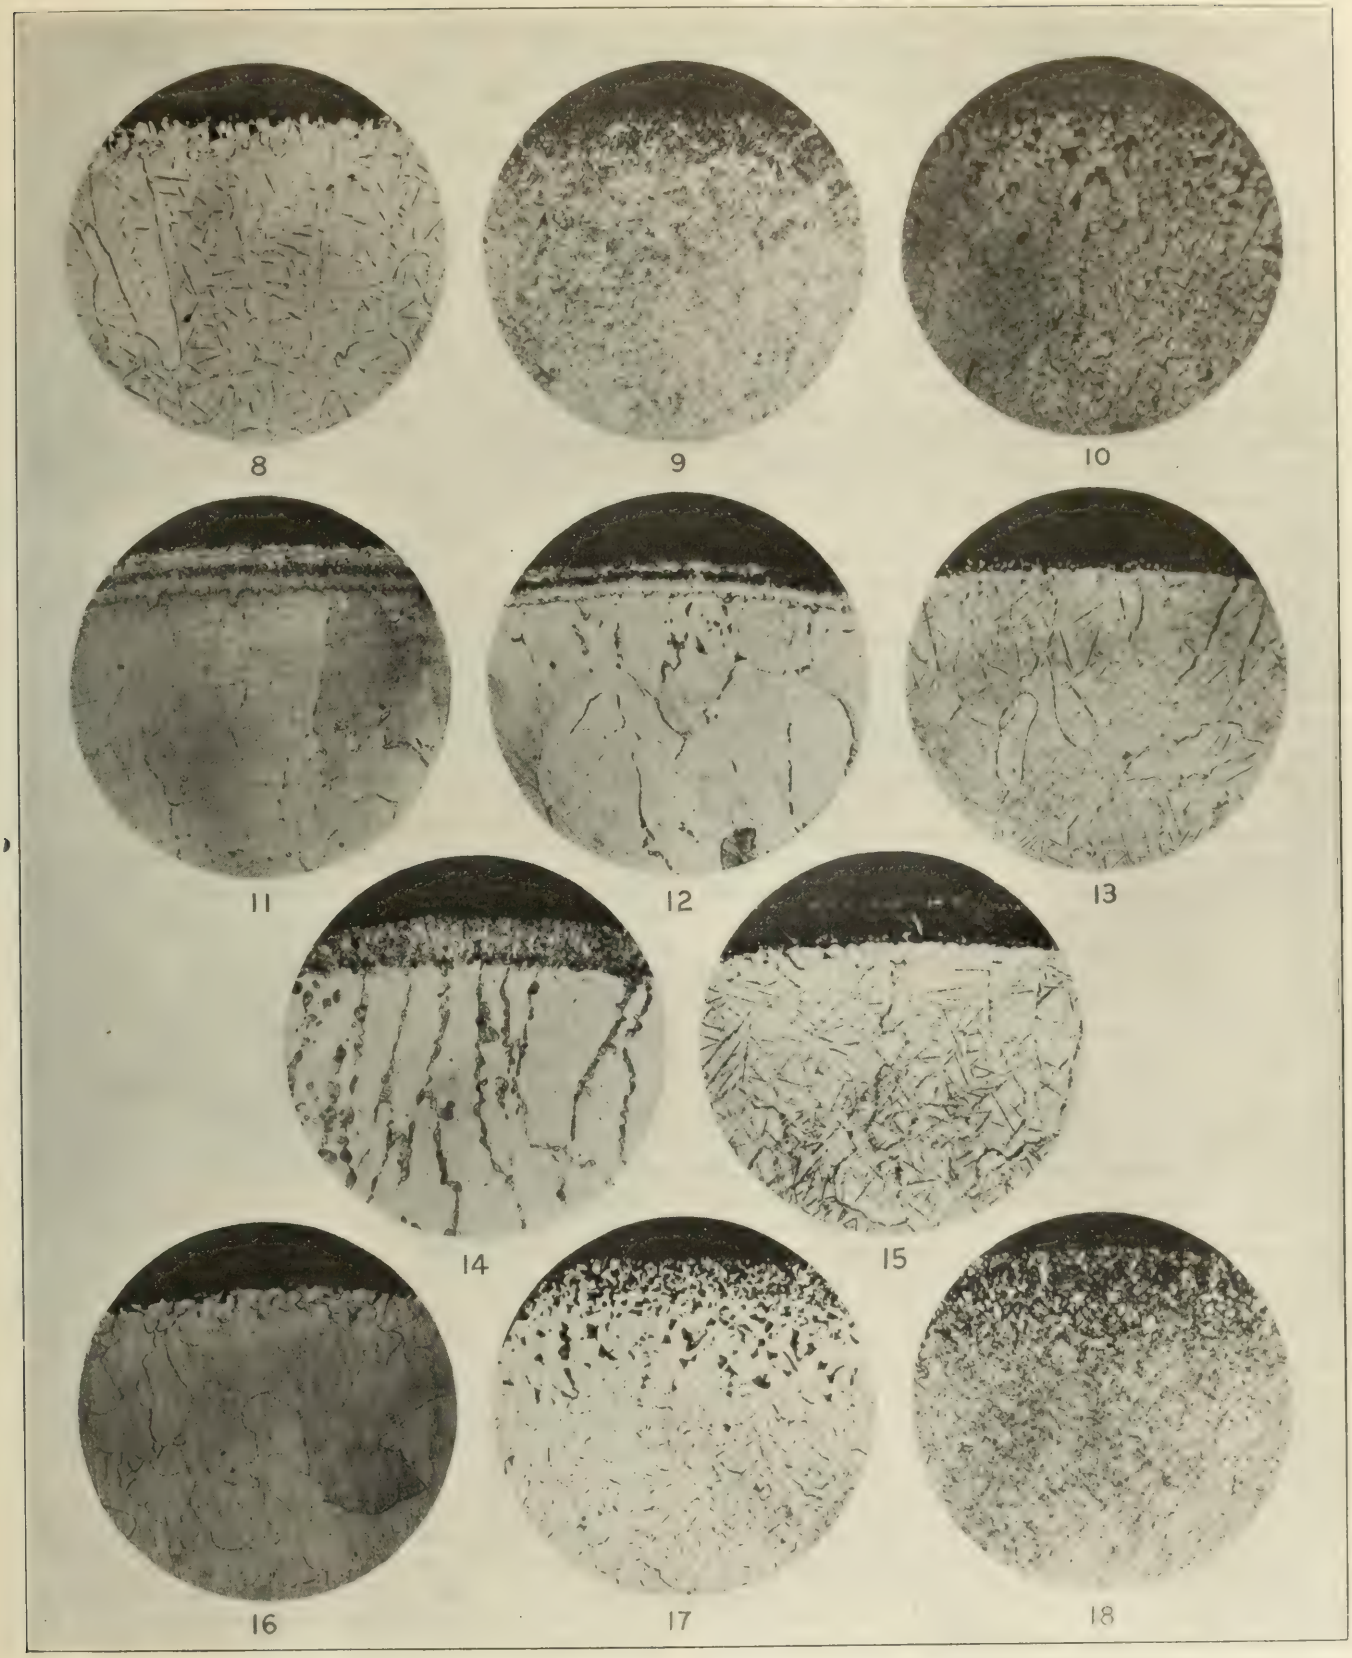
Mill	Rolling	Untreated Samples	Titanium-treated Samples
A	1	0.0038	0.0027
A	2	0.0054	0.0035
A	3	0.0047	0.0044
		0.0039	0.0035
		0.0034	0.0031
A	4	0.0040	0.0032
A	5	0.0048	0.0038
		0.0040	0.0034
B	1	0.0056	0.0034
B	2	0.0059	0.0029
B	3	0.0046	0.0046
B	4	0.0048	0.0040
Average		0.0046	0.0035

These figures show a quite consistent decrease in nitrogen content in the titanium-treated steels, and indicate without much doubt that titanium has an influence on nitrogen in steel. In bessemer and electric steel considerably more nitrogen has been found, the results usually being around 0.02 per cent. This agrees with the conclusions of most other investigators, that in the bessemer process where air is blown through the steel, or in the reducing conditions of the electric furnace, more nitrogen is absorbed than in the oxidizing open hearth, where the slag intervenes between the air and metal.

On Nov. 12, 1918, the Faraday Society held a general discussion on occlusion of gases by metals, and this subject was covered thoroughly by several authorities. Most of the discussion was, however, along the lines of the contamination of metals by all gases in general, and the effects and prevention of the resulting unsoundness. Sir Robert Hadfield in the introductory remarks of this symposium reviewed some of the previous important work on the subject, and gave a bibliography including the work on nitrogen in steel, as well as on the general subject of the occlusion of gases.

Nitrogen in Fusion Welds

The recent increase in interest in the art of fusion welding of steel by the arc or oxy-acetylene processes, on account of their use in place of riveting in ship construction, has caused attention to be drawn to the absorption of nitrogen during this operation. One of the earliest articles dealing with this phase of the nitrogen question was that by B. Strauss mentioned above, which appeared first in *Stahl und Eisen*, and was abstracted later in the *Iron Age* (1916, vol. 97, p. 432). Another was written by S. W. Miller, entitled "Some Structures in Steel Fusion Welds" which appeared in the *Transactions* (1918, vol. 58, p. 700), American Institute of Mining Engineers. Miller gave numerous illustrations and careful descriptions of the needles and other structures due to nitrogen occurring in iron deposited in his welds, but he then considered that the constituent producing these structures was cementite. Later he admitted that the needles, etc., were probably due to nitrogen, and in another paper, "Path of Rupture in Steel Fusion Welds" (*Bulletin*, American Institute of Mining Engineers, No. 146, Feb., 1919, p. 311), he gave another interesting series of illustrations of these structures. He reached the conclusion here that the brittleness of steel fusion welds was primarily due not to the needles or other forms of occurrence of nitrogen, but to extremely thin intercrystalline films presumably of oxide.



Heat Treatment of Nitrogenized Iron

All × 50

The microstructure of a fusion weld containing nitrogen, both as made and after heat-treatment, was described in a paper by G. F. Comstock entitled "Microstructure of Iron Deposited by Electric Arc Welding" in the January, 1919, *Bulletin*, American Institute of Mining Engineers (No. 145, p. 43). It was found that the nitride was not easily removed from the steel by heating in air, and that there is no simple metallographic method for distinguishing between iron nitride and carbide (cementite) in steel. A more comprehensive description of the structures of nitrogenized iron and iron deposited by the electric arc was given in an article by W. E. Ruder, "The Metallurgy of the Arc Weld," published in the December, 1918, number of *General Electric Review* (vol. 21, p. 941). Nitrogen is here stated to occur in iron in the form of lines or plates, or as dark eutectoid patches not unlike pearlite, or as a cement between the grains. In carbon steels there may be no metallographic evidence of nitrogen, although 0.15 per cent may actually be present. As little as 0.06 per cent nitrogen will reduce the elongation of a 0.20 per cent carbon steel from 28 per cent to 5 per cent. In regular steel it is present in only very small amounts (0.02 per cent in bessemer to 0.005 per cent in open-hearth), but under the conditions of arc welding it seems to become much more active, and combines either directly with the iron vapor or indirectly by means of nitrogen-oxygen compounds. Ruder states that both nitrides and oxides must be removed before such a weld can be ductile, but no scavenging agent has yet been found which will retain any efficacy after passing through the arc. Various experiments are described by Ruder which resulted in proving that the lines or needles found in welds are certainly due to nitrogen.

Microscopy

Some photomicrographs are included in this article to illustrate some of the structures produced by nitrogen in steel. Fig. 1 shows some iron specially nitrogenized in the General Electric Co.'s laboratory, illustrating two forms of occurrence, needles and pearlitic masses. This specimen was etched with boiling alkaline sodium picrate to darken the nitride, and was photographed at a magnification of 400 diameters. Fig. 2 shows one of the pearlitic masses in the same specimen magnified three times as much. Figs. 3 and 4 show two modes of occurrence of nitrogen in an electric arc weld, both taken at a magnification of 400 diameters after etching with nitric acid. The former shows the weld as made, cooled very rapidly by the cold steel plate that was welded; the latter is a slightly annealed specimen cooled more slowly. Fig. 5 shows some needles or small particles of nitride found in bessemer blown metal cast without deoxidation or recarburization. The sample was of course very porous, and full of oxide globules. This was etched with picric acid and magnified 400 diameters. Figs. 6 and 7 show typical crystals of titanium nitride in steel, both unetched, the former in a titanium-treated 0.50 per cent carbon electric steel, magnified 200 diameters, and the latter in an arc weld made with a hollow electrode filled with pulverized metallic titanium, magnified 400 diameters. These titanium nitride crystals are very hard and angular, and are orange-pink in medium- or high-carbon steel, and yellow when the carbon is low. They are thus easily recognized with the microscope by their color and form.

From this outline of the present knowledge regarding nitrogen in steel, it appears that many of the theoretical aspects are still to be worked out. The structures, for instance, have not been thoroughly explained, nor the compounds, solubilities and other properties definitely settled. Neither is it clear why the structures change on heat-treatment as they do, since the alloys lack critical points.

The embrittling effect of nitrogen on steel has been definitely established beyond question, but no practical cure for this condition in fusion welds has been proposed so far. In ordinary commercial steel there is yet considerable doubt and difference of opinion as to just what practical importance attaches to the very minute amounts of nitrogen that can be found. Considering all the evidence available, it does not seem proved that the amounts of nitrogen present in commercial steel, except in circumstances so extraordinary as to be negligible in the long run, are of any particular detriment to the quality. There are also differences of opinion in regard to the removal of nitrogen from steel by titanium treatment when melted. Unquestionably, however, a nitride of titanium is formed, and a majority of the evidence supports the view that this nitride tends to separate and rise from the steel. The idiomorphic character of the crystals shows that they are insoluble in the liquid steel. At any rate when present in the form of these crystals, the nitrogen could not have the same embrittling effect as it might have when dissolved as iron nitride in the ferrite. G. F. C.

Recent Experiments on Nitrogenized Iron

Having noted the variety of opinions expressed by previous writers as to the metallographic appearance of nitrogenized iron and the effect of annealing upon the structure of fusion arc welds (see Figs. 3 and 4, also Ruder, *General Electric Review*, vol. 21, p. 941), the following experiments were undertaken to determine the effect of heat treatment, particularly the rate of cooling, upon the microstructure of nitrogenized pure iron.

A ¼-in. swaged bar of pure vacuum-fused electrolytic iron was nitrogenized by heating to 700 deg. C. for about 3 hr. in a stream of pure NH_3. It was then cut up into five parts, each of which had a structure as shown in Fig. 8.

Piece 1 was then heated to 600 deg. C. for 15 min. and quenched in water (Fig. 9). After examination it was again heated to 600 deg. C. for 15 min. and allowed to cool with the furnace (Fig. 10). The micrographs show that this short heating to 600 deg. was sufficient to cause absorption of the needles by the ferrite and in the quenched sample the nitride needles are largely held in solution. Upon slow cooling from this temperature the nitride does not re-appear as needles but as pearlitic patches (as in Fig. 2) and intergranular material.

Sample 2 was then heated to 700 deg. C. for 15 min. and quenched in water (Figs. 11 and 12), following which it was reheated to 700 deg. C. for 15 min. and slowly cooled. Quenched from this temperature the grains are much larger than when quenched from 600 deg. C. and the only appearance of the presence of nitrogen is at the grain boundaries, which widen and become more distinct upon deeper etching. On slowly cooling the reheated sample, however (Fig. 13), the needles again make their appearance. Apparently a temperature of at least 700 deg. C. with slow cooling is required to show any needles. In this case the nitrogen appears both as needles and widened grain boundaries.

Sample 3 was treated the same as the previous ones, except that in this case the temperature was 800 deg. C.

The results were about the same as when treated at 700 deg. C., except that the grain boundaries are wider and not quite so dark (Fig. 14). On slow cooling the needles reappear as before (Fig. 15). Subsequent reheating and quenching brought back the structure shown in Fig. 14.

Sample 4 was treated in the same manner except that the temperature was 950 deg. C. At this temperature practically all the nitride is absorbed in the ferrite and is retained in solution by quenching, so that the micrographic appearance is practically that of pure ferrite. On slow cooling, the grain is much smaller and the nitride appears as needles and at the grain boundaries. Considerable diffusion of the outside nitride band inward has also taken place. This is significant in view of Strauss' contention that the dark pearlitic areas are due to the presence of carbon introduced by impurities in the ammonia. Inasmuch as these particles do not occur in the original bar as nitrogenized (Fig. 8), but do occur and disappear with heat treatment, it would seem that carbon had nothing to do with their occurrence.

Fig. 18 shows the appearance of the bar when heated to 1,000 deg. C. and slowly cooled. Both needles and widened grain boundaries are shown. Decided grain refinement with rapid diffusion inward of the outside nitride band is also evident.

Conclusions

In view of these results it seems evident that nitrogen may occur in a variety of forms, depending upon the rate of cooling and the degree of heat applied. The needles now commonly accepted as indicating the presence of nitrogen may not be visible at all, even in highly nitrogenized steel. The same is true of the widened grain boundaries. The presence of carbon does not seem to be necessary to the formation of the dark pearlitic-appearing patches. They are rather a function of the percentage of nitrogen present and the rate of cooling.

To call these needles Neumann lines or slip bands caused by cutting for polishing is erroneous, for if they were the former they should disappear on heating above Ac_3, which they do not, and if the latter, they should appear in the quenched as well as in the slowly cooled samples. These lines appear rather to be a nitride of iron which is entirely soluble at temperatures above 700 deg. C. in ferrite and retained in solution by quenching but rejected at the boundaries and cleavage planes on slow cooling.

Experiments described in a previous paper (*General Electric Review*, vol. 21, p. 941) show that nitrogen in steel is quite stable and may be driven off only after prolonged heating at a high temperature *in vacuo*, or by passing hydrogen over the sample at about 600 to 700 deg. C.

Rubber Tires in China

It is reported that the rubber tire industry is getting to be so large in China that manufacturers are talking of starting their own factories in that country. While Peking has less than 1,000 automobiles, there will be many thousands of motor vehicles in operation in the near future.

The typical vehicle of today is the jinrikisha, and rubber tires are being employed. Every 24 hours 50,000 of these jinrikishas pass through the great central gateway of Peking.

Problems Investigated at the Color Laboratory, Bureau of Chemistry

By H. D. Gibbs

THE Color Laboratory of the Bureau of Chemistry was organized early in 1916, for the purpose of studying colors, their formation and uses. Shortly after its organization Congress appropriated $50,000 for the first year, and since that time two appropriations of $75,000 each for the second and third years, and for the fourth year, beginning last July, $100,000 has been secured to carry on the work, providing for personnel, building and equipment. The immediate object of the work has been to make detailed studies of reactions, processes and apparatus, with a view to assist the development of the American chemical industries, with special reference to the organic preparations that are necessary in the production of dyes and also to carry on studies in the natural agricultural products that have such great value in industry. It has been realized from the start and is being more and more appreciated by American industries that success depends upon the ability to produce compounds at a low cost. To do this the factor of yields is the most important, and detailed studies throwing light upon the mechanism or reactions have been undertaken. In many cases the long and tedious investigations necessary to work of this nature cannot be undertaken by industrial research laboratories where the press of factory problems is very great.

In order to carry on this work an old building at Arlington, Va., was taken over and remodeled so far as possible to suit the need. Various lines of research were started in the meantime in the laboratories of the Bureau of Chemistry. The plant at Arlington is unique in that it combines manufacturing facilities with complete laboratory equipment.

The technical part of the plant is being equipped with an extensive variety of large-scale apparatus. This is to be operated, not for the purpose of manufacturing, but for the purpose of studying manufacturing operations. It is quite possible that where the industries of the country are not able or willing to furnish compounds that are required we will be able to manufacture and supply the demand until the industries are in a position to undertake the work.

Photographic Sensitizing Dyes

One investigation has now arrived at this stage of development. I refer to the production of the photosensitizing dyes of the quinoline type. Of these pinaverdol, pinacyanol, or thochrome, dicyanine, and dicyanine A have been successfully synthesized and tested by physicists, astrophysicists and plate manufacturers. A number of plate manufacturers have been very successful in incorporating several of these dyes in photographic gelatine emulsions, and tests of the plates so produced show them very satisfactory and the dyes to be at least equal in performance to the corresponding dyes formerly produced by Meister Lucius and Brüning. The American patents on some of these dyes were formerly owned by the Höchst concern, but are now the property of the Chemical Foundation. The Color Laboratory is prepared to instruct chemists who will undertake the commercial manufacture of these dyes and assist in any way in stimulating the production of

these valuable aids to the physicist and photographic plate manufacturer.

With the exception of the photographic sensitizing dyes, the investigations so far undertaken have been quite general in character and include vapor phase studies in chlorination, oxidation and sulphonation, a study of caustic fusions, a study of the derivatives of cymene, at present a waste product of the sulphite spruce paper industry, and there is also under way in the laboratory at this time a study of the vapor pressure curves of a number of aromatic organic compounds.

Thirty-one papers have been written by the laboratory staff, more than twenty of which have already appeared in print, and many others are in course of preparation. Owing to the demands of the industries for chemists and the interference of the war, the personnel of the Color Laboratory has undergone many changes, in fact almost completely changed twice, and our plant has been greatly delayed in construction. For these reasons it has been very difficult to carry research to a conclusion.

FIG. 1. ELECTRIC TRANSMISSION LINE, 6,600 VOLTS. A VIEW OF NORTH AND WEST SIDES

I will describe very briefly a few of the investigations that so far have not been published.

Vapor Phase Chlorination

The chlorination of toluene in the vapor phase, catalyzed by ultra violet light, for the production of benzyl chloride, benzal chloride and benzotrichloride, has been studied. The work to the present has indicated that the extent of the chlorination can be controlled to a considerable extent by the character of the light, the relation between the reacting gases and the temperature. Low-pressure quartz mercury lamps tend to produce mostly benzal chloride, while high-pressure lamps produce more benzotrichloride. G. A. Geiger, A. B. Clark and H. A. Lubs have published some preliminary analytical papers on this work.

Vapor Phase Oxidation and Vapor Phase Sulphonation

Studies of the vapor phase oxidation of various hydrocarbons and other compounds by means of atmospheric air in the presence of catalysts have shown that toluene can be oxidized to benzaldehyde and benzoic acid, naphthalene to phthalic anhydride and benzoic acid, anthracene to anthraquinone, phenanthrene to phenanthraquinone. Preliminary publications are being prepared by C. Conover, K. P. Monroe and myself.

A number of methods are in practical application for the sulphonation of various compounds. The most common consists in the mixing of sulphuric acid of suitable strength and the compounds to be sulphonated in an iron pot, stirring the mixture rapidly with or without the application of external heat; the Tyrer process,[1] consisting in the passing of the vapors of the substance to be sulphonated through sulphuric acid heated to the desired temperature; the Downs method,[2] consisting in heating the substance being sulphonated and the sulphuric acid *in vacuo* for the purpose of removing the water and sulphuric acid by distillation; and the Kendall process,[3] providing for the addition of the compound to be sulphonated to the molten liquid form of certain acid sulphates or pyrosulphates. All of these are batch processes. The first continuous process is that devised by Dennis[4] and perfected by Bull,[5] which has been used for the production of the monosulphonic acid of benzene. It consists in pumping benzene through sulphuric acid and then into water, producing a continuous circulation of the benzene, and the process depends upon the fact that small quantities of benzene monosulphonic acid are dissolved in the benzene and carried to the water, where it is washed out and the benzene re-circulated through the sulphuric acid. Our process differs materially from any of the above in that it is continuous, the products of the reaction are removed very rapidly, as formed, and in that various compounds can be sulphonated successfully at any required temperature.

The sulphonation of various hydrocarbons in the vapor phase with sulphuric acid of varying strengths has been successfully carried out by this process on a small scale.

Benzene can be sulphonated with chamber acid (55 deg. Bé. = 70 per cent). Naphthalene can be made to yield a product containing disulphonic acids of which the 2.7-derivative constitutes about 85 per cent, while the 2.6-derivative makes up the remainder of about 15 per cent. The former furnishes a valuable starting material for the much used H acid. J. A. Ambler, C. E. Senseman and William J. Cotton are preparing preliminary papers on this work.

War Work

During the war the incompleted building at Arlington was loaned to the Nitrate Division of the Ordnance, and the laboratories and almost the entire personnel of the Color Laboratory were engaged in work for the Chemical Department of the Science and Research Division of the Bureau of Aircraft Production. Some of the chemical problems solved for the Air Service were rather interesting, and I will outline a few of them.

Early in the prosecution of the airplane program it became evident that new sources of acetic acid and its derivatives must be developed, since the manufacture of smokeless powder promised to require all of the acetone production in sight. Two entirely new processes employing raw materials not heretofore used for any purpose were developed, the first to produce acetic acid, the second to produce acetone.

Hudson, Harding and La Forge, of the Bureau of Chemistry, very recently devised a method for the

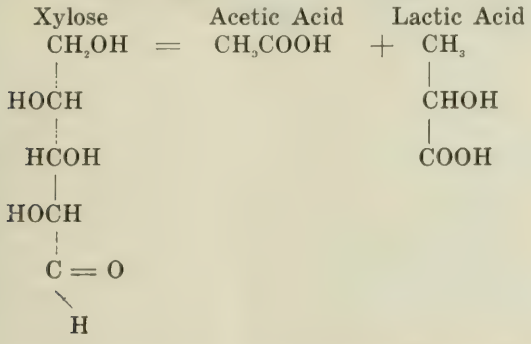
manufacture of xylose on a commercial basis at a very low cost, from such abundant materials as corncobs and wood, and L. A. Round, also of the Bureau of Chemistry, had isolated an organism that would ferment xylose, with the production of acetic acid. It seemed very desirable that this process should be investigated to determine if it were practicable for commercial application. Substances rich in xylane, such as corn silage, sauerkraut and manure, seemed most likely to contain xylose-fermenting bacteria. It was found that pure cultures could be obtained by fishing from plates and seeding into liquid 2 per cent xylose yeast medium. The fermentation process was found to proceed very nearly quantitatively as represented by the splitting of one molecule of xylose into one molecule of acetic acid and one molecule of lactic acid, according to the equation:



It has been found that the oxygen supply within wide limits has little effect. The process has been successfully carried out on a small scale by grinding corncobs, hydrolyzing and inoculating the solution so formed, thus reducing the expense of the process in that it is not necessary first to isolate the xylose. An article descriptive of this work, by Fred, Peterson and Davenport, appeared in the September issue of the *Journal of Biological Chemistry.*

Isopropyl Alcohol and Acetone

It has been found that the waste gases of the Burton process for cracking petroleum can be used for the production of isopropyl alcohol and acetone. These gases contain from 8 to 14 per cent of propylene, which can be absorbed in sulphuric acid of the proper strength. This solution, on hydrolysis, gives isopropyl alcohol, and a continuous catalytic process has been devised for converting isopropyl alcohol into acetone. This consists in passing the vapors of isopropyl alcohol, mixed with atmospheric air, over a catalyst and thus removing two hydrogen atoms from the isopropyl alcohol, the result being acetone. It has been estimated that from 50,000 to 100,000 gal. of acetone can be produced daily by this process if all of the waste gases from the Burton stills were utilized. A paper, by R. R. Williams and myself, descriptive of this work will appear shortly.

FIG. 2. AN AIRPLANE VIEW OF A PLANE IN PROCESS OF PRODUCING ARTIFICIAL CLOUD

The Discharge of Clouds From Airplanes

A number of uses for clouds discharged from airplanes were suggested, and the following three that were investigated by R. R. Williams are interesting, only two, however, being of real value:

It was found that signals could be discharged from airplanes in a very satisfactory manner by a series of colored clouds in the form of smoke balls or streamers released at irregular intervals, somewhat in the manner of Morse or Continental codes. For this purpose a solution of volatile dye in a volatile solvent may be discharged into the engine exhaust. The result is a smoke colored according to the dye used. A saturated chloroform solution of Sudan II[6] gave very satisfactory results. The smoke was cherry red and very clearly visible at an altitude of 5,000 ft. Observers state that they believe it would have been visible at 10,000 ft.

Another possible use for smoke on airplanes is the imitation of a plane in flames. This was fairly satisfactorily demonstrated by spilling 15 lb. of lampblack at a uniform rate from a position near the observer's seat on a plane that was in the meantime maneuvering to imitate loss of control.

Several men connected with the force at Langley Field, who saw this test in operation, without knowledge of its object, were deceived by it and shouted to call attention to the machine on fire.

School of Optics

There has been established at Paris an optical institute that will work in the interest of the manufacturers of opticians' supplies, according to *Science;* it will not be conducted for commercial profit, but solely for the purpose of advancing optical science and the optical industries for the common welfare. The forms of activity of this new scientific institute will be: (1) a training school of optics; (2) a laboratory of research and experiment, and (3) a professional school for advanced study. The school of optics will train experts in the manufacture of optical goods. C. Fabry, at present professor of general physics at the Faculté des sciences de Marseilles, has been selected as the head of the new institution. Lucien Poincaré, rector of the University of Paris, has evinced an especial interest in the institute and has expressed his intention of requesting a professional chair of optics at the Sorbonne. The laboratories will comprise a research department in which the instructors of the school may conduct their theoretical and practical researches with relation to the various kinds of glass, optical instruments and opticians' accessories, and a department for the study of manufactured products or any matter of importance submitted for examination by the institute. These laboratories will serve likewise for the training of students.

Pumping Acid With Compressed Air

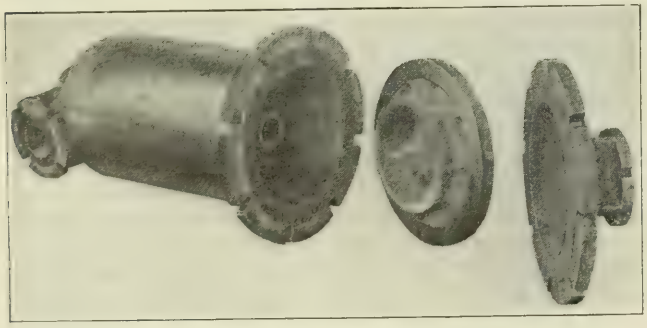
By John Oliphant
Chief Engineer, Pumping Dept., Sullivan Machinery Co.

During the past two or three years, the use of compressed air for handling, elevating and transferring acids and chemical solutions has been greatly extended, and as the more modern principles of air-lift pumping have been applied to the chemical field, the efficiency and convenience of the system have made rapid strides. The advantages of the air-lift system for handling acid as compared with mechanical pumps or other less modern mehods and as demonstrated by actual installations made by the company with which the writer is associated may be enumerated briefly as follows:

Durability—The foot pieces and separator heads may be made of any desired acid-resisting material, such as hard or soft lead, rubber, cast iron or cast steel, "Duriron," etc. There are no moving parts to cause wear, and the free open passage characteristic of this apparatus secures a much longer life than that enjoyed by mechanical pumps.

Flexibility—The normal delivery may be increased as much as 25 per cent or decreased by the same amount with very little change in operating efficiency. Still greater variation may be obtained, although with a sacrifice in efficiency. This is accomplished by the movement of a valve controlling the air supply.

Principles of the Air Lift—The principle of the air lift is to lighten the column of water in the eduction pipe with air so that the weight per sq.in. of the eduction column mixed with air at the air jet is less than the submergence head. For a low percentage of submergence, more air must be used than with a high percentage of submergence for the same lift in order to keep the weight of the eduction column below the submergence head. However, with the low submergence, a lower pressure is required, so that the power is theoretically equal. The question of velocity and air expansion, in a low lift with a low submergence, is one that requires especially careful designing. With acids, however, the high specific gravity and high temperature of



SEPARATOR HEAD

the liquids to be handled give better results with low percentage of submergence than is secured with water.

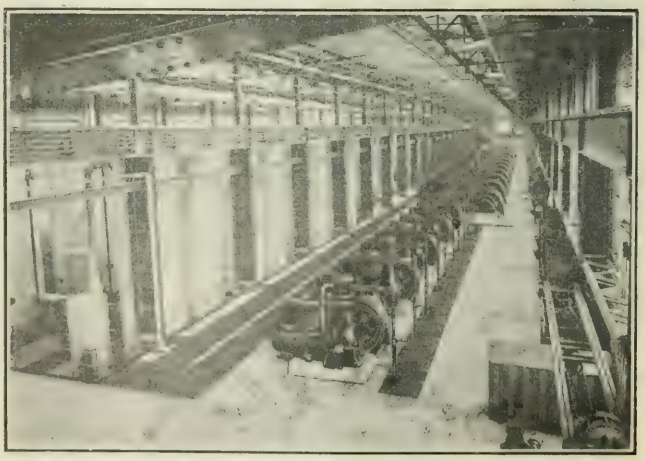
Submergence—Submergence is a term used to indicate a head into the intake of an air lift pump and controls the pressure at which the pump operates. It is expressed in feet to the point above the foot piece to which the liquid would rise in the eduction pipe without the aid of the air. The submergence added to the lift is called 100 per cent and the percentage of submergence is always a complement of the percentage of lift. For instance, 60 per cent submergence would always mean 40 per cent lift, 35 per cent submergence 65 per cent lift. The percentage of submergence may vary with the lift. In pumping water a higher per cent of submergence is desirable for low lift and the percentage of submergence may be decreased as the lift increases up to certain points. The air-lift is usually thought of as suitable only for deep wells, but with improved apparatus and careful engineering, excellent results in overall efficiency are being shown on relatively low submergences. In cases not permitting wells or

ACID FOOT PIECE AND MIXING TUBE

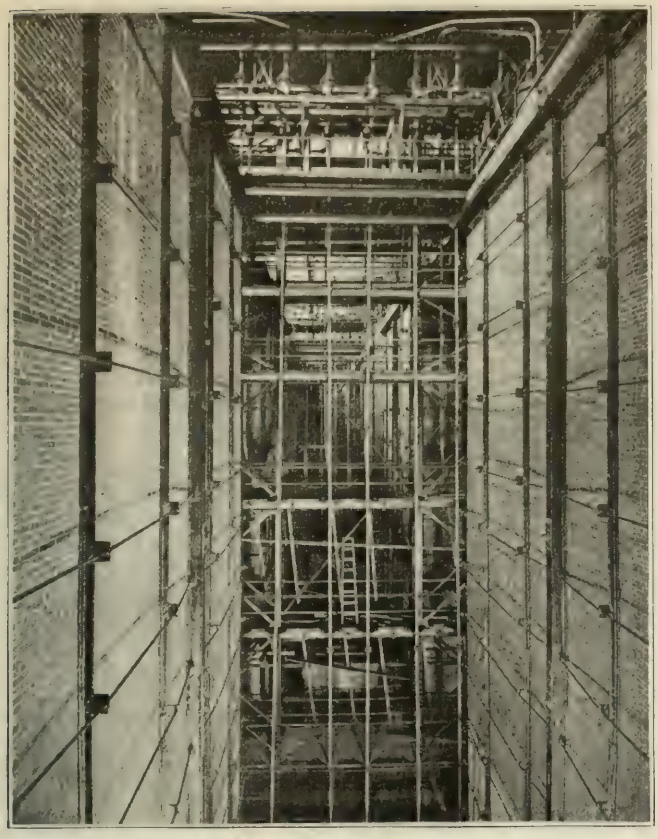
holes to be drilled to secure the necessary submergence, the compound lift may be employed. This involves lifting the acid or other fluids to a sufficient elevation to give adequate submergence for the final lift.

Central Power Supply—The air-lift foot pieces or jets may be located at any desired point in the plant and operated by air from a central station with little loss in friction and no loss such as that of condensation or drop in power as is experienced with steam or electric transmission. The compressor is under the eye of the operating engineer, and attendance of mechanics at the point of use is unnecessary, as would be the case for repair or adjustment of mechanical pumps. The towermen readily control the volume pumped from each unit as well as the starting or stopping of it by means of air valves.

Efficiency—The equipment and system employed by this company in its air-lift apparatus secure the thorough mixing of the air and the fluid to be raised by means of a large number of fine jets of air, discharging into a thin sheet of the fluid. With this equipment and with careful installation, the pump efficiency averages from 30 to 35 per cent. While this may be exceeded by mechanical pumps under test conditions, it is found, under actual practice, that the air-lift is more efficient and maintains its efficiency at a higher point, after a short period of operation. This is on account of the



SERVICE COMPRESSORS, LIQUID AIR BUILDING PLANT NO. 2



ACID LIFTS AND SEPARATING HEADS IN ABSORPTION BUILDING, PLANT NO. 2

detrimental effect of the acid on mechanically operated pumps of either the centrifugal or plunger type; while at the same time the cost of repairs and attendance is eliminated.

Safety—The separator head furnished by this company performs another service, namely, that of conveying away the fumes or air integrated with the acid, so that the employees are not exposed to this dangerous element. The fumes can thus be carried into the tower or to any other point desired.

Design—A word of caution may be in order in reference to air-lift installations. While as described above, when proper equipment is selected and the installation made by experienced engineers, the results are superior to those obtained by other means, seemingly unimportant differences in pipe areas and in the handling of the air many times make a considerable difference in the effectiveness of the installation.

Nitrate Plant No. 1

An example of this compound lift is found at the United States Nitrate Plant No. 1, Sheffield, Ala. The problem consisted in raising the acids through a tank 60 ft. above the surface from a sump or selecting pit 20 ft. in depth. Two rows of Sullivan Compound Jets and Pumps were installed on either side of a steel tower containing the tank. The acid was delivered at a point a foot or two above the surface and the drop into the pit gave a submergence of 20 ft. Using a submergence of 50 per cent, a discharge was obtained at a point 20 ft. above the surface. The air and acid were separated in a separator tank at that point, the acid being then carried back to the second foot piece, at which a submergence of 40 ft. was obtained for the second lift. Figuring the submergence at 50 per cent, the acid was carried readily to the final elevation 60 ft. above the surface.

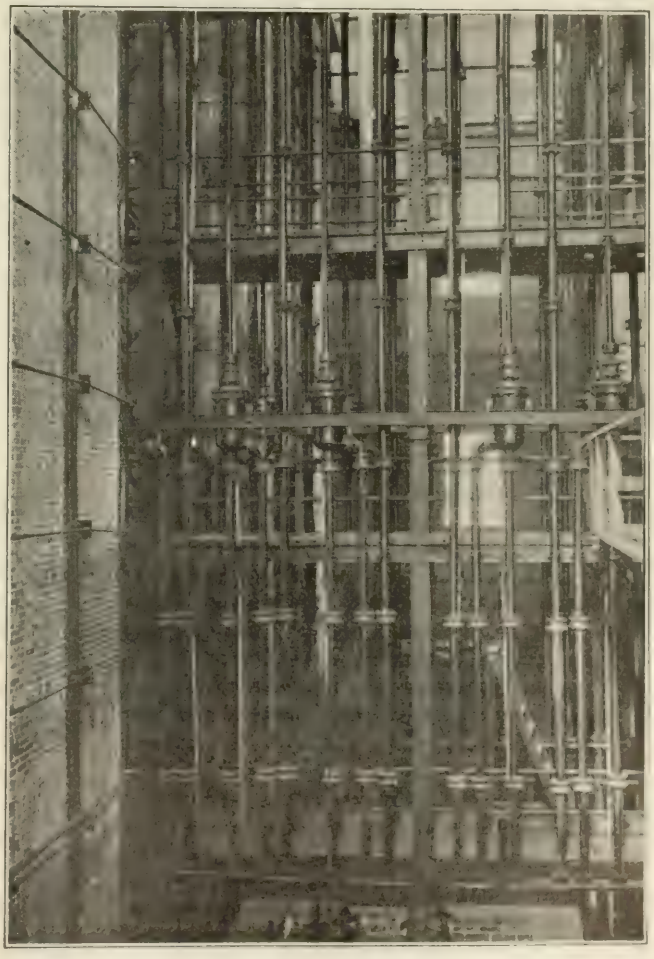
While this arrangement requires more air than a single lift, a lower pressure is sufficient. The actual power needed is no greater than that necessary for a single lift of 60 ft. with 50 per cent submergence.

Compressed air at 40 lb. pressure for the lifts described above is supplied from the central power house, where two Sullivan Corliss Tandem Compound Duplex Air Compressors, type WC, are situated. These compressors supply 1,500 cu.ft. of free air per min. each.

The purpose of handling the liquid at both No. 1 and No. 2 plants, the latter to be described later, was to convert water into nitric acid by bringing it in contact with a nitrous gas. At one end of the absorption tower building the solution was practically water, viz., a 5 per cent solution, and was pumped up into the tank at the top of the absorption tower building, where it absorbed a certain amount of acid from the gas with which it came in contact and was then discharged into the next well and thus pumped back and forth, until after passing through several stages (six in Plant No. 1) it left the building at 50 per cent strength.

Nitrate Plant No. 2

The problem in Nitrate Plant No. 2 was to lift approximately 50 gal. of acid per min. with each lift from the bottom to the top of the tower. The actual lift to be performed was approximately 70 ft. As the tower bottom was only about 3 ft. above the ground level, 12-in. iron casings were sunk to a depth of 100 ft. in



AIR LIFT INSTALLATION AND ABSORPTION TOWERS, PLANT NO. 1. SEPARATOR HEADS IN CENTER

AIR-END VIEW OF THE SIX TWIN ANGLE-COMPOUND COMPRESSORS, PLANT NO. 2

the ground below the building. Pipes 3 in. in diameter carried the acid from the foot of the tower to the top of the wells, and then down to the Sullivan foot pieces at the bottom of the wells. At this point air was introduced and the air-lift took effect through a 3-in. eduction pipe, lifting the acid to the top of the tower. These pipes were made principally of aluminum and Duriron and the nitric acid, as stated above, varied from 5 to 50 per cent strength. There were 120 of these wells sunk, some on each side of the steel towers.

At the top of the tower the air was separated from the acid by use of a simple separating head designed by the Sullivan Machinery Co. and made of Duriron. The acid was drained out over and into the tower through distributors, and the air which had been used in lifting the acid was carried out of the building through main headers, so that the fumes would not injure the workmen. By this method relatively low pressure could be used and perfect regulation of the pumping was secured. The diameter of the air supply pipes leading to the bottom of the well was 1¼ in. and these were made of aluminum. Air valves as well as the valves on the acid pipe line were used for regulating the flow of the acid and for the starting and stopping of each individual lift. The type of nozzle or foot-piece used on both Plant No. 2 and No. 1 is illustrated in the accompanying photograph. The air was mixed with the acid by a large number of jets which discharged into a sheet of the acid, securing an almost perfect emulsion.

Air Installation, Plant No. 2

Compressed air at 100 lb. pressure for the acid lift at No. 2 plant was supplied by six WN-4 Twin-Angle Compound Compressors with a capacity of 2,600 cu.ft. per min. This plant is shown in the accompanying illustration.

These compressors are equipped with plate valves of the end-rolling finger pattern and are operated by direct-connected electric motors mounted on the crank shaft of each compressor.

We are indebted to the officials of the Ordnance Department, U. S. Army, for the permission to use these photographs and data, which were supplied by the Chemical Construction Co., engineer and subcontractor for the chemical installations at Plants Nos. 1 and 2; to the Duriron Castings Co., of Dayton, Ohio, by whom the air lift pumps and separators, designed by Sullivan pneumatic pumping engineers, were made up, and to the American Cyanamid Corporation.

New Ceramic Research Station at Rutgers College

By E. C. Millen

WITH the ratification of a bill by the New Jersey State Senate, Feb. 2, covering an appropriation of $100,000 for the erection of a new ceramic building at Rutgers College, New Brunswick, there is every indication that this measure will be approved by the State Assembly, receive the Governor's signature and so become a law. This fund will give New Jersey what it has long needed—a first-class ceramic institution for instruction and research work.

The movement for this new building has been under way for the past few months, receiving the united support of those prominent in the clay-working and affiliated industries throughout the state. The bill referred to provides for the construction of a building, together with the proper machinery, apparatus and equipment, at an expense of 100,000, to be paid by the state, and an additional appropriation of $12,000 annually, beginning in 1921, for salaries, supplies, etc.

Ceramic Industries in New Jersey

In bringing forward proof of the necessity for this new building, it is pointed out that in the ceramic industries New Jersey is second in importance of all the states, being exceeded only by the State of Ohio. The clay deposits of the state are the most important on the Atlantic seaboard, while the local plastic clay resources rank first among those of the entire country—for firebrick and refractory manufacture they are unsurpassed. There are about 18,000 persons engaged in the industry in New Jersey at the present time and in this connection, recent statistics compiled by the Bureau of Industrial Statistics, State Department of Labor, are of particular interest in showing the number of plants, capital invested and value of production. These, computed in 1918, are:

	Number of Plants	Capital Invested	Annual Value, Products
Brick and terra cotta	68	$24,495,287	$15,501,229
Potteries	56	13,577,633	12,948,702
Glass plants	42	10,057,375	11,021,834
Tile	11	1,274,147	1,261,150
Lime and cement	11	12,038,834	4,521,529
Clay mines	39	1,035,703	790,796
Total	227	$62,478,979	$46,045,240

To bring these figures up to date, it is estimated that the capital invested is over $65,000,000 at this time, and the annual value of production close to $50,000,000.

The present ceramic building at Rutgers College is small in comparison with the three other recognized schools of this character in the country, which are at the Ohio State University, University of Illinois and Alfred University.

Plans for Research

At the new building in New Jersey, it is proposed to have broad facilities for research work in the solution of everyday problems arising in the industry, assisting state manufacturers in all phases of the industry in their work. It is estimated that this department will be self-supporting in a short time. The departments for instruction will be of modern and efficient status, providing everything necessary in this line. The work, as heretofore, will be under the direction of Prof. George H. Brown.

Theoretical Study of Nitrogen Fixation by the Electric Arc—III

Chemical Dynamics of the Nitrogen-Oxygen Reactions at the Temperature of the Arc and During Cooling—Multiple Arcs With Intermediate Cooling—Speculation on Cooling of the Arc by Adiabatic Expansion and by Molecular Diffusion*

By CHARLES P. STEINMETZ

EXTREMELY rapid cooling of the gases from the arc stream thus appears essential to save the NO produced by the arc. This is usually done by mixing the arc gases with a mass of relatively cool air, that is, passing only a part of the air through the arc. Since, however, the thermal equilibrium concentration of NO in air is not very high even at arc temperatures and a part thereof is lost by dissociation, further reduction of concentration by the admixture of cold air results in a very low concentration, 1 to 1½ per cent. As the result thereof, a very extensive NO absorption system is required, so that it is claimed that most of the cost of both installation and operation is due to the absorption system.

This makes it of interest to investigate whether higher concentrations could be produced by passing the air successively through a number of arcs with intermediate cooling. That is, a part of the air passes through the arc and then mixes with the rest for rapid cooling to the temperature where NO has become relatively stable; then the gas mixture is cooled again, a part passed through the next arc and mixed with the rest for rapid cooling, etc.

By this procedure, the NO content of that part of the gas mixture coming from the arc which passes through the next arc is lost, and thus, with increasing number of successive arcs, the efficiency decreases while the concentration increases.

As an $n$fold increase of concentration would reduce the absorption plant to $\frac{1}{n}$ or less, it is a commercial question how far the sacrifice of efficiency would be justified by an increase of concentration.

Assuming that the part q of the air is passed through the arc, and then immediately mixed with the remaining part $(1 - q)$ of the air for effective cooling, the gas mixture then is cooled and the part q passed through the second arc, etc.

Let T_1 = temperature of the gas mixture before coming to the arc, and T_2 the temperature of the gas mixture after the part q has passed through the arc. Let T_a = temperature of the arc, T_o = initial air temperature and T_c = temperature of the cooling surfaces (water or steam pipes, etc.) and s = cooling coefficient.

Let a_o = residual NO concentration of the arc gases, that is, that part of the NO concentration produced by the arc which is not dissociated before cooling. Let a_1 and a_2 be the NO concentration of the gas mixture before and after passing through the arc. Therefore, of the gas mixture of temperature T_1, and concentration a_1, the part q passes through the arc, and there acquires temperature T_a and concentration a_o, then mixes with the rest $(1 - q)$ of the gas mixture and this mixture thereby acquires the temperature

$$T_2 = (1 - q)T_1 + qT_a = T_1 + q(T_a - T_1) \quad (65)$$

and the concentration

$$a_2 = (1 - q)a_1 + qa_o = a_1 + q(a_o - a_1) \quad (66)$$

Then the gas mixture, passing over the cooler of temperature T_c, cools to the temperature

$$T_1' = T_2 - s(T_2 - T_c) \quad (67)$$

and at this temperature passes to the next arc at a concentration:

$$a_1' = a_2$$

For the first arc, it is:

$$a_1 = o$$
$$T_1 = T_o$$

Thus, after passing through n successive arcs, the NO concentration is

$$a_n = qa_o + (1 - q)[qa_o + (1 - q)]$$
$$[qa_o + (1 - q)][\ldots + qa_o]$$
$$= qa_o[1 + (1 - q) + (1 - q)^2 + \ldots + (1 - q)^{n-1}]$$
$$a_n = a_o[1 - (1 - q)^n] \quad (68)$$

The temperature reaches constant final value where the cooling from T_1 to T_1' is the same as the increase by the arc from T_1 to T_2, and thus $T_1' = T_1$. Substituting this into (67) and (65) gives the two equations for T_1 and T_2, the temperature of the gas mixture before and after passing the arc:

$$T_1 = T_2 - s(T_2 - T_c)$$
$$T_2 = (1 - q)\ T_1 + qT_a$$

These give:

$$T_1 = \frac{q\ (1 - s)\ T_a + sT_c}{1 - (1 - q)\ (1 - s)} = \frac{q\ (1 - s)\ T_a + sT_c}{q + s - qs} \quad (69)$$

$$T_2 = \frac{qT_a + s\ (1 - q)\ T_c}{1 - (1 - q)\ (1 - s)} = \frac{qT_a + s\ (1 - q)\ T_c}{q + s - qs} \quad (70)$$

As one arc gives the concentration:

$$a = qa_o \quad (71)$$

n arcs, if they have the same joint efficiency, should give the concentration:

$$na = nqa_o \quad (72)$$

and as, by (68), they give the concentration

$$a_n = a_o[1 - (1 - q)^n]$$

the efficiency of n successive arcs, compared with that of a single arc, is

$$n = \frac{a_n}{na} = \frac{1 - (1 - q)^n}{nq} \quad (73)$$

but the concentration is increased from a to a_n, that is, by the ratio

$$\log_{10} = \frac{a_n}{a} = \frac{1 - (1 - q)^n}{q} \quad (74)$$

As an instance let the arc temperature be assumed as T_a = 3600 deg. abs., and the temperature of the cooler as T_c = 400 deg. abs. At 3600 deg. abs., the

*For Parts I and II see CHEM. & MET. ENG., vol. 22, Nos. 7 and 8, Feb. 18 and 25, 1920, pp. 299 and 353.

equilibrium concentration is 6.15 per cent, but assuming a rate of cooling, by admixture, of $b = 10^7$ deg. per sec., the residual concentration of the arc gases is reduced to $a_o = 3.75$ per cent.

Assuming a cooling coefficient $s = 0.5$, and assuming $T_2 = 1400$ deg. abs. as the highest temperature at which the dissociation is still negligible, we get by substituting into (6):

$$1400 = \frac{3600q + 200\,(1 - q)}{1 + 0.5\,(1 - q)} = \frac{400 + 6800q}{1 + q}$$

Thus:

$$q = \frac{1}{5.4} = 0.185$$

This gives by (69):

$$T_1 = 900 \text{ deg. abs.}$$

In Table IX are given, for 12 successive arcs, the temperature, T_1 and T_2, before and after passing through each arc; the NO concentration in per cent and relative, and the efficiency ratio n. As seen, after 4 to 5 arcs, the temperatures have practically reached their maximum values. The same are plotted in Fig. 9.

Table X gives the same quantities, with the air mixture constant q chosen so that not the final temperature, but the temperature after passing through 1, or through 2 or 3 arcs, has reached the chosen temperature limit $T_2 = 1400$. On Fig. 9 these values are plotted as circles, three-cornered and four-cornered stars, for the same nq.

The larger the number of successive arcs, n, the smaller can be the air quantity q which passes the arc,

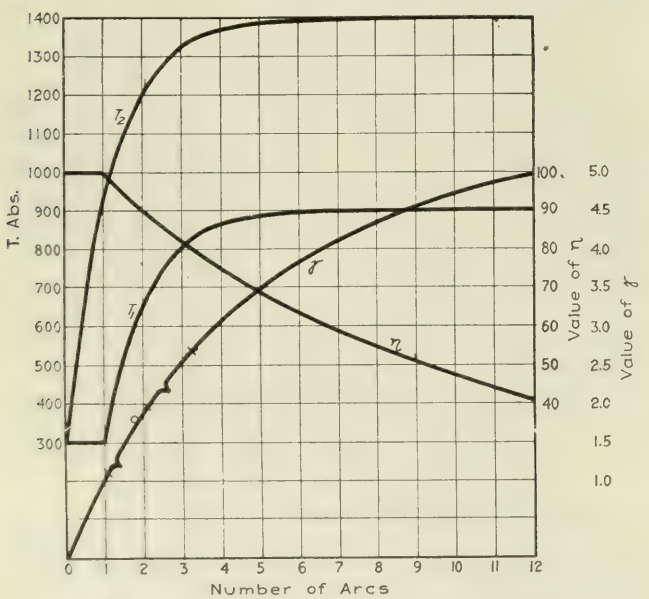


FIG. 9. MULTIPLE ARC NITRIFICATION

and the cooling coefficient s, to give the same concentration and efficiency. It is of interest then to consider the limiting values of a very large number of successive arcs, if acting upon a very small part of the air only, with very little intermediate cooling.

Substituting thus for n, q and s the values pn, $\frac{q}{p}$ and $\frac{s}{p}$, and then making lim. $p = \infty$, gives the final limit approached by the use of many arcs.

Equation (68) then becomes:

$$a_n = a_o \left[1 - \left(1 - \frac{q}{p}\right)^{pn}\right]$$

and for $p = \infty$, this becomes:

$$a_n = a_o\,(1 - e^{-qn}) \qquad (75)$$

For comparison are added in Table IX the values of a taken from the exponential limit equation (75) and denoted by a.

From (70) follows:

$$q = \frac{s\,(T_2 - T_s)}{T_a - T_2 + s\,(T_2 - T_s)} = \frac{1}{1 + \frac{T_a - T_2}{s(T_2 - T_s)}} \qquad (76)$$

assuming then:

$T_a = 3600$; $T_2 = 1400$; $T_o = 400$, (12) gives:

$$q = \frac{1}{1 + \frac{2.2}{s}} \qquad (77)$$

substituting in (68) then gives:

$$\frac{a_n}{a_o} = 1 - \left[\frac{1}{1 + \frac{s\,(T_2 - T_s)}{T_a - T_2}}\right]^n = 1 - \frac{1}{\left(1 + \frac{s}{2.2}\right)^n} \qquad (78)$$

assuming then the desired relative concentration, as for instance:

$$b = \frac{a_n}{a_o} = \frac{2}{3}$$

(78) gives:

$$n = \frac{\log_{10}\frac{1}{1 - b}}{\log_{10} 1 + \frac{s\,(T_2 - T_s)}{T_a - T_2}} \doteq \frac{0.477}{\log_{10} 1 + \frac{s}{2.2}} \qquad (79)$$

The relative efficiency is:

$$\eta = \frac{a_n}{nqa_o} \qquad (80)$$

nq represents the part of the air which is exposed to the arc, and nq = const., thus would represent constant expenditure of electric energy, assuming that the same size of arcs is used.

TABLE IX. MULTIPLE ARCS

$T_o = 300$; $T_a = 3600$; $T_s = 400$; $s = 0.5$; $b = 10^7$
$q = 0.185$

5	885	1390	2.410	3.46	0.692
6	895	1395	2.670	3.84	0.640
7	898	1398	2.870	4.13	0.590
8	900	1400	3.034	4.37	0.546
9	900	1400	3.167	4.55	0.506
10	900	1400	3.278	4.72	0.472
11	900	1400	3.366	4.84	0.440
12	900	1400	3.437	4.95	0.412

TABLE X. MULTIPLE ARC

$T_o = 300$; $T_a = 3600$; $T_s = 400$; $T_2 = 1400$;
$s = 0.5$; $b = 10^7$

n	q	T_1	T_2	a	γ	η
1	0.33	300	1400	1.250	1.00	1.00
1	0.232	300	1065	0.870	1.00	1.00
2	.....	735	1400	1.540	1.77	0.885
1	0.203	300	970	0.763	1.00	1.00
2	.....	685	1280	1.372	1.80	0.90
3	.....	840	1400	1.851	2.43	0.81

The investigation of a_n, n, etc., at constant nq thus represents the effect of the arrangement of the arcs, or arc furnaces, in series or in multiple.

Table XI then gives, with the cooling constant s as parameter, and for the same values of $T_a = 3600$, $T_2 = 1400$ $T_s = 400$, $a_o = 3.75$ per cent, the values of q, n, nq, for $b = \frac{2}{3}$, that is, the final concentration $a_n = 2.5$ per cent NO.

TABLE XI. MULTIPLE ARCS

$T_a = 3600$; $T_s = 1400$; $T_c = 400$; $a_o = 3.75$; $f = \frac{1}{4}$

s =	0.05	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
q =	0 0222	0 0435	0.0833	0.120	0.154	0.185	0.215	0.241	0.267	0.290	0.313
n =	49 7	25 7	13.8	8.6	6.6	5.4	4.6	4.0	3.5	3.2	3.0
nq =	1 10	1.12	1 15	1.03	1 01	0.99	0.98	0.96	0.945	0.935	0.93
η =	0.62	0.60	0.58	0.64	0.66	0.67	0.68	0.695	0.705	0.71	0.72

As seen from this table, which is plotted in Fig. 10, the efficiency is best with the use of as small number of arcs in series as feasible. Thus, with four arcs in series, we get a concentration of 2.5 per cent at $q = 0.24$, and an efficiency of about 70 per cent. Thus, to double the NO concentration in the arc gases from the average of the single arc furnaces of 1.25 per cent to 2.5 per cent would require series connection of four furnaces, at a sacrifice of 30 per cent of output.

If then the cost (operation plus interest on the investment) of the absorption plant is 70 per cent, that of the furnace (including power, etc.) is 30 per cent, as has been stated, series connection of four arcs would give a reduction of cost of 35 per cent in the absorption plant but an increase of 13 per cent in the furnace plant, thus a resultant saving of 22 per cent in the cost, assuming the same type of furnace and absorption system.

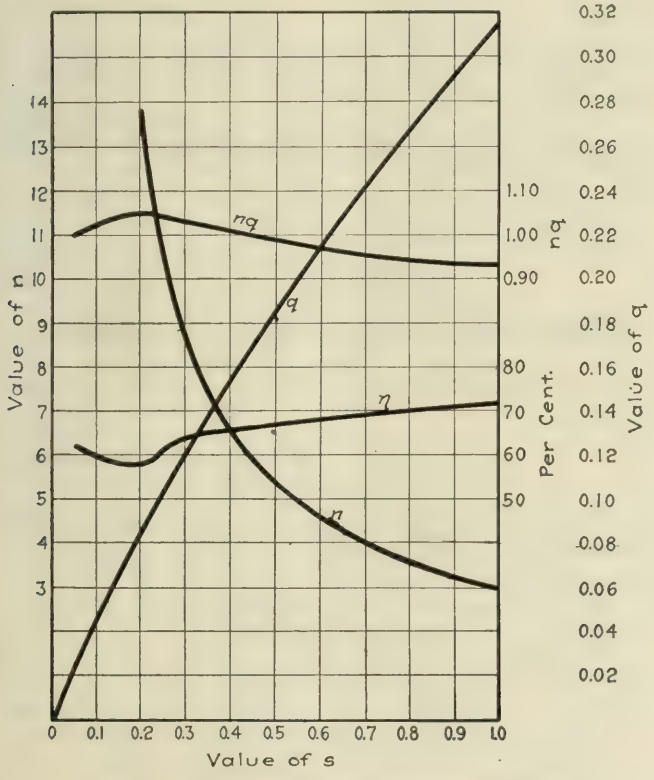

FIG. 10. MULTIPLE ARC NITRIFICATION

As furnaces are more quickly built than absorption systems, with the present plants it would permit in emergencies to double the capacity, within a short time, by commandeering more power—if these theoretical reasons are verified by experience.

Speculation on Cooling of Arc by Adiabatic Expansion and by Molecular Diffusion

When establishing an arc in air, the air in the path of the arc stream is raised to arc temperature, say 4000 deg. abs., and thereby expands in volume. If the arc is formed slowly, or moves slowly through the air, the air may expand and thereby be set in motion during its heating by the arc, so that the pressure in the arc stream remains constant, and the temperature rise occurs at constant pressure. If, however, the arc is established with extreme suddenness, the air would be heated to arc temperature before it had time to increase in volume by expansion, as a finite time is necessary to set the air in motion. In this case, the heating of the air in the arc stream would occur at constant volume, and the pressure in the arc stream would rise proportional to the temperature rise.[1] This would require materially less heat energy. The air would then expand and thereby drop in temperature by adiabatic expansion or, if the arc persists, additional heat energy will be required to maintain the arc temperature. In either case, the air, while being heated by the arc stream, is set in motion in expanding, and then, after falling again to atmospheric pressure, would continue to move, over-expand to a pressure below atmosphere, with corresponding drop of temperature, until the atmospheric pressure stops the further expansion, and the gas contracts again.

Probably, with the rapidly moving or rapidly started interrupted arcs of nitrogen furnaces, the actual condition is somewhere intermediate between constant pressure and constant volume heating.

As the cooling of the air in the arc stream by the expansion and over-expansion discussed above may lower the temperature down to or near the values where NO is relatively stable, it may be a factor in saving a large part of the NO concentration corresponding to the arc temperature equilibrium, and this would depend on the diameter, that is, the current of the arc, and the manner of its starting, moving, etc., so that the possible magnitude of the effect needs considering.

For this purpose it obviously will be sufficient to consider the air as an ideal gas, and apply the equations pertaining to such.

Thermodynamic Equations of Air as Ideal Gas

The general equation is:

$$pv = \frac{r}{M} T = RT \qquad (81)$$

where:

p = pressure, kg. per sq.m.
v = volume, cu.m. per kg.
T = abs. temperature.
M = molecular weight, = 29
r = gas constant = 845
R = 29.2

The adiabatic equation is:

$$pv^a = \text{const.} \qquad (82)$$

where:

a = adiabatic constant,
= 1.4 for air.

From (1) and (2) follow, for adiabatic expansion or compression between the limits p_o, v_o, T_o and p, v, T:

[1] In agreement wherewith would be the higher voltage required by a transient arc: the arc voltage rises with the pressure.

$$\frac{p}{p_o} = \left(\frac{v_o}{v}\right)^a = \left(\frac{T}{T_o}\right)^{\frac{a}{a-1}}$$
$$\frac{v}{v_o} = \left(\frac{p_o}{p}\right)^{\frac{1}{a}} = \left(\frac{T_o}{T}\right)^{\frac{1}{a-1}}$$
$$\frac{T}{T_o} = \left(\frac{p}{p_o}\right)^{\frac{a-1}{a}} = \left(\frac{v_o}{v}\right)^{a-1} \quad (83)$$

The adiabatic expansion energy is, when expanding or compressing adiabatically between the limits p, v, T, and p_2, v_2, T_2; p_o, v_o, T_o being one point of the adiabatic curve:

$$E = \int_1^2 p\,dv$$
$$= \frac{R}{a-1}(T_1 - T_2)$$
$$= \frac{p_o v_o}{a-1}\left[\left(\frac{v_o}{v_1}\right)^{a-1} - \left(\frac{v_o}{v_2}\right)^{a-1}\right] = \frac{RT_o}{a-1}\left[\left(\frac{v_o}{v_2}\right)^{a-1}\left(\frac{v_o}{v_2}\right)^{a-1}\right]$$
$$= \frac{p_o v_o}{a-1}\left[\left(\frac{p_1}{p_o}\right)^{\frac{a-1}{a}} - \left(\frac{p_2}{p_1}\right)^{\frac{a-1}{a}}\right] = \frac{RT_o}{a-1}\left[\left(\frac{p_1}{p_o}\right)^{\frac{a-1}{a}}\left(\frac{p_2}{p_o}\right)^{\frac{a-1}{a}}\right]$$
$$= \frac{RT_1}{a-1}\left[1 - \left(\frac{v_1}{v_2}\right)^{a-1}\right] = \frac{RT_2}{a-1}\left[\left(\frac{v_2}{v_1}\right)^{a-1} - 1\right]$$
$$= \frac{RT_1}{a-1}\left[1 - \left(\frac{p_2}{p_1}\right)^{\frac{a-1}{a}}\right] = \frac{RT_2}{a-1}\left[\left(\frac{p_1}{p_2}\right)^{\frac{a-1}{a}} - 1\right] \quad (84)$$

If the energy of adiabatic expansion is converted into velocity, the kinetic energy of the velocity s being, per unit weight or kg.

$$E = \frac{s^2}{2g} \quad (85)$$

where
$g = 9.83$
= acceleration of gravity,
it follows from (85) and (84):

$$s = \sqrt{2gE} = \sqrt{\frac{2gR}{a-1}(T_1 - T_2)} \quad (86)$$

$= 37.7\sqrt{T_1 - T_2}$ meter seconds for air,
as the velocity of adiabatic expansion.

At constant pressure p' the expansion energy of unit weight (kg.) of gas between volumes v_1 and v_2 is:

$$E = p'(v_2 - v_1) \quad (87)$$

Applying now the gas equations to the thermodynamic phenomena occurring in a suddenly started and suddenly interrupted arc stream:

Let a gas cylinder of diameter d_1, of pressure p_1, and temperature T_1 be suddenly heated to temperature T_2, at constant volume: $v_2 = v_1$, by an arc of stream diameter d_1.

The pressure of the gas stream is thereby raised to: (81)

$$p_2 = p_1\frac{T_2}{T_1} \quad (88)$$

The gas then expands adiabatically back to the pressure p_1 of the surrounding atmosphere and thereby increases in volume and drops in temperature to: (83)

$$v_3 = v_1\left(\frac{p_2}{p_1}\right)^{\frac{1}{a}}$$
$$T_3 = T_2\left(\frac{p_1}{p_2}\right)^{\frac{a-1}{a}} \quad (89)$$

and the diameter of the gas stream thereby increases to:

$$d_3 = d_1\sqrt{\frac{v_3}{v_1}} = d_1\left(\frac{p_2}{p_1}\right)^{\frac{1}{2a}} \quad (90)$$

In expanding then adiabatically, from p_2, v_2, $=v_3$, T_2, to $p_3 = p_1$, V_3, T_3, the gas gives the energy: (84)

$$E_o = \frac{R}{a-1}(T_2 - T_3) \quad (84)$$

Of this, the energy (87):

$$E' = p_1(v_3 - v_1) = RT_1\left[\left(\frac{p_2}{p_1}\right)^{\frac{1}{a}} - 1\right] = RT_1\left[\left(\frac{T_2}{T_1}\right)^{\frac{1}{a}} - 1\right] \quad (91)$$

is consumed in pushing away the surrounding atmosphere, thus leaving the energy:

$$E = E_o - E_1$$

This energy E, doing no external work, becomes kinetic, and the gas thus assumes the velocity.

$$s = \sqrt{gE} = \sqrt{g(E_o - E_1)}$$

When the expanding air has again reached atmospheric pressure p_1, at temperature T_3, it thus has the velocity s, and continues to move with this velocity radially outward, thus over-expands, until its kinetic energy has been spent in pushing away the surrounding atmosphere of pressure p_1, at pressure p_4, volume v_4 and temperature T_4.

At this point, the work done in pushing away the surrounding atmosphere: (81) and (83)

$$E'' = p_1(v_4 - v_1) = RT_1\left[\frac{v_4}{v_1} - 1\right] = RT_1\left[\left(\frac{T_2}{T_4}\right)^{\frac{1}{a-1}} - 1\right] \quad (92)$$

has become equal to the total energy of expansion:

$$E_{oo} = \frac{R}{a-1}(T_2 - T_4)$$

Thus,

$$T_1\left[\left(\frac{T_2}{T_4}\right)^{\frac{1}{a-1}} - 1\right] = \frac{T_2 - T_4}{a-1} \quad (93)$$

This gives the temperature T_4, and herefrom the pressure p_4 and the volume v_4, and the diameter d_4 of the gas column.

The average velocity of expansion from volume v_1 to v_3 to v_4 is (assuming parabolic law):

$$s_0 = \tfrac{2}{3}s$$

TABLE XII. ADIABATIC EXPANSION OF ARC

$p_1 = 10_4 = 1$ kg. sq.cm.
$T_1 = 400$ deg. abs.
$v_1 = \frac{RT_1}{p_1} = 1.168$ cu.m.
$T_2 = 4000$ deg. abs.
$p_2 = 10$ kg. sq.cm.
$v_2 = v_1$
$T_3 = \frac{T_2}{1.93} = 2080$ deg. abs.
$p_3 = p_1 = 1$ kg. sq.cm.
$v_3 = 5.18\,v_1 = 5.97$ cu.m.

$E_0 = 140{,}200$ kg.m.
$E_1 = 48{,}000$ kg.m.
$E = 92{,}200$ kg.m.
$s = 952$ m.sec.
$s_0 = 635$ m.sec.
$T_4 = 1255$ deg. abs.
$p_4 = \frac{p_2}{57.6} = 0.184$ kg.sq.cm.

The average distance traveled by the expanding gas of the cylindrical column is:

From $\frac{d_1}{3}$ to $\frac{d_3}{3}$ to $\frac{d_4}{3}$

or $\frac{d_3 - d_1}{3}$ and $\frac{d_4 - d_3}{3}$

At average velocity s_o, this gives the time, during which the gas expands:

$$t_3 = \frac{d_3 - d_1}{2s} \qquad t_4 = \frac{d_4 - d_3}{2s} \tag{94}$$

and as the temperature drop during the two periods of gas travel is:

$$T_2 - T_3 \text{ and } T_3 - T_4,$$

it gives the average rate of cooling, or the cooling constants:

$$b_3 = \frac{T_2 - T_3}{t_3} = \frac{2s\,(T_2 - T_3)}{d_3 - d_1} \qquad b_4 = \frac{T_3 - T_4}{t_4} = \frac{2s\,(T_3 - T_4)}{d_4 - d_3} \tag{95}$$

and from the cooling constants b follows, by the previous considerations, the residual NO concentration a, which escapes dissociation.

As an instance may be considered, for arc temperature $T_2 = 4000$, and initial air temperature $T_1 = 400$ at atmospheric pressure $p_1 = 10^4 = 1$ kg. per sq.cm. (which is about the average atmospheric pressure), the values corresponding to various arc diameters from $d_1 = 0.1$ to $d_1 = 10$ cm., for the values:

$$d_1 = 0.1 \;\; 0.2 \;\; 0.5 \;\; 1 \;\; 2 \;\; 5 \;\; 10 \text{ cm.}$$

The values are recorded in Table XII, showing a decreasing recovery $\frac{a}{a_o}$ with increasing diameter of the arc stream.

Substituting in (86)

$$T_2 = 0$$

gives:

$$s_o = \sqrt{\frac{2gR}{a-1}}\,T = 37.7\sqrt{T} \tag{96}$$

as the limiting velocity of expansion from temperature T into a perfect vacuum, representing the conditions where all the heat energy of the molecules is converted into the kinetic energy of motion, and this velocity s then represents the molecular energy of the heat energy.

For the arc temperature

$$T = 4000$$

This gives:

$$s_o = 2380 \text{ m.sec.}$$

This would then be the velocity, with which the molecule of the hot gas diffuses into the surrounding cold air.

As the molecular velocities are in all directions, the component of the velocity in the radial direction is only

$$s_1 = \frac{2}{\pi}\,s_o = 1510 \text{ m.sec.}$$

With an arc diameter of $d_1 = 1$ cm., thus an average distance of <0.5 cm. to travel, this would give a time of travel of $t = <3.3$ microsec. At a surrounding air temperature of 400 deg. abs., thus a temperature difference of 3600 deg., this would give a cooling constant of $b = <10.9 \times 10^8$. This would give a residual concentration of $a = 5.1$ per cent, out of $a_o = 7.95$ per cent, corresponding to 4000 deg. abs., or 64 per cent.

Thus, the highest concentration which would be expected from a 1-cm. arc by molecular diffusion would be less than 5.1 per cent, and this only if the gas pressure is so low that the free path of the molecules is of the magnitude of 1 cm.

Assuming then an arc terminates in the throat of an expansion nozzle, and the gases are sucked through the arc into the nozzle, expanding therein to lower pressures and thus lower temperatures.

Let p_o = initial pressure of the gas, and T_o = arc temperature at this pressure.

Expanding to lower pressure p, and corresponding temperature T, the expansion velocity is, by (86):

$$s = \sqrt{\frac{2gR}{a-1}\,(T_o - T)} \tag{86}$$

The section of the gas stream at velocities s is:

$$S = \frac{v}{s}$$

where v is the volume per unit time.
as by (83):

$$\frac{v}{v_o} = \left(\frac{T_o}{T}\right)^{\frac{1}{a-1}}$$

It is:

$$S = \frac{v_o T_o^{\frac{1}{a-1}}}{s T^{\frac{1}{a-1}}}$$

and by (86)

$$S = \frac{v_o T_o^{\frac{1}{a-1}}}{\sqrt{\frac{2gR}{a-1}}}\,T^{-\frac{1}{a-1}}\,(T_o - T)^{-0.5}$$

and this section is a minimum for:

$$\frac{dS}{dT} = 0, \text{ or: } \frac{d}{dT}\left[T^{\frac{2}{a-1}}\,(T_o - T)^{\frac{1}{a-1}}\right] = 0$$

this gives:

$$\frac{T_1}{T_o} = \frac{2}{a+1} = \frac{5}{6} \text{ for air} \tag{97}$$

This gives the temperature at the nozzle throat, and by (83):

$$\frac{p_1}{p_o} = \left(\frac{T_1}{T_o}\right)^{\frac{a}{a-1}} = \left(\frac{5}{6}\right)^{3.5} = 0.528 \tag{98}$$

That is, the pressure at the nozzle throat is 0.529 p_o. The velocity at the nozzle throat is, by (101) or (86):

$$s_1 = 37.7\sqrt{T_o - T_1} = \frac{37.7\sqrt{T_o}}{\sqrt{6}} = 15.4\sqrt{T_o} \tag{99}$$

Thus, at arc temperature $T_o = 3600$ deg. abs.,

$$s_1 = 924 \text{ m.sec.}$$

If now the arc terminates at the nozzle throat, and the arc gases further expand to the pressure p and temperature T, Table XIII gives values of $\frac{T}{T_o}$ for various values of $\frac{p}{p_o}$ by equation (83).

Assuming now that the divergence of the nozzle is such that the temperature along the nozzle drops by expansion at the rate of $\delta = 1000$ deg. per cm. The

TABLE XIII. ELECTRO-THERMAL EQUILIBRIUM

I

Cooling rate: $b = 10^5$ deg. per sec.

$$T_1 = \frac{\log_{10}(33 - a) + 12.971}{5.731} \times 10^3$$

Residual contentration, per cent: a =	0	4	8	12	16	20	24	28	30	32	32.5	32.9
Arc temperature, deg. abs.: T_1 =	2535	2525	2515	2500	2480	2460	2430	2380	2350	2270	2215	2090

cooling constant along the path of the expanding gas then would be

$$b = 100\delta s = s \times 10^5 \qquad (100)$$

Where the factor 100 reduces from meters to centimeters.

Assuming as an instance an expansion ratio: $\frac{p}{p_o} = 0.2$.

This would give a temperature ratio: $\frac{T}{T_o} = \left(\frac{p}{p_o}\right)\frac{1}{3.5} = 0.631$.

Hence, at $T_o = 3600$, an expansion temperature: $T = 2270$ deg. abs., and at this temperature the reaction velocity has already dropped so that by rapid further cooling, little loss may be expected.

This gives a velocity, by (86): $s = 37.7\sqrt{T_o - T} = 1375$ m.sec.

This gives a cooling rate: $b = 1.375 \times 10^5$.

Hence a residual concentration: $a = 4.5$ per cent. While the throat velocity: $s_1 = 924$, would give a cooling rate $b_1 = 0.924 \times 10^5$.

Hence a residual concentration: $a_1 = 4.4$ per cent.

Thus an average NO concentration of about 4.45 per cent might be expected, while the initial concentration, at 3600 deg. abs., is 6.15 per cent.

It is interesting to note that the rapid expansion by terminating the arc in the throat of an expansion nozzle would give very high concentrations, that is, save most of the NO produced by the arc, without diluting the gases with masses of cold air, and thereby lowering the concentration and thus requiring the enormous absorption plant: a concentration of 4.45 per cent would reduce the size of the absorption plant—which is the largest part of the cost of installation—to about one-quarter of the present size.

Thus this method requires further experimental investigation regarding its feasibility.

Water-cooled nozzles of a high ferrotungsten would probably stand the temperature for a considerable time, especially if the throat is made replaceable. A turbine wheel in front of the nozzle would further cool the gases and abstract their velocity, without any temperature rise due to the destruction of their kinetic energy. A steel wheel would probably stand the temperature of the gases indefinitely, as it is exposed to it only intermittently for a very short time.

When expanding from atmospheric pressure p_o to $p = \frac{1}{5}$ to $\frac{1}{10}$ of an atmosphere, it would need recompressing the gases before they can be sent into the absorption system and then returned into the air. It thus would be preferable to initially compress the air to a pressure of $p_o = 5$ to 10 atmospheres, and then expand to atmospheric pressure. The turbine wheel abstracting the kinetic energy of the gas jet would then, if of reasonable efficiency, give ample power for the initial compression.

However, in this case the serious question arises whether an arc at 5 to 10 atmospheres pressure is not materially hotter than one at atmospheric pressure, and as the result thereof the temperature drop during the adiabatic expansion would not be sufficient to carry down to safe temperatures.

An investigation of the temperature of air arcs at various pressures would therefore be of primary importance.

(*Part IV, the last of the series on theoretical study of nitrogen fixation by the electric arc, will be published in our next issue.*)

Phosphate Reserves of Pacific Islands

According to a memorandum laid on the table of the New Zealand House of Representatives by the President of the Board of Agriculture, the reserves of phosphate of the Island of Nauru, in the Pacific, are sufficient to meet the demands of the world for two hundred years. Information obtained from a reliable source, says the *Board of Trade Journal*, indicates that anything from 80,000,000 to 100,000,000 tons are available, and possibly more. The quality of the phosphate is said to be of the highest grade (85 to 86 per cent), and it is claimed that this island contains the largest known quantities of high-grade phosphate in the world. The present output of the island has been somewhat interfered with by the war, but the average yearly production is in the neighborhood of 150,000 tons.

There are several phosphate islands in the Pacific, these including Ocean Island, where the Pacific Phosphate Co. has the mining rights, this company also holding an interest in a French company which works the Makatea Island deposits; Christmas Island; Angaur Island, which, according to a German authority, contains 2,500,000 tons ranging from 81 to 83.6 per cent, though another authority places the available phosphate between 300,000 and 600,000 tons; Surprise Island; Clipperton Island; Walpole Island, and Malden Island. Christmas Island, referred to above, must not be confounded with an island of the same name near Java.

Phosphate Deposits in the Netherlands

Phosphate deposits have been discovered in the eastern part of Holland, at a place called Ootmarsum, in the Twente District. About thirty tons of 15 to 20 per cent phosphate are being produced each day, and are being sold locally at prices corresponding to the prices of imported phosphate. The stratum varies from 7 in. to 3 ft. in thickness, but on account of the fact that it is not continuous the work of extracting the rock is very expensive. In some places the stratum is on the surface, in others it is as much as 25 ft. beneath the surface.

DAM SITES AND FIXED NITROGEN PLANTS

Muscle Shoals Hydro-Electric Development

Wilson Dam on the Tennessee River in Alabama—Corps of Engineers, U. S. Army, Making Rapid Progress Toward Completion in 1922—Power Generated Will Reduce Operation Costs at Nitrate Plant No. 2

BY CHESTER H. JONES

MANY persons interested in the discussions at Washington over the fixed nitrogen situation are not fully informed as to the location of the Government nitrate plants and water-power development and the relation between them. The name Muscle Shoals has been used in referring to both water-power and chemical plants, causing much confusion. The map shown herewith will clarify this misunderstanding.

Muscle Shoals originally designated the stretch of river up stream from the city of Florence and was later also applied to the permanent village erected by the Government on the 2,200-acre tract in connection with Nitrate Plant No. 2. It is here the $70,000,000 cyanamide plant now stands idle. The rated capacity is 110,000 tons of ammonium nitrate (38,500 tons fixed nitrogen) per annum. The process has proved successful and the plant is practically completed.

Tract No. 1 (1,700 acres), southwest of Sheffield, is the site of Nitrate Plant No. 1, where the modified Haber process plant was installed by the Ordnance Department, U. S. Army, under the advisement of the General Chemical Co., and a permanent village was built. This plant, also standing idle, has a capacity of about 18,350 tons of ammonium nitrate (6,425 tons fixed nitrogen) annual production and the construction is completed, with a total cost of property, including village, of about $14,000,000. The process did not operate successfully, but may be developed to do so through research.

Nitrate Plants Nos. 3 and 4, located at Toledo and Cincinnati respectively, were partially completed in the erection of factory buildings. These are being used as storehouses for ordnance material. The bills now before Congress refer only to the industrial properties in Alabama and research laboratories elsewhere.

On June 3, 1916, Section 124, H. R. 12,766, carrying an appropriation of $20,000,000, became a law (Public Document 85) and was directed chiefly toward the erection of the dams, although about $6,000,000 was expended in building Plant No. 1. The money for Plant No. 2 was taken from another general war fund of over $300,000,000 subsequently appropriated by Congress.

The nitrate plants have always been under the direction of the Nitrate Division, Ordnance Department,

SOUTH ABUTMENT—EFFECTS OF BLASTS IN DRILL WELL HOLES

LOOKING NORTH TOWARD JACKSON ISLAND—MAIN CAMP ON NORTH BANK

CONCRETE FORMS FOR HIGH LEVEL CONSTRUCTION BRIDGE ON JACKSON ISLAND

while the dams were handled, separately and apart, by the Corps of Engineers, U. S. Army.

Practically nothing was accomplished toward construction of the dams during the war, because it was known that water power could not be secured in time to meet the emergency. The work was therefore delayed until such time as labor conditions became more favorable.

The operations at the Wilson Dam (Dam No. 2) are now proceeding under the immediate direction of Colonel Lytell Brown at Muscle Shoals, who reports to the Chief of the Corps of Engineers in Washington. About 5,000 workmen are engaged. Prior to Jan. 1, 1920, $3,679,000 was expended, leaving about $14,000,000 on hand. It is roughly estimated that the total cost of this dam will

LOOKING SOUTH, COFFER DAM NO. 1 AND JACKSON ISLAND

be somewhat in excess of $20,000,000 under existing conditions and the work completed in 1922. No immediate construction will be carried out on Dams No. 1 and No. 3 and the navigation features.

Wilson Dam Details

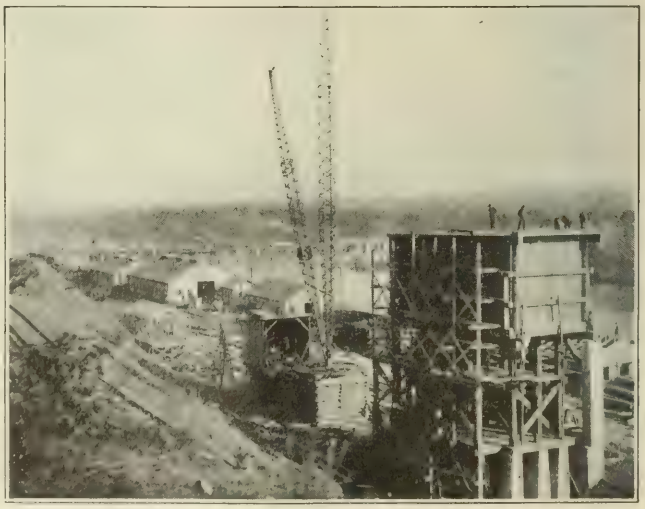
The development is run-of-river, there being no storage capacity for reserve water. The plans of construction closely follow those outlined in the report prepared by Major H. Burgess, Corps of Engineers, and submitted to Congress through military channels during June, 1916, House Document 1,262, Sixty-Fourth Congress, First Session, Serial 25; 6,979.

This report embraces the whole project of three dams and canal through the river shoals. The old canal is inoperative for about six months each year and is limited to the passage of smallest river boats. The navigation improvement will require the eventual erection of Dam No. 3.

The Wilson Dam (No. 2), crossing Jackson Island (the latter shown in dotted outline on the map), has a spillway crest of 3,080 ft., a height of 94 ft. and a total base of 177 ft. Of this base dimension 57 ft. is

DOWNSTREAM HALF OF COFFER DAM NO. 1, PUMPED OUT, AND HIGH LEVEL CONSTRUCTION BRIDGE

taken up by a spillway apron, anchored to the river bed and provided with necessary weepholes. While the river bed is composed of country rock, harder than concrete, it is liable to become dislodged in large blocks. Hence the wide apron is necessary.



NORTH SHORE MIXING PLANT, SHOPS AND WAREHOUSE

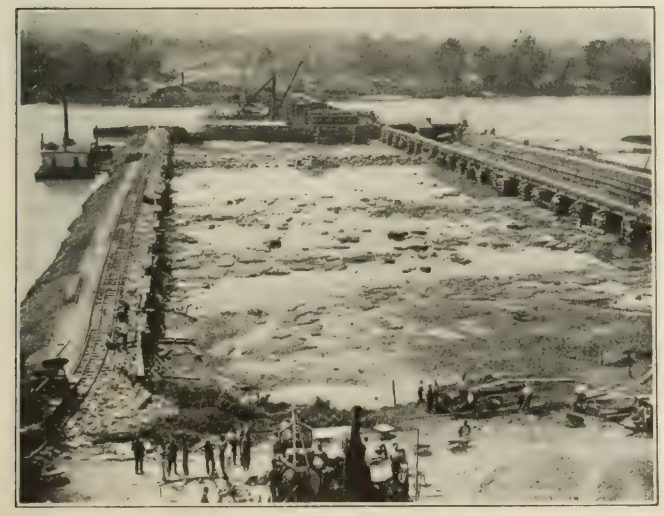
UPSTREAM HALF OF COFFER DAM NO. 1, PUMPED OUT

The design provides for a maximum depth of water on the crest of 13 ft. at a river discharge of 500,000 cu.ft. per sec. The wasteway section will carry 10,000 cu.ft. per sec. The working head is between 95 and 92 ft.

Power Arrangements

The power house will contain foundations for twelve 40,000-hp. water turbines, single runner type. The estimated primary power is 100,000 kw., with a total primary and secondary power of 300,000 kw.

The 60,000-kw. steam plant on the site of Nitrate Plant No. 2, connected by an 80-mile transmission line with the 30,000-kw. steam plant on the Black Warrior River, may be operated in conjunction with the hydro-electric units. Both steam plants, together with the transmission line, are Government properties and have been tested and run in connection with the chemical process operation.



COFFER DAM NO. 1, PUMPED OUT, SHOWING CHARACTER OF ROCK BOTTOM

The accompanying illustrations give an idea of the progress made on the Wilson Dam at the beginning of 1920. A large number of the workmen occupy living quarters in the village at Nitrate Plant No. 2. Several hundred thousand dollars' worth of materials left over from the construction work at the chemical plant is being turned to good use in the work at the dam.

The writer is indebted to Colonel Pillsbury for information which he supplied during the preparation of this article.

Legal Notes

By Wellington Gustin

A Lesson on Aluminum and Sales Contracts

The Supreme Court of Errors of Connecticut has handed down its decision in the suit brought by the Brown Bag Filling Machine Co. against the United Smelting & Aluminum Co. for breach of contract to buy "rod aluminum." (107 Atl., 619.)

The facts out of which this action arose, as stated by the court, appear to be that in February, 1916, the plaintiff had on hand about 34,000 lb. of aluminum rods of various sizes, and the right by contract to about 4,400 lb. of aluminum not drawn and to be specified. Plaintiff was not a dealer in the metal, but had this quantity on hand as a result of his failure to place a certain contract requiring the use of aluminum.

Acceptance of Part of Order

It was admitted that about Feb. 18, 1916, the parties entered into a written contract by which the defendant agreed to buy of the plaintiff 34,078 lb. of aluminum rods at 80c. per lb., to be drawn in sizes to be specified by the purchaser. Now, 1,490 lb. of this aluminum was delivered to and received by the defendant, not needing to be changed in size.

This action was brought to recover damages by the refusal of the defendant to take and pay for the balance of the aluminum rod described in the contract. The defendant smelting company in defense contended that the aluminum rod of plaintiff was not pure aluminum, and set up a counter-claim for damages from plaintiff's failure to deliver pure aluminum. Now, the substantial controversy was whether the contract called for pure aluminum or the aluminum rods of commerce as understood in the aluminum trade, and whether, by acceptance of a part of the rods, the defendants in law accepted the whole.

In the second count of his complaint the plaintiff sought to recover the price of the rods and coils of aluminum wire which were delivered. The item 4,400 lb. became the subject of a separate contract as to which no question arises in this case.

Does Rod Aluminum Mean Pure Aluminum?

The order given by defendant described the material as "rod aluminum," to be "drawn to specifications." By the direction of the defendant the plaintiff sent the rod to the mill to be redrawn according to specifications furnished by the defendant. The defendant then requested that two sample coils of $\frac{5}{32}$-in. wire be drawn and sent to it for examination. The plaintiff advised defendant that the manufacturer was of the opinion that the rods were too hard to furnish a satisfactory wire of that size. However, two coils of wire were drawn and sent to the defendant, who refused to give further specifications or to accept the wire at the mill on the ground that the rod aluminum offered by the plaintiff was not of the quality purchased.

The Supreme Court said the case turns upon the meaning of the terms of the written contract, it having appeared that the trade designation of the rods of plaintiff was 15S or 15SH. Now, 15S is a grade of alloyed aluminum containing about 86½ per cent pure aluminum. H is the symbol for annealed hard. O is a symbol for annealed soft, while 2S is the symbol for commercially pure aluminum, that being 98 to 99

per cent aluminum. In its narrow sense the question was whether rod of the 15S quality, or alloy, in the trade answered to the description and filled the order for "rod aluminum." The jury in the trial court found that it did, or found an acceptance of the rod by the defendant, and rendered a verdict for the plaintiff on both counts of the complaint. From this verdict the defendant appealed.

On the appeal the Supreme Court found that the negotiations were entirely in writing, including letters and telegrams, and shown in the evidence. They conclude with the direction by the defendant to ship the rod to the mill for redrawing and without exception referred to the material as "rod aluminum." If, in accordance with the meaning of the term in the trade, the aluminum in question was rod aluminum, the contract was met by the plaintiff, said the court. Much testimony by witnesses skilled in the business was given at the trial as to whether "rod aluminum," either standing alone in the purchase order or with the additional words "to be drawn to our specifications," without further description, had a definite established meaning in the trade, and if so whether the meaning was pure aluminum or a standard alloy, or, the court said, to put it more definitely, whether the alloy 15S, containing 86½ per cent of aluminum, furnished or offered by the plaintiff, in the trade filled a contract for rod aluminum.

Points to Be Considered by the Jury

Further, the court said the 1,490 lb. was shipped to defendant, as needing no redrawing, and upon its order, and resold by defendant in the original package. Now, the defendant claimed that this was sold under the belief that it was pure aluminum, and that two months later its purchaser made a claim based upon the fact that these rods were not pure, but were only 93 per cent aluminum. However, there was evidence, the court said, from which the jury might have found that no complaint was ever made about this rod by defendant and that it was accepted as part of the entire purchase. Further, the court held, the jury was entitled to consider from the negotiations whether the order was not for the specific goods that plaintiff had, and that if the rods delivered or offered were those and only those the plaintiff had on hand when plaintiff made its first inquiry, and were in fact rod aluminum as understood in the trade, then the plaintiff filled its contract, whatever the specific alloy might be. Upon the charge as given by the trial court the jury was fully warranted in rendering a verdict for the plaintiff, said the Supreme Court.

But the defendant contended that the trial court erred in instructing the jury that it might take into account the experience, or lack of experience, of the parties in the aluminum trade in determining the meaning of the term "rod aluminum" in the contract. It claimed that this language would mislead the jury to the injury of the defendant, as tending to excuse the plaintiff for its lack of knowledge if otherwise the facts should turn out to be to his disadvantage. And so the court held. It said that upon the facts generally no special meaning was presumed to be attached to the term other than the ordinary meaning as used in the trade, to which both parties were bound, whether ignorant or skilled.

Since the sole question was whether "rod aluminum" means pure aluminum the lower court was held to have erred in instructing the jury to determine whether the words "to be drawn to our specifications" had any distinct well-known meaning in the trade, applied to both size and composition, or to size only, and whether the plaintiff knew or ought to have known that the words were used in such special sense. Further, the Supreme Court held that the sale being of specific goods designated as "rod aluminum" in the written contract and in the written negotiations leading up to the contract, it was the duty of the seller to furnish "rod aluminum" as that term was ordinarily used in the trade.

On the point as to the receipt and retention of a portion of the goods shipped by the plaintiff to defendant the court held that the retention of possession without any claim indicating that the buyer had any fault to find with the goods was sufficient to justify instructing the jury that under the circumstances such retention amounted to an acceptance.

Again, the lower court directed the jury's attention to letters bearing on the construction the parties took of the contract. These appeared to be self-serving letters, said the court, and not a practical construction of the contract agreed upon by the parties. They greatly favored the plaintiff, and since there was no ambiguity in the contract other than in the meaning of a technical trade term, the Supreme Court held this erroneous.

On the proposition that defendant's acceptance of a part of the goods under the order was an acceptance of the whole, the court held that the acceptance of a single lot of "rod aluminum" did not preclude the buyer from refusing to accept subsequent deliveries which in fact did not conform to the contract.

Controversy as to Damages

Some controversy arose over the court's instruction as to damages, which said: "Such damage would include whatever loss the plaintiff has sustained by reason of the loss of his bargain." But this was followed by more: "Damage for breach of a contract to buy goods ordinarily consists of the difference between the contract price and the market value of the goods at the time the buyer ought to have taken them."

The court held this not to be error and as following the sales act. However, it had been agreed between the parties that the plaintiff would claim damages on a market value of 50c. a lb. for the rods the defendant refused to take, and that the defendant on its counter claim would base its claim at $1.12½ per lb. for pure aluminum which it claimed to have bought; the contract price being 80c. per lb.

However, because of the error pointed out by the Supreme Court, the judgment was set aside and the case remanded.

New Source of Food Supply

Prof. P. W. Claassen of Cornell University published an article in a late number of the *Scientific Monthly* on "A Possible New Source of Food Supply," in which he called attention to an excellent, palatable flour from the roots of the common cat-tail *(Typha)* that grows abundantly in swamps. There are in the United States exclusive of Alaska, about 139,855 square miles of swamp land, and thousands of acres of this land are cat-tail marshes. An ordinary cat-tail swamp would yield 5,500 lb. an acre of edible flour which has substantially the same food value as corn or rice flour. The flour is said to be pleasing and palatable. The Indians used it freely.

Preventing Accidents in Gas Plants*

By J. F. Conner

THE title may lead persons unacquainted with the operation of gas plants to assume that employment in such plants is an extra-hazardous occupation, fraught with unusual danger. With few exceptions, the accident hazards met in gas plants do not materially differ from those found in other industries where mechanical and construction operations are the rule.

My conclusion in this respect is based on experience gained from a close acquaintance with such operations, receiving reports of accidents and investigating their causes, and from making accident hazard inspections of many gas plants.

Inherent Hazards of the Industry

The industry has, of course, inherent hazards. There are certain zones in gas works where in the course of operation pockets of gas may accumulate and, with the admixture of air, serious explosive hazards may form. Precautions should be taken against such conditions arising. The ventilation, lighting and the lighting system of such zones are questions for consideration. Such places should be as well ventilated as conditions will permit. In the lighting system, approved types of keyless socket, vapor-proof globe electric lamps with remote switch controls should be used, to guard against the possibility of the gaseous atmosphere being fired by an electric arc. Warning signs of size sufficient to attract attention, cautioning against smoking and the carrying of naked flames in such zones, should be posted in conspicuous places.

Precautions Against Dust Explosions

Like precautions should also be taken to guard against dust explosions in coal crusher rooms and pits where the air may be heavily charged, especially while the crushers are in operation, with minute particles of carbon which may be ignited and exploded by contact with an exposed flame. Dust explosions, while infrequent in gas plants, have been known to occur frequently in other industries with disastrous results.

It may be unnecessary to state that all warning signs should be kept in clear, legible condition if any benefit is to be derived from their posting. The writer has found, in the course of inspections, instances of lettering on painted wooden signs having become illegible from exposure to weather, and enamelled metal signs covered by accretions of smut and dust.

Respirators for Emergency Work

Emergency conditions may arise which will require working against live gas. In such instances, the workman should be protected by a suitable type of respirator. The same precaution should be taken when a workman is required to enter any gas-charged atmosphere and in every instance he should be under the clear observation of a person outside the danger zone, who should be prepared to render immediate assistance. Oil and other tanks in which gases are present should, where conditions will permit, be first purged by steam and well ventilated before entrance is made to such enclosure. Life lines can in such work be used to advantage.

Generally speaking, gas plants are usually well guarded mechanically. Occasionally, however, accidents occur on machinery due to guards being temporarily removed during repairs and failure to replace guards before putting the machines in operation again, or possibly to an exposure being considered too remote to warrant guarding.

Simple Hazards Cause Most Accidents

A review of cases reported shows that the causes responsible for the greater number of accidents are due to the simple hazards found in all industrial establishments such as tripping, falling, slipping, and lifting, protruding nails, to the use of defective hand tools, ladders, scaffolds and makeshift supports that give insecure footing, and other like minor hazards, and to disregard of instructions to wear goggles when engaged in work in which the eyes are exposed to flying particles or splashing liquors.

Education the Greatest Safeguard

The safeguarding of machinery and the installation of other mechanical devices for the prevention of accidents is unquestionably a necessary measure in any well-ordered plant, but in many cases the guards cannot be made absolutely fool-proof, so that in the final analysis, the greater reliance for preventing accidents must be placed on the human agency. If we are to continue to look forward to a reduction in the accident frequency, greater efforts must be made to educate the workman to know the dangers that beset him and others, from carelessness, thoughtlessness, and inattention on his part, and to arouse and maintain the accident prevention spirit in him.

Methods of Reaching the Workmen

How we shall best reach the workmen by educational propaganda is a question of personal opinion. Reasoning with the men collectively is usually attended by good results. In obdurate cases, however, resort to individual approach brings the best results. We should not, however, be too hasty in censure of the workman for apparent indifference to safety. He possibly may be influenced by environment and be reflecting the attitude of his superiors to this important question. The problem, to my reasoning, should first be brought convincingly to the attention of the man higher up, the man directly in charge of the operation. If he meets it, as he should, in a spirit of serious interest and by precept and example sets the standard for his subordinates, lets it be known that he is keenly alive to any failure or disinterestedness on their part to shoulder their duty, the indifference, if any, of the foremen and sub-foremen will quickly vanish and those in positions of responsibility will, figuratively speaking, be standing on their toes and showing greater activity toward preventing accidents. The interest they show is bound to be reflected in the workmen and with the environment of good housekeeping, a place for everything and everything in its place, which must of necessity be part of the program, there will come a subconscious awakening of the prevention spirit in the workmen and that is the dominating factor in preventing accidents.

Team work as outlined means co-operation. When the force of co-operation is behind the punch for safety, the fight for accident prevention is soon won.

*Paper read before the Eighth Annual Safety Congress of the National Safety Council, Cleveland, Ohio, Oct. 3, 1919 (slightly abridged).

Safety Supervisor,
United Gas Imp. Co.,
Philadelphia, Pa.

Explosion Hazard in Steel Mills From Partly Consumed Coal Dust

FOR many years natural gas has been the principal fuel used in the heating furnaces in those mills located in the Pittsburgh district which manufacture bolts, nuts, rivets, picks, mattocks and small forgings. For a number of years the steady supply of this fuel has been more or less interrupted owing to the increased demand for domestic use and to the increasing difficulty in securing an adequate amount of natural gas.

This condition has led a number of the steel companies to substitute pulverized coal as a fuel for the furnaces. Elaborate installations have been made for pulverizing the coal and conveying it to the furnaces. Soon after the furnaces commenced to operate with pulverized coal, large quantities of fine dust began to accumulate on the platforms over the furnaces, the roof trusses, on the outside of the various pipe lines, electric cables and even on the roofs of the buildings.

Some of the companies, becoming alarmed, requested the Bureau of Mines to make an investigation to ascertain the liability of this dust to cause an explosion. While conducting this investigation, an explosion occurred in another mill which caused the death of one man and severely burned two others.

A report of this investigation by L. D. Tracy is included in the *Monthly Reports of Investigations* for December, 1919.

Eleven samples of the dust (which for convenience has been termed "mill dust") from various locations in the different mill buildings were taken and submitted to chemical analysis, microscopic examination and also to flame and explosion tests. Table I shows the range of the proximate analyses of these samples of mill dust, compared with analyses made upon five samples of the pure coal dust, before passing into the furnaces. The inference drawn from a study of these figures, namely,

TABLE I. PROXIMATE ANALYSES OF COAL DUST

	Mill Dust, per Cent	Pure Coal Dust, per Cent
Volatile matter	6.3 to 23.54	30.50 to 36.81
Fixed carbon	50.88 to 67.08	46.86 to 52.48
Ash	22.29 to 32.16	9.26 to 21.84

that for some reason the pulverized coal was being blown out of the combustion chambers of the furnaces before it had been thoroughly consumed, was further substantiated by microscopic examination.

Determination of Explosion Pressures

The several samples of dust were also subjected to tests to determine the pressure which might be exerted by the dust in a possible explosion, as compared with

TABLE II. EXPLOSION PRESSURES DEVELOPED BY COAL DUST IN CLEMENT-FRASER APPARATUS

Sample	Volatile Matter, per Cent	Explosion Pressure, Lb. per Sq.In.
Pure coal dust	.....	14.5
Mill dust	23.54	10.21
Mill dust	20.6	8.7
Mill dust	15.91	4.6

pure pulverized coal; this test was conducted in the Clement-Fraser apparatus (described in Technical Paper 141 of the Bureau of Mines). Briefly, this apparatus consists of a glass globe, possibly 6 in. in diameter, containing a small platinum coil which is electrically heated. A sample of dust is blown against the heated coil and the pressure of the resulting explosion is recorded by a pressure indicator. In these tests about 0.003 oz. of pure pulverized coal was blown by about 8 cu.in. of oxygen under a pressure of 5½ in. of mercury against the platinum coil, which had been heated to a temperature of 2,200 deg. F. The average pressure obtained was 14.5 lb. per sq.in. The results of several tests on mill dust are given in Table II.

Further experiments to determine the explosibility of the mill dust were carried on in the dust explosion gallery of the Bureau. Tests were also made to determine the inflammability of the dust, one of these being the heating of a clay roasting dish 6 in. in diameter, in a furnace to a temperature of 2,000 deg. F. When the dish had reached this temperature, about one-sixth of an ounce of "mill dust" was quickly dropped in a cloud upon it. Another test was made by blowing a small amount of the dust in a cloud across the flame of a Meker burner.

These methods of testing were valuable, as they were almost identical with the conditions in and around a steel mill where the red hot iron and steel are often in close proximity to clouds of dust. The results obtained are summarized in Table III.

TABLE III. INFLAMMABILITY TESTS ON MILL DUST

Per Cent Volatile Matter in Sample	Observations
23.54, 20.60	Burned readily with more or less explosive violence.
15.91, 13.45, 11.5	Burned readily but without violence.
11.25, 10.99	Slightly inflammable.
7.17	Would not burn at all.

From the above-described tests and from similar tests with dust from the steel mills of other companies, it has been fairly well demonstrated that the division point between mill dust which will explode and that which will not explode is reached when the dust contains about 11 per cent of volatile matter.

Example of Fire Hazard

A good example of the great danger from mill dust, caused by the use of pulverized coal, is the fire which occurred a few years ago in a plant in which there were a number of puddling furnaces, some of which used pulverized coal as a fuel. A draft of air blew some of the coal dust over some red hot iron or slag. The dust immediately ignited and communicated the flames to the roof trusses. These were covered with fine dust which caused the roof to burn so quickly that the men barely escaped in safety from the building.

Stopping Fans Too Soon a Dangerous Practice

Many of the systems distributing coal dust to the furnaces consist fundamentally of fans which drive the dust from the storage bins through large pipes, from which small feed lines lead to the burners. It is the practice in some mills, when the furnaces are shut down, to stop the fan before all the pulverized coal in the pipe line has been thoroughly blown out. This is a rather dangerous practice, for the reason that, when the pressure from the fan is stopped, there is liable to be a back draft from the furnace which may take live sparks into the feed line. These sparks will smoulder until the fan is started again and then will be fanned into a

flame, igniting the dust in the feed line with a consequent explosion. The fatal explosion mentioned in the first part of this article was evidently caused thus.

Other Precautions to Be Taken

The roof trusses, pipes, platforms and all other places upon which any considerable amount of dust might accumulate should be kept thoroughly cleaned. In cleaning these trusses, platforms, and so on, no flame torches or open lights should be used, because of the danger of igniting any dust cloud which might be raised.

In some of the furnaces in which natural gas has been used, it is customary to keep both the gas and pulverized coal connections ready for service. If coal is being used, the gas connection should be cut out, as there is a chance that a leaky valve may allow gas to accumulate in the main coal feed and become ignited by a back fire from the furnace.

All electric switches and motors should be kept from dust and all electric wiring should be kept away from any place where dust in large quantities is liable to accumulate. As far as possible the wiring should be carried in conduits.

Protection Against Static Discharges

Provision should be made to protect properly all pulverizing machinery from damage which might be caused by an explosion due to the ignition of coal dust from static electricity in the machinery. All conduits, grinders and other parts in which an electric spark is liable to be produced should be grounded. Care should be taken that there is no way in which the coal dust can come in contact with hot metal, especially where pulverized coal storage bins are close to hot metal or hot slag.

Conclusion

The substitution of powdered coal for natural gas in the heating furnaces of the steel mills is of comparatively recent date, and there is hardly any doubt that the practice will become more general in its application as an adequate supply of natural gas becomes more difficult to obtain. As the problem of mill dust and the consequent danger therefrom seems to be prevalent in some plants using pulverized coal, it would seem imperative that every mill official should take precautions to prevent loss of life and property by an explosion or fire from this dust.

American Glass in Canada

Prior to the World War Canada's principal source of supply for plate glass was Great Britain, with Belgium second, the imports from the two countries in 1914 being 2,307,670 and 1,976,563 sq.ft. respectively, whereas during the fiscal year 1919 Canada obtained but 152,558 sq.ft. from Great Britain and none from Belgium. At present over 99 per cent of the glass imported into Canada comes from the United States, the quantity in 1919 being 1,736,895 sq.ft., whereas in 1914 only 299,042 sq.ft. came from that source.

Canada has been unable to secure its pre-war supply of plate glass, its total imports last year being but 1,889,451 sq.ft., against 4,672,534 in 1914, the reason being that the United States has become the world's chief source of supply, and was not in a position to meet the demand which was so suddenly made upon its manufacturers.

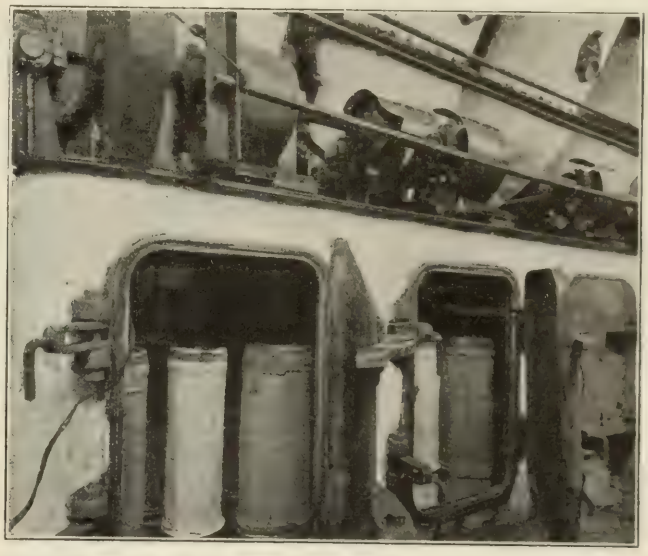
Canada has made some progress in the manufacture of plain window glass since the outbreak of the war.

Synopsis of Recent Chemical and Metallurgical Literature

Cleaning Blast-Furnace Gas.—A description of a dry method of cleaning iron blast-furnace gas previous to use in engines, stoves or boilers is given in *Iron and Coal Trades Review*, Dec. 19, 1919. Fifty-nine installations of this Halberg-Beth process are either in operation or under construction in Europe, with a total capacity of 174,000,000 cu.ft. per hr. (4,900,000 cu.m.), and it is claimed that the system overcomes the many difficulties in wet cleaning associated with providing and handling the very large amounts of water and power necessary.

Blast-furnace gas, after passing through an ordinary cyclone catcher for coarse dust, goes into a series of cooling towers, working like a surface condenser, and reducing its temperature to about 55 deg. C. From this it is taken to the filter bags by way of a preheater, where waste steam or gas superheats it about 10 deg. to prevent any moisture condensing during the next step.

The bag house is unique. One unit is divided into twelve sections, each containing twelve bags, fastened to a thimble floor as usual, and with closed tops suspended from a shaker frame. In operation, a suction fan draws clean gas through the fabric for about 7



TOP FLOOR OF FILTER HOUSE SHOWING SHAKING MECHANISM AND INSPECTION DOORS (OPEN) WITH FILTER BAGS IN POSITION

min., when the inlet and outlet valves for that section are reversed, placing pressure on the clean gas outside the bags. Hoops shown in the accompanying illustration prevent the bags from collapsing, the countercurrent of gas loosens dust in the fabric, and at the same time the upper suspension is vibrated up and down. In about 15 sec. the valves are reversed and a new cycle starts.

Gas at about 50 deg. C. is sent to burners or to gas engines. In the latter case it is cooled by sprays and then passes through a water separator. A content of 0.01 g. per cu.m. solid is easily attained in everyday working from dirty gas carrying 6 g., while 0.001 g. per cu.m. is often continuously attained. Filter bags last

at least six months, one year being a good average. One horse-power per 10,000 cu.ft. (280 cu.m.) gas per hr. is required to operate the fans, valves and shaking mechanism.

The Problem of Nitrogen.—The November-December issue of *Giornale di chimica Industriale* contains an important article by CARLO TONIOLO on the problem of nitrogen and its world and national importance. After describing the vital needs of nitrogen for the progress of civilized humanity, Mr. Toniolo dwells on the special need of Italy and gives comparative tables on capital required to produce nitrogen by the arc, cyanamide and synthesis of ammonia processes. These data, although specific to Italy, are of sufficient importance to be summarized in the accompanying Table IV.

Tables I and II show respectively the consumption of energy and of carbon in the nitrogen industries, and Table III shows the present status in Europe and North America of the potential and developed hydro-electric power.

TABLE I. CONSUMPTION OF ENERGY

Process	Kw.-Hr. per Kg. N	Kw.-Yr. per Ton N
Arc	70–75	8.4
Cyanamide	17–20	1.7–2.3
Synthesis of ammonia	1.5	0.17

TABLE II. CONSUMPTION OF CARBON

Process		Kg. per Kg. of N	Tons per Ton of N
Arc	For energy	51	51
Cyanamide	For reaction	3	3
	For energy	20	20
Total		23	23
Synthesis of ammonia	For reaction	3.6–3.8	3.6–3.8
	For energy	1.5	1.5
Total		5.2	5.2

TABLE III. POTENTIAL AND DEVELOPED HYDRO-ELECTRIC POWER

Country	Potential	Developed
United States	20,000,000	5,000,000
Canada	6,000,000	1,250,000
France	6,000,000	500,000
Norway	5,500,000	850,000
Spain	5,000,000	300,000
Italy	5,000,000	750,000
Sweden	5,000,000	600,000
Switzerland	1,500,000	400,000
Germany	1,000,000	500,000
Great Britain	700,000	60,000

He also describes the method developed by the Badische Anilin und Soda Fabrik at Oppau for the production of ammonium sulphate, ammonium chloride and urea based on the reactions:

$$CaSO_4 + CO_2 + H_2O + NH_3 = CaCO_3 + (NH_4)_2SO_4$$

$$2NaCl + CO_2 + H_2O + 2NH_3 = Na_2CO_3 + 2NH_4Cl$$

$$CO_2 + 2NH_3 = CO(NH_2)_2 + H_2O$$

Recent Chemical and Metallurgical Patents

British Patents

Complete specifications of any British patents may be obtained by remitting 25c. each to the Superintendent British Patent office, Southampton Buildings, Chancery Lane, London, England.

Purifying Graphite.—Graphite reduced to a state of fine subdivision is treated with an aqueous solution of hydrofluoric acid, with a strength of between 30 and 50 per cent, sufficient in quantity to form a mud so as to obviate the employment of an undue bulk of liquid. The strength of the acid to be used depends on the percentage of carbon desired in the purified product, since, in some cases, a high percentage is not necessary. For example, in the manufacture of pencils and parts of electro-technical apparatus, to remove the whole of the silica, the remainder is converted during the process of purification into a gelatinous form, available for use as an agglomerating agent in subsequent operations. (Br. Pat. 134,894—1919. E. RIDONI TURIN and SOC. TALCOE GRAFITI VAL CHISONE, Pinerolo, Italy; Jan 14, 1920.)

Treatment of Tungsten Ores.—Tungsten ores are mixed with carbon and heated in dry chlorine at about 300 deg. C. Tungsten chloride or oxychloride is volatilized and condensed. The condensed chloride can be transformed easily into tungstic acid or other tungsten compound. Alternately the tungsten ore may be reduced by heating with carbon to a red heat, after which chlorine is passed over. (Br. Pat. 134,891. IMPERIAL TRUST FOR THE ENCOURAGEMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH, Westminster, and O. J. STANNARD, London; Jan. 14, 1920.)

Cementation.—Machined articles of soft iron and mild steel are coated with a metal such as nickel or cobalt and then subjected to a temperature of 1,000 to 1,200 deg. C. while protected from oxidation by a deposit or by a packing, until the nickel, etc., are absorbed by the iron or steel. Chromium and vanadium may also be used as the coating metal if the deposit thereof be protected by a deposit of iron or nickel. The packing material may be inert to the metal, or may act as a carburizer. (Br. Pat. 134,864—1919. E. H. JONES, London; Jan. 14, 1920.)

Recovering Lead and Tin.—Lead and tin are recovered from materials containing them, in the case of lead, with a treatment of hot ferric chloride solution, and in the case of tin, with hot ferric chloride or ferric sulphate solution. To the resulting solution, substan-

TABLE IV. CAPITAL INVESTMENT IN NITROGEN PLANTS

Process	Product	Required Capital Invested per Ton of Nitrogen		Cost of Production of 1 Kg. of Fixed Nitrogen with a Cost per Kw.-Yr. of		
		Thermo-electric Energy	Hydro-electric Energy	$20	$15	$10
Arc	Basic calcium nitrate with about 13 per cent N	$890	$1800	$0.32	$0.29	$0.25
Cyanamide	Calcium cyanamide with 18-20 per cent N	293	545	$0.16–$0.22	$0.15–$0.21	$0.14–$0.20
Synthesis of ammonia	Ammonium sulphate with 20-21 per cent N	$513		With a cost per ton of coal of $4, and per ton of lignite of $2.50. $0.15		
	Ammonium chloride with 20-24 per cent N	$400–$600		.12		

Ammonia from coal distillation, market price per kg, $0.33@$0.35.
Chilean nitrate, market price per kg., $0.32@$0.34.

tially free from acid, there is added about one-third of its volume of concentrated ferrous chloride or ferrous sulphate solution, and the lead or tin is then precipitated by means of scrap iron. The deposition is preferably carried out by adding from time to time successive portions of solution to be treated to solutions from which the metal has already been deposited. (Br. Pat. 135,052—1919. W. G. RUMBOLD, London; Jan. 14, 1920.)

Potassium Chloride.—Potassium salts are recovered from blast-furnace slag by the addition of calcium chloride to the slag, in a molten state, and by collecting the volatilized potassium chloride formed. The calcium chloride is introduced from a hopper into the stream of molten slag as this flows from the furnace to the ladle. Intimate mixing takes place by having the slag flow down a cascade into a chamber from which the potassium chloride fumes escape into a condenser, where they meet a spray of water and the potassium chloride solution is collected for further use. The treated slag is said to be improved for the making of slag cement. (Br. Pat. 134,665—1919. E. BURY, O. OLANDER, T. SMITH and F. BAMBRIDGE, all of Salturn-by-the-Sea, Yorkshire; Jan. 7, 1920.)

Magnesium Sulphate.—Magnesium sulphate is produced by heating to dull red a mixture of a magnesium-containing compound or mineral and calcium sulphide in a stream of air, water vapor and carbon dioxide. The separation of the resulting mixture of magnesium sulphate and calcium carbonate is effected by lixiviation. If the raw materials contain magnesium carbonate, the use of carbon dioxide can be dispensed with. (Br. Pat. 134,884. E. E. and P. C. DUTT, Jubbulpore, India; Jan. 14, 1920.)

Personal

Colonel WILDER D. BANCROFT, chairman of the division of chemistry, National Research Council, recently delivered a lecture at Oberlin College on colloid chemistry, and Mr. MARSH of the Hercules Powder Co. followed in the same alumni course with a lecture on high explosives.

Dr. ALLERTON S. CUSHMAN will deliver the 1920 course of lectures on "Chemistry and Civilization" under the Richard B. Westbrook Foundation at the Wagner Institute. Four lectures will be given on successive Saturday evenings, beginning March 13, at the hall of the Wagner Free Institute of Science, 17th Street and Montgomery Ave., Washington, D. C. Lectures are free to all.

J. R. DAWSON, formerly metallurgist with the American Steel & Wire Co., Worcester, Mass., has been appointed instructor in the department of metallurgy, Lehigh University, Bethlehem, Pa.

D. FRANKLIN FISHER, formerly of the U. S. Bureau of Chemistry, stationed at New York, has become research chemist for the Van Camp Packing Co., Indianapolis, Ind.

Prof. H. G. GREENISH, dean of the School of Pharmacy of the Pharmaceutical Society, London, has had conferred on him an honorary doctorate by the University of Paris.

FRANKLIN K. LANE, who retired as Secretary of the Interior on March 1, is now vice-president and legal adviser of the Mexican Petroleum Co. and the Pan-American Petroleum & Transport Co.

Dr. GRAHAM LUSK, professor of biological chemistry at Cornell Medical College, New York; Dr. LAFAYETTE B. MENDEL of Yale University, New Haven, Conn., and E. V. MCCOLLUM of Johns Hopkins University, Baltimore, Md., have been elected associate members of the Société Royale des Sciences Médicales et Naturelles de Bruxelles.

FRANK MERRICKS has been elected president of the London Institution of Mining and Metallurgy for 1920.

W. H. NICHOLS, president of the General Chemical Co., New York, has had conferred on him the degree of doctor of chemistry by the University of Pittsburgh.

Dr. A. A. NOYES has resigned from the Massachusetts Institute of Technology, to become director of chemical research at the California Institute of Technology, Pasadena, Cal.

W. A. NOYES, director of the department of chemistry of the University of Illinois, Urbana, Ill., has had conferred on him the degree of doctor of chemistry by the University of Pittsburgh.

F. K. OVITZ, superintendent of the Seattle Station, U. S. Bureau of Mines, has resigned to accept a position as fuel efficiency engineer with the Standard Oil Co. He will be located at Whiting, Ind.

G. A. RANKIN, who was with the Chemical Warfare Service at American University, has recently been made research chemist with the Geophysical Laboratory, Carnegie Institution, Washington, D. C.

F. H. RIDDLE, formerly with the Bureau of Standards at Pittsburgh, has accepted the position of director of research with the Jeffrey-Dewitt Co., Detroit, Mich.

Dr. R. E. RINDFUSZ, formerly assistant in chemistry at Oberlin College, has been appointed chief chemist to the American Writing Paper Co., at Holyoke, Mass.

Dr. WILLIAM T. SEDGWICK, head of the department of biology and public health at the Massachusetts Institute of Technology, will be the first exchange professor with the Universities of Cambridge and Leeds.

H. E. SKOUGOR has severed his connection with Guggenheim Bros., the Chile Exploration Co. and the Braden Copper Co. and has opened an office at 120 Broadway, as consulting industrial engineer.

EUGENE STEBINGER has been appointed chief of the foreign section of the Mineral Resources Branch of the U. S. Geological Survey. He has lately returned from private work in the Tampico oil fields of Mexico.

Dr. ALLEN E. STERN of the department of chemistry of the University of Illinois has resigned to become head of the division of physical chemistry at the University of West Virginia.

Dr. VICTOR C. VAUGHAN of the University of Michigan, Ann Arbor, presented a paper on Jan. 30 before the Institute of Medicine at Chicago on "The Chemistry of the Protein Molecule in Relation to Infection."

C. ERB WUENSCH, secretary of the Alumni Association of the Colorado School of Mines, has been in New York and other Eastern cities on professional business.

The American Physical Society elected the following officers at its St. Louis meeting: President, J. S. Ames; vice-president, Theodore Lyman; secretary, D. C. Miller; treasurer, G. B. Pegram; managing editor, F. Bedell; councillors, F. B. Jewett and Max Mason; members of the editorial board, E. L. Nichols, C. M. Sparrow and W. F. G. Swann.

The Southeast Texas Section of the American Chemical Society announces the election of the following officers for the year 1920: President, Dr. Felix Paquin, Galveston; vice-president, H. B. Weiser, Houston; councillor, Dr. F. W. Bushong, Port Arthur; treasurer, H. D. Draper, Houston; secretary, P. S. Tilson, Houston.

Obituary

WILLIAM J. DWYER, who established the Trade News Service, New York, died at his home in New Rochelle, N. Y., Feb. 19. Prior to entering the field on his own account, Mr. Dwyer was a member of the reportorial staff of the *Oil, Paint and Drug Reporter.*

JAMES GAYLEY, formerly vice-president of the United States Steel Corp., adviser of Andrew Carnegie in the creation of the Carnegie libraries and other Carnegie institutions presented to the public, died on Feb. 25 in his home, 555 Park Ave., New York City, after a brief illness. Mr. Gayley was sixty-five years old.

Perhaps no other individual in the world did more toward the perfection of the blast furnace than did Mr. Gayley. He had an international reputation as an inventor of steel- and iron-making apparatus; and especially did he achieve fame as the creator of the dry air blast, a refrigeration method of extracting the moisture from the blast-furnace atmosphere.

He also invented the auxiliary casting stand now used extensively in bessemer steel plants. He received the Elliot Cresson medal from Franklin Institute, Philadelphia, for inventing the dry air blast, and had been honored by many colleges and scientific institutions in the country for his achievements in the iron and steel industry.

Mr. Gayley was from his very entry into the steel-making business an intimate friend and adviser of Andrew Carnegie. He was one of the original Carnegie partners, "one of the boys who made the name Carnegie famous," as the Laird of Skibo used to say.

Mr. Gayley was born in Lock Haven, Pa., Oct. 11, 1855, a son of Rev. Dr. Samuel Alexander Gayley and Agnes G. Malcolm Gayley. After attending the public school at Lock Haven, he entered Lafayette College, where he was graduated with the engineering class of 1876, taking honors in mining and metallurgy. His first position was as chemist of the Crane Iron Co., the oldest iron-making concern in the Lehigh Valley. It was from the machine shops of the Crane Iron Co. that Captain William R. Jones, whose services to the steel industry while manager of the Edgar Thomson Steel Works ever will be remembered, graduated. Three years later Mr. Gayley became superintendent of the Missouri Furnace Co. of St. Louis. Shortly afterward he accepted the position as superintendent of furnaces at the E. & G. Brooks Iron Co., at Birdsboro, Pa.

In the fall of 1885, at the invitation of Captain Jones, Mr. Gayley accepted the position of furnace superintendent of the Edgar Thomson Steel Works at Braddock. This was the beginning of his association with Andrew Carnegie.

When Charles M. Schwab was transferred to the Homestead Steel Works Mr. Gayley was appointed general superintendent of the Edgar Thomson works, and in 1895 was transferred to the general offices in Pittsburgh to assist the late Henry M. Curry in the increasing business of the ore department. Upon the retirement of Mr. Curry from active business Mr. Gayley succeeded to the management of the ore department and also as a member of the board of managers of the Carnegie Steel Company, Ltd.

He continued with the Carnegie interests until the formation of the United States Steel Corp. in 1901, when he was made first vice-president of the Steel Corp., and had since made his headquarters in New York City. He retired from the Steel Corp. about eight years ago to devote his undivided attention to his personal interests. He was succeeded in the corporation by D. G. Kerr.

Mr. Gayley was generous toward Lafayette College. He had given approximately $100,000 to that institution, among his gifts being a splendid chemical and metallurgical laboratory.

Mr. Gayley for many years was president and director of the American Ore Reclamation Co. He was a trustee of Lafayette College, Tome Institute, was at one time president of the board of directors of the American Institute of Mining Engineers, and was a member of the Iron and Steel Institute of Great Britain. He was a member of the following clubs: Duquesne, Metropolitan, University, Engineers, Oakland, Golf, Bankers, Automobile of America and the Society of St. Andrew's and the Pilgrims of the United States.

Dr. S. MACKAY, professor of chemistry at Dalhouse University, died of pneumonia at Halifax, N. S., on Jan. 6. He was born in Nova Scotia in 1864.

JAMES P. REILLY of The Barrett Co., New York, died recently at his home at Germantown, Pa. Death was caused from hemorrhage of the brain from an attack which occurred two weeks before his death and which, it is believed, is traceable to overwork during the war when he was chairman of a chemical board, with headquarters in Washington. Prior to his last illness, Mr. Reilly had never known a sick day in his life. He was born in Ireland forty-three years ago, and was educated in England. As a youth he came to Philadelphia. He had been connected with The Barrett Co. for many years. He leaves a widow, Mrs. Minnie McKey Reilly, a daughter and three sons.

Dr. EDWIN A. STRONG, professor emeritus of physics at the Michigan State Normal College, died Feb. 4 at the age of eighty-six.

RALSTON C. WARE, president of Ware Bros. Co., Philadelphia, publishers of *American Fertilizer* and other trade journals, was stricken with pneumonia and died Wednesday, Feb. 4, at the age of sixty.

HERBERT SPENCER WOODS, professor of biological chemistry at the University of Texas, died at Dallas on Jan. 4, following an operation. He was thirty-six years of age.

Current Market Reports

The Non-Ferrous Metal Market

New York, March 1.—There has been little change since last week's report. Tin, lead and mercury advanced, while zinc and silver declined slightly.

		Cents per Lb.
Copper, electrolytic		19.00
Aluminum, 98 to 99 per cent		33.00
Antimony, wholesale lots		12.00
Nickel, ordinary		43.00
Nickel, electrolytic		45.00
Tin, Straits, spot		64.50
Lead, New York, spot		9.00
Lead, E. St. Louis, spot		8.37½
Zinc, spot, New York		9.30
Zinc, spot, E. St. Louis		9.00
Silver	oz.	$1.29½
Cadmium	lb.	1.50
Cobalt	lb.	1.50
Platinum	oz.	150.00
Iridium	oz.	250.00
Palladium	oz.	150.00

Chemical and Allied Industrial Markets

New York, February 27, 1920.

Continued firmness characterized the chemical market during the past week, there being but few changes of importance. Demand in the spot market is still brisk and small supplies are the only drawback. Unfavorable rate of exchange has slightly affected exporting in some lines, but *caustic soda* still tops the list and is under heavy foreign inquiry.

HEAVY CHEMICALS

White salammoniac remains steady, with a slight upward tendency, 15@16c. per lb. being the listing on carlots, while in less than carlots it is quoted at 16@18c. *Barium chloride* has been very active and quotations vary greatly, $100 per ton being the lowest and $130 the highest. There is very little of this material on the spot market and producers

are pushed to the limit to meet their contracts. The export demand has fallen off slightly on *caustic potash*, while domestic demand continues firm. The last price of 28@32c. is still maintained.

Soda ash is practically off the spot market. Sales have been reported on the light at $2.50@$2.60 per cwt., while $2.70@$2.75 is being asked for the dense. Foreign demand remains unaltered despite the low rate of exchange. *Cobalt oxide* has been advanced from $1.50@$1.55 per lb. to $2@$2.05. This change went into effect the early part of last week. *Niter cake* is very scarce and the price still remains firm at $7.@$7.50 per ton. There has been a tightening in *sal soda* during the past week, with the price of $1.35@$1.40 per cwt. remaining firm. *Oxalic*, crystals, has advanced during the past week and as high as 46c. per lb. is being asked for spot material, but the average price ranges from 40@42c. per lb. A slight tightening of supplies has been felt in *sulphuric*, 66 deg., which remains firm at $22 per ton.

Coal-Tar Products

The coal-tar products market remains practically unchanged, although it is reported that producers are not being pushed as hard as they were a few weeks ago, but as yet this has not affected the spot market. *Dimethylaniline* continues scarce owing to the lack of methyl alcohol. Quotations range from 95c.@$1.20 per lb. *H acid* is practically unobtainable either on spot or contracts. The price of $1.60@$1.75 per lb. remains firm. *Pthalic anhydride* has picked up slightly and is now being offered at 60@70c. per lb. The spot market on *benzol* is rather tight. Producers are supplying contract orders at 25c. per gal. *Alpha naphthol* continues scarce, there being very little material available on spot. Crude is quoted at $1@$1.10 per lb., while refined is listed at $1.40@$1.60 per lb.

Naval Stores

There has been a gradual decline in this market lately, due principally to the unfavorable rate of exchange. England has fallen below her previous large buying business in this country. The coming spring painting campaign is expected to put *turpentine* back in its recently high position. Present quotation on spirits of turpentine is about $1.93 per gal., as compared with $2.05 a few weeks ago. *Rosins* have dropped in all grades due to a falling off of foreign inquiry.

Crude Rubber

Evidently the bottom has not been reached in the crude rubber market, as prices continue steadily on the decline. Buyers are anticipating a still lower level and are not very active beyond their actual present needs. The continued low rate of exchange is responsible for the low price level now existing in this market.

Oils

An easier market in practically all lines in oils is the report of the past week. *Cottonseed* continues on the decline and is quoted as low as 18¼c. per lb. *Soya bean* remains quiet with a slight drop from 17¾c. to 16¾c. per lb. *Linseed* has been firmly maintained and it is pointed out by some that a drop in this item will occur before the spring buying season opens.

Miscellaneous Materials

The future market in *barytes* is still indefinite as to price. Producers' quotations are from month to month. Demand on this item remains brisk and plants are being worked to their limit in order to meet contracts. The present quotation holds firm at $35@$40 per ton. Quotations on *feldspar* are still nominal at $13.50@$18 per ton with great difficulty in locating any material even at the latter price.

Chicago, February 25, 1920.

Strong markets in all lines prevail, with production apparently not able to keep up with demand. Pressure of export business continues on alkilis, and prices in these items have been forced up another notch. Actual trading is light in all lines except alkalis, apparently because consumers refuse to buy anything beyond current needs.

Heavy Chemicals

Methyl alcohol is almost unobtainable, offers ranging from $2.25@$2.50 per gal. for 95 per cent grade. Owing to scarcity of the product, actual sales are few and for small quantities. *Ethyl* grade seems to be a little freer, some business being done at $5.35@$5.70 for 190 proof, in bbl. Production is so far behind spot demand that no orders for later delivery are being taken. *Formaldehyde* remains firm at 48@50c., with the severe shortage formerly noted still effective, with practically no future delivery contracts being placed.

On continued Eastern demand for export shipment *caustic soda* is again up, price for the solid being around $4.25 per cwt. in cars, f.o.b. works, and for the granulated $4.50@$4.75, with the latter figure ruling today. These figures represent an advance of from 35@50c. per cwt. since last reported. *Bleaching powder* remains stationary at $3 per cwt., f.o.b. works, in carload lots. Similar conditions have pushed the price of *soda ash* up 15c., with today's quotation $2.25 per cwt. Accurate quotations on *sodium bichromate* are impossible, transactions in small quantities having been closed during the past two weeks at 35@45c. per lb. It is offered today at 40c.

Acids show no important change. Demand is light, but production is so nearly completely under contract as to preclude any drop in prices. Current quotations are: *Sulphuric*, 66 deg., $22 per ton in cars; *muriatic*, 22 deg., $2.50@$2.62½ per cwt.; *nitric*, 42 deg., $7.25 per cwt., and *oxalic*, 40@42c. per lb. in bbl.

Coal-Tar Products

This market remains firm in all lines, producers holding the current high figures and buyers reluctant to do much trading. As production is gradually getting better, it seems that somewhat lower prices may soon prevail. *Benzol* and *toluol* stand at 27c. and 28c. respectively in large quantities from refiners. Spot business is very light and is at a slight advance over these quotations. In the acids no change is noted, *picric* being quoted at 25c. per lb., *benzoic* at 75c. for technical grade and *salicylic* at 44c. for technical grade. *Aniline oil* at 34c. and *aniline salts* at 44c. show no change, supply being very light and but little demand being felt at these high prices.

Vegetable Oils

Quietness prevails throughout this line, no changes of moment having occurred for some time. Current quotations for *linseed oil* in bbl. are $1.98 per gal., in cars, $1.75@$1.80 per gal.; *cocoanut oil*, miller grade, in bbl., 19c. per lb.; *soya bean oil*, 18@19c. in bbl.; *corn oil*, prime, in tanks, 19@20c.; *cottonseed oil*, crude, in bbl., 18¾c., prime summer yellow, in bbl., 23@23½c. These quotations are all f.o.b. Chicago.

Flotation Oils; Naval Stores

Foreign demand for *turpentine* has ceased for the present, and the domestic trade seems unwilling to pay such high prices, hence price is off from a quotation of $2.16 per gal. a few days ago to $1.96 per gal. today. With the new crop an unknown quantity, trading is apt to remain light. Acute shortage keeps pine oil up to its previous high mark of $1.50 for both pure and destructively distilled. Conditions affecting *turpentine* also prevail in trading in *rosin* as a result of which prices have receded. Present quotation on *F* grade is $18.80 and on *WW* is $22@$22.50.

Fertilizers

There is no change in prices in this market. As buyers seem to feel that conditions justify their expectation of lower prices soon, but little actual trading is being done. Last quotations were: *Ground blood*, $8; *unground blood*, $7.80; high-grade *ground tankage*, $7.65; *bone meal*, in carloads, f.o.b. Chicago, $46.50 per ton.

The Iron and Steel Market

Pittsburgh, February 28, 1920.

The iron and steel market has been the subject of conflicting emotions. While it may be the case sometimes that the market is controlled by actual physical conditions as to supplies and requirements, it has not infrequently been the case that the actual market has been dictated largely by men's feelings or emotions. In times of relatively slack demand for steel the consumer has underrated his prospective requirements and has had an undue feeling of security about the certainty of prompt deliveries in future, while in times of slight scarcity he has frequently been unduly alarmed and has sought to buy in excess of his real requirements.

Set in juxtaposition, two incidents of the past week are illustrative of the psychological aspect of the market just referred to. About three weeks ago sheet bars sold at the new record high price of $65, the buyers being automobile interests intending to have the bars converted into sheets under conversion contracts at sheet mills. Such conversion contracts have been easy to make with some sheet mills, on account of their being short of steel and thus having idle rolling-mill capacity. Even the Steel Corporation subsidiary has been quite ready to make such contracts in some cases, at quite moderate charge for the conversion. Last week sheet bars similarly brought $70. This week there were two sales, one of 1,000 tons of open-hearth at $80, and another of 1,500 tons of bessemer at $75. The item to be set in opposition to this feverish buying at sharply advancing prices is that a pig-iron producer has just sold a round tonnage of basic pig iron for early delivery on the basis of $41.50, valley, when previously the market had been pushed up by actual purchases to $43 and for a time had been well established at that figure as minimum for any delivery.

Market Abandoning Runaway Disposition

Further illustrating the market's tendency to abandon its disposition toward a runaway, either through discovery of an inability in the market to run very fast or far, or from an accretion of conservatism dictated by sober second thought on the part of producers, it is to be related that several large independents, hitherto practically out of the market, have set relatively moderate prices at which they will cover their customers for second quarter delivery, these prices being 3c. and 3.10c. for bars and shapes respectively, $2 a ton above the war control prices and $13 a ton above the March 21 or Industrial Board prices, still rigidly adhered to by the Steel Corporation, and 3.25c. to 3.50c. for plates, comparing with 3.25c. under the war control price and 2.65c. by the March 21 schedule.

It should be particularly noted that these prices are set for settlement of second quarter deliveries, because curious statements have been appearing in the financial press to the effect that the independent steel producers are sold up far ahead, hence "rumors from Pittsburgh" that the steel market is less strong than had been imagined do not mean anything. Nothing could be further from the truth than to assert that the independents at this time are unusually well sold up. On the contrary, they have unusually light order books, for a period of apparently heavy demand. This arises from the fact that the class of mills that have been seeking fancy prices could obtain them only for early deliveries while those who pursued the pseudo-conservative policy of staying out of the market and not naming prices at all have naturally not been making sales. They have by promise to customers reserved large tonnages to be furnished at prices to be named later, some of these prices having been named in the past few days, as related above, but such operations constitute an obligation on the part of sellers, not an obligation on the part of buyers.

Revolt Against Automobile Steel Price Dictation

A feature of the general steel market situation is the growing revolt among steel consumers against automobile trade dictation of prices. The automobile trade has been bidding fancier and fancier prices for prompt lots of steel products, as well as for various other materials, including lumber, plate glass, etc., and buyers of such commodities find that the pace set is one that simply cannot be followed by the manufacturers of such commonplace articles as agricultural implements, hardware, freight cars and locomotives. There is a growing disposition to reflect that the automobile trade, no matter how much money it may perhaps have at its disposal, does not and cannot consume the bulk of the production in any important commodity. In steel, for instance, while its consumption has not been estimated closely, the quantity can hardly be a quarter million gross tons of finished rolled steel a month, while the steel industry's capacity is in excess of three million gross tons a month.

Transportation Conditions Unimproved

On the whole transportation conditions as affecting the iron and steel industry have not improved. Coal operators claim their car shortage is greater than ever. Car supplies in the Connellsville region have been better this week than last, but were poorer last week than the average of several weeks preceding. On a general average the supply of cars for moving finished steel from mill may have improved somewhat. One very favorable item is that the Carnegie Steel Co., which four weeks ago had between 150,000 and 160,000 tons piled at its various plants awaiting shipment, has now cut the accumulation in half. On the other hand, the American Sheet & Tin Plate Co.'s accumulation has grown until it amounts to about 50,000 tons, or approximately ten days of normal production. A third aspect is presented by another subsidiary of the Steel Corporation, the National Tube Co., which has operated at fully 90 per cent of capacity since the first of the year, and has been able to ship its product as fast as made.

From these and other considerations a generalization may be hazarded that car shortages are a local matter, depending chiefly upon the terminal and other facilities in various districts. From this, furthermore, it may be inferred, as many railroad men have asserted, that what the railroads need is not so much cars and locomotives as additional terminal and siding facilities, and probably more block signalling. There is, however, a moderate volume of freight car inquiry in the market, and buying in the next few months may aggregate several tens of thousands of cars. Assertions sometimes encountered setting immediate railroad needs in terms of hundreds of thousands of cars may well be ignored.

Pig Iron

As noted above, basic pig iron has sold at $41.50, valley basis, against a previously established market of $43. Bessemer remains at $42, valley, and can easily be had for prompt shipment at this figure. Foundry remains at $42, valley, for extended delivery, with doubt whether much premium would have to be paid for prompt. Throughout the local market inquiry is very light, and some recent purchases were of smaller tonnages than the buyers originally contemplated.

Steel

Sheet bars have sold at up to $80, as reported above, and it is uncertain at what prices mills will cover regular customers for additional tonnages. Billets have been in light demand and correspondingly light supply, being quotable perhaps at $55 to $60.

Ferro-Alloys

There seems to be a scarcity of prompt ferromanganese, with sales of small lots reported at over $200. Furnaces continue to quote $160, delivered, for second half, but it is possible this might be shaded to $150. English is about $150, c.i.f. Spiegeleisen is held at $57 to $60, furnace, for futures.

Electrolytic ferrosilicon, 50 per cent, remains at $80, delivered, but one or two makers have just advanced to $85, while 75 per cent remains at $140, delivered. Bessemer ferrosilicon remains at last week's price of $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, f.o.b. Jackson, Ohio.

Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 – .....
Sulphur chloride	lb.	.05½ –	.06 – .....
Sulphur, crude	ton	22.00 –	..... – .....
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½ –	.46 – .50
Tin oxide	lb.	.50 – .60	.65 – .....
Zinc carbonate, precipitate	lb.	..... –	.20 – .....
Zinc chloride, gran	lb.	.13 –	.13½ – .15
Zinc cyanide	lb.	.49 –	.50 – .....
Zinc dust	lb.	.11½ – .12½	.13 – .15
Zinc oxide, dry American	lb.	..... –	.09½ – .12
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 — $1.10
Alpha naphthol, refined	lb.	1.40 — 1.60
Alpha naphthylamine	lb.	.40 — .50
Aniline oil, drums extra	lb.	.34 — .45
Aniline salts	lb.	.42 — .50
Anthracine, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde (f.f.c.)	lb.	2.00 — 2.10
Benzidine, base	lb.	1.05 — 1.25
Benzidine, sulphate	lb.	.90 — 1.00
Benzoic acid, U.S.P.	lb.	.90 — 1.10
Benzoate of soda, U.S.P.	lb.	.80 — 1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 — .36
Benzol, 90%, in drums (100 lb.)	gal.	.25 — .29
Benzyl chloride, 95-97%, refined	lb.	.35 — .40
Benzyl chloride, tech	lb.	.25 — .35
Beta naphthol benzoate	lb.	.50 — .55
Beta naphthol, sublimed	lb.	.65 — .80
Beta naphthol, tech	lb.	.45 — .55
Beta naphthylamine, sublimed	lb.	2.25 — 2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 — 1.10
Cresylic acid, 95-97%, dark, in drums	gal	.85 — 1.00
Cresylic acid, 50%, first quality, drums	gal.	.60 — .70
Dichlorbenzol	lb.	.07 — .10
Diethylaniline	lb.	1.40 — 1.50
Dimethylaniline	lb.	.95 — 1.20
Dinitrobenzol	lb	.26 — .37
Dinitroclorbenzol	lb	.25 — .30
Dinitronaphthaline	lb	.45 — .55
Dinitrophenol	lb.	.32 — .36
Dinitrotoluol	lb.	.38 — .45
Dip oil, 25%, tar acids, car lots, in drums	gal	.38 — .40
Diphenylamine	lb.	.55 — .65
H-acid	lb	1.60 — 1.75
Metaphenylenediamine	lb	1.15 — 1.80
Monochlorbenzol	lb	.12 — .15
Monoethylaniline	lb	1.50 — 1.75
Naphthaline crushed, in bbls. (250 lb.)	lb	.06 — .08
Naphthaline, flake	lb.	.07 — .08
Naphthaline, balls	lb	.08½ — .10
Naphthionic acid, crude	lb	.75 — 1.25
Nitrobenzol	lb	.14 — .19
Nitro-naphthaline	lb	.30 — .35
Nitro-toluol	lb	.20 — .30
Ortho-amidophenol	lb	3.75 — 4.25
Ortho-dichlor-benzol	lb	.15 — .20
Ortho-nitro-phenol	lb	.80 — 1.25
Ortho-nitro-toluol	lb	.25 — .40
Ortho-tolnidine	lb	.25 — .45
Para-amidophenol, base	lb	2.50 — 3.50
Para-amidophenol, HCl	lb	2.50 — 3.25
Para-dichlor-benzol	lb	.12 — .18
Paranitraniline	lb	1.00 — 1.35
Para-nitro-toluol	lb	1.35 — 1.50
Paraphenylenediamine	lb	2.15 — 3.00
Paratoluidine	lb	1.75 — 2.50
Phthalic anhydride	lb	.60 — .70
Phenol, U. S. P., drums (dest.), (240 lb.)	lb	.12 — .25
Pyridin	gal	2.00 — 2.50
Resorcin, technical	lb	3.75 — 4.50
Resorcin, pure	lb	6.50 — 6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb	.43 — .45
Salicylic acid, U. S. P.	lb.	.55 — .60
Salol	lb	.90 — .95

Solvent naphtha, water-white, in drums, 100 gal..	gal.	$0.22	—	$0.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.25	—	.30
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	....
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	....
Xylol, commercial, in drums, 100 gal	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42	—	$0.45
Beeswax, refined, yellow	lb.	.47	—	.48
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1	lb.	.80	—	.88
Carnauba, No. 2, regular	lb.	.65	—	.78
Carnauba, No. 3, North Country	lb.	.46	—	.48
Japan	lb.	.18½	—	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.....	—	.07½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	—	.07½
Paraffine waxes, refined, 118-120 m.p.	lb.	.....	—	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½	—	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	.....	—	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	.....	—	.14
Stearic acid, single pressed	lb.	.23	—	.26
Stearic acid, double pressed	lb.	.28	—	.29
Stearic acid, triple pressed	lb.	.32	—	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.48
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.60
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl	280 lb.	$17.00	—	$18.50
Rosin E-I	280 lb.	18.05	—	18.75
Rosin K-N	280 lb.	18.50	—	21.50
Rosin W. G.-W. W	280 lb.	21.50	—	24.25
Wood rosin, bbl	280 lb.	15.50	—	17.50
Spirits of turpentine	gal.	.....	—	1.93
Wood turpentine, steam dist	gal.	.....	—	1.93
Wood turpentine, dest. dist	gal.	.....	—	1.85
Pine tar pitch, bbl	200 lb.	8.50	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	14.75
Retort tar, bbl	500 lb.	15.00	—	15.25
Rosin oil, first run	gal.	.93	—	.95
Rosin oil, second run	gal.	.96	—	.97
Rosin oil, third run	gal.	1.10	—	1.15
Rosin oil, fourth run	gal.	.....	—	1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.42½	—	$0.44
Upriver coarse	lb.	.31½	—	.35
Upriver caucho ball	lb.	.31½	—	.34½
Plantation—First latex crepe	lb.	.46½	—	.49
Ribbed smoked sheets	lb.	.46	—	.48
Brown crepe, thin, clean	lb.	.41	—	.43
Amber crepe No. 1	lb.	.45	—	....

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.18	—	$0.19
Castor oil, AA, in bbls	lb.	.21¼	—	.23
China wood oil, in bbls	lb.	.23½	—	.25¼
Cocoanut oil, Ceylon grade, in bbls	lb.	.18½	—	.19½
Cocoanut oil, Cochin grade, in bbls	lb.	.20½	—	.23
Corn oil, crude, in bbls	lb.	.19	—	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.18¼	—	.20
Cottonseed oil, summer yellow	lb.	.22	—	.27
Cottonseed oil, winter yellow	lb.	.24½	—	.25½
Linseed oil, raw, car lots	gal.	1.65	—	1.68
Linseed oil, raw, tank cars	gal.	1.60	—	1.62
Linseed oil, boiled, car lots	gal.	1.70	—	1.75
Olive oil, commercial	gal.	2.50	—	3.00
Palm, Lagos	lb.	.16½	—	.16½
Palm, bright red	lb.	.15½	—	.17½
Palm, Niger	lb.	.16	—	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.22½	—	.24
Peanut oil, refined, in bbls	lb.	.27	—	.28
Rapeseed oil, refined in bbls	gal	1.45	—	1.68
Rapeseed oil, blown, in bbls	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.18½	—	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.16½	—	.20

FISH

Winter pressed Menhaden	gal.	$1.20	—	....
Yellow bleached Menhaden	gal.	1.18	—	....
White bleached Menhaden	gal.	1.20	—	....
Blown Menhaden	gal.	1.26	—	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00	—	$40.00
Barytes, off color	ton	20.00	—	25.00
Blanc fixe, dry	lb.	.04½	—	.05½
Blanc fixe, pulp	ton	30.00	—	50.00
Casein	lb.	.16	—	.18
Chalk, English, extra light	lb	.05	—	.07
Chalk, English, light	lb.	.04½	—	.06
Chalk, English, dense	lb.	.04	—	.05
China clay (Kaolin), imported, lump	ton	25.00	—	35.00
China clay (Kaolin), imported, powdered	ton	30.00	—	60.00
China clay (Kaolin), domestic, lump	ton	10.00	—	20.00
China clay (Kaolin), domestic, powdered	ton	25.00	—	40.00
Feldspar	ton	13.50	—	18.00
Fluor spar, acid grade, lump, f.o.b. mines	net ton	30.00	—	45.00
Fluor spar, acid grade, ground, f.o.b. mines	net ton	50.00	—	52.00
Fuller's earth, domestic, powdered	ton	25.00	—	30.00
Fuller's earth, imported, powdered	ton	35.00	—	40.00
Graphite, crucible, 85% carbon content	lb.	.....	—	07½
Graphite, crucible, 86% carbon content	lb.	.....	—	07
Graphite, crucible, 87% carbon content	lb.	.....	—	.07
Graphite, crucible, 88% carbon content	lb.	.....	—	.08
Graphite, crucible, 89% carbon content	lb.	.....	—	.08½
Graphite, crucible, 90% carbon content	lb.	.....	—	.08½
Graphite, crucible, 91% carbon content	lb.	.....	—	.08½
Graphite, crucible, 92% carbon content	lb.	.....	—	.09
Graphite, crucible, plus 92%	lb.	.....	—	.12
Pumice stone, imported	lb.	.03	—	.06
Pumice stone, domestic	lb.	.02½	—	....
Shellac, orange, fine	nominal lb.	1.55	—	1.60
Shellac, orange, superfine	lb.	1.65	—	1.70
Shellac, A. C. garnet	lb.	1.30	—	1.35
Soapstone	ton	15.00	—	25.00
Talc, domestic	ton	16.00	—	60.00
Talc, imported	ton	60.00	—	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	75-80 at Chester, Penn
Chrome cement	net ton	45-50 at Chester, Penn
Clay brick, 1st quality fireclay	1,000	38-45 at Clearfield, Penn
Clay brick, 2nd quality	1,000	33-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn
Silica brick	1,000	45-50 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20	—	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21	—	.50
Ferro-manganese, 70-80% Mn	gross ton	160.00	—	170.00
Spiegeleisen, 16-20% Mn	gross ton	50.00	—	60.00
Ferro-molybdenum, per lb. of Mo	lb	2.50	—	2.75
Ferro-silicon, 50%	gross ton	85.00	—	95.00
Ferro-silicon, 75%	gross ton	150.00	—	175.00
Ferro-silicon, 10-15%	gross ton	45.00	—	60.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	1.25	—	1.40
Ferro-uranium, 35-50% of U	lb	7.00	—	....
Ferro-vanadium, 30-40% per lb. of contained V	lb	5.50	—	7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.60	—	$0.85
Chrome ore, 48% and over	unit	1.00	—	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00	—	7.50
*Coke, furnace, f.o.b. ovens	net ton	6.00	—	6.50
Petroleum coke, refinery, Atlantic seaboard	net ton	..	—	14.00
Fluor spar, gravel, f.o.b. mines	net ton	..	—	25.00
Manganese ore, 45% Mn and over	unit	.75	—	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00	—	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75	—	.80
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	9.00	—	15.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	7.50	—	10.00
Uranium oxide, 96%	lb.	2.75	—	3.00
Vanadium pentoxide, 99%	lb.	6.00	—	....
Pyrites, foreign, lump	unit	.17	—	
Pyrites, foreign, fine	unit	.17	—	
Pyrites, domestic, fine	unit	.16	—	.17
Ilmenite, 52% TiO_2	lb.	.02	—	
Rutile, 95% TiO_2	lb.	.11	—	
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75	—	3.00
Zircon, washed, iron free	lb	.10	—	
Monazite, per unit of ThO_2	unit	42.00	—	....

*Government prices.

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb	$2.15
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.15
Tees, 3-in. and larger	100 lb.	2.15
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conchead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. fo 19 to 24 gage; for galvanized corrugated sheets, add 15c. all gages

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN — The Lehigh Portland Cement Co., Allentown, Pa., will build 2 large mills near here, one at Legarde and the other at Read's Mill. Estimated cost, $5,000,000.

California

OAKLAND—The Palmolive Co., 42 4th St., Milwaukee, Wis., plans to build a soap factory, here. Estimated cost, $400,000.

PASADENA—The Throop College of Technology will receive bids until March 10 for the construction of a laboratory. Estimated cost, $150,000. B. Goodhue, 2 West 47th St., New York City, archt. and engr. Noted Feb. 4.

Connecticut

DANBURY—The Danbury Roller Bearing Co., c/o Sunderland & Watson, archts., 248 Main St., has awarded the contract for the construction of a 2-story, 55x85-ft. manufacturing plant, to L. F. Sweeney, Montgomery St. Estimated cost, $25,000.

HARTFORD—The City School Bd. plans to build a 3-story high school on Maple Ave. and Benton St. Physical and chemical laboratories will be installed in same. Estimated cost, $1,250,000. Whiton & McMahon, 36 Pearl St., archts.

MERIDEN—The International Silver Co., 48 State St., has awarded the contract for the construction of a 1-story, 42x130-ft. manufacturing plant on Brooks St., to J. H. Grozier Co., 756 Main St., Hartford. Estimated cost, $25,000.

PLAINVILLE—The Standard Steel & Roller Bearing Co. is having preliminary plans prepared for the construction of a 1-story factory at the present factory site. Estimated cost, $75,000.

WINDSOR—The General Electric Co., Lynn, Mass., has awarded the contract for the construction of a 3-story, 60x200-ft. factory on its plant here, to W. M. Bailey Co., 88 Broad St., Boston, Mass. Estimated cost, $80,000.

Georgia

ATLANTA—The Corrugated Paper Products, Inc., has awarded the contract for the construction of a 2-story, 150x185-ft. factory on Stephens St., to the Massell Constr. Co., 305 Healy Bldg. Estimated cost, $60,000.

Idaho

ASHTON—The village will receive bids until March 23 for the construction of a sewage disposal plant, etc. Estimated cost, $120,000. Cotton & Wilson, Post Bldg., Idaho Falls, engrs.

Illinois

CHICAGO—The Koppers Co. is building a plant consisting of 100 byproduct ovens and a 20,000,000 cu.ft. water gas plant for supplying gas to the city mains on the drainage canal near the city limits.

CHICAGO—The Matchless Metal Polish Co., 840 West 49th Pl., will soon award the contract for the construction of a 2-story, 100x125-ft. factory on 49th Pl. and Halsted St. Estimated cost, $75,000. A. G. Lund, 453 West 63rd St., archt.

Indiana

EVANSVILLE — The Liquid Carbonic Co., Heidelback Ave. and Indiana St., is having plans prepared for the construction of a 2-story, 80 x 150 ft. factory. Estimated cost, $50,000. Clifford Shapbell & Co., archts.

Kansas

BLUE MOUND—Meese & Co. plans to move its old mill from St. Louis, Okla., here, and is in the market for rock drills, rolls and tables. George Meese, supt.

Louisiana

MANSFIELD — The Associated Producing & Refining Corp., Shreveport, plans to build a 5,000-bbl. refinery unit, here, ultimate capacity, 10,000 bbl. Malcolm Burns, pres.

RUSTON—The Russell Petroleum Co., of Ruston, plans to build a 1,200-bbl. refinery. Estimated cost, $120,000.

Maryland

CURTIS BAY (Baltimore P. O.)—The Sterno Corp. is having plans prepared for the construction of a plant for the manufacture of heating devices for automobiles and boats, on a 37-acre site along the waterfront, here. Estimated cost, $1,500,000. Carl Hauer, Jr., c/o U. S. Industrial Alcohol Co., resident dir.

Massachusetts

DORCHESTER—The Mason Regulator Co., 1190 Adams St., has awarded the contract for the construction of a 2-story addition to its manufacturing plant on Adams St., to the J. T. Scully Foundation Co., 1st St., East Cambridge. Estimated cost, $30,000.

LYNN—The General Electric Co. has awarded the contract for the construction of a 3-story, 60x100-ft. addition to its plant, to C. W. Wright, 23 Central Ave. Estimated cost, $50,000.

Missouri

DUENWEG—The Clear-Peacher Mining Co. is building a new mill at its lead and zinc mine, here. The company is in the market for 1 compressor, 1 crusher, 2 sets rolls and 4 tables. Fletcher Clear, genl. mgr.

ST. LOUIS—The Mississippi Glass Co., 4070 North 1st St., has awarded the contract for the construction of a 1-story, 83x104-ft. glass factory at 83-91 Angelica St., to the Unit Constr. Co., Title Guarantee Bldg. Estimated cost, $26,000.

Montana

FORSYTH—The city plans to construct a complete sewage disposal plant, etc. A $40,000 bond issue has been voted upon for this project. W. C. Record, engr.

Nebraska

BROKEN BOW — F. M. Skillman, city clk., has awarded the contract for the construction of a sewerage system, including a disposal plant, to Smith & Chambers, Scotts Bluff. Estimated cost, $167,000. Noted Sept. 14.

New Jersey

TRENTON—The National Porcelain Co., Southard St., plans to build a 2-story, 50x72-ft. porcelain plant. Estimated cost, $20,000. R. G. Consolloy, 211 Commonwealth Bldg., archt.

New York

OGDENSBURG — Cooper's Brass Wks., Inc., is in the market for brass furnaces, etc. Address Robert J. Donahue.

ROCHESTER — The Virginia-Carolina Chemical Co. plans to construct a fertilizer factory on Lyell Ave. and the Barge Canal. Estimated cost, $500,000.

North Carolina

BURLINGTON—The Mayor will soon award the contract for furnishing filter apparatus, etc., in connection with the proposed waterworks system. The Ludlow Engrs., Winston-Salem, engrs.

North Dakota

COOPERSTOWN—The City Council will soon award the contract for the construction of a water softening plant in connection with the proposed waterworks improvements. Estimated cost, $79,000. Dakota Eng. & Constr. Co., Valley City, engrs.

COOPERSTOWN—The City Council will receive bids until March 8 for the installation of a septic tank, etc. Estimated cost, $56,000. Dakota Eng. & Constr. Co., Valley City, engrs.

LEEDS—The City Council will soon award the contract for the construction of a septic tank for the sewerage system. Estimated cost, $25,000. T. R. Atkinson, Bismarck, engr.

MAYVILLE—The City Council will soon award the contract for the construction of a filtration and water softening plant. Estimated cost, $25,000. T. R. Atkinson, Bismarck, engr. Noted Feb. 25.

Ohio

CINCINNATI—The Davis Welding Co., 1543 Queen City Ave., plans to build a factory on Borden St. Estimated cost, $150,000.

CLEVELAND—The Cleveland Automobile Co., East 131st St., is having plans prepared for the construction of a 1-story, 80x80-ft. heat-treating plant on London Rd. Estimated cost, $60,000. Ernest McGeorge, 1900 Euclid Ave., archt. and engr.

COLUMBUS—The Climax Rubber Co., Citizens Bank Bldg., has purchased a 7½-acre site on Northwest Blvd. and plans to construct a 3-story, 100x300-ft. rubber factory on same.

Oklahoma

ADA—The city has awarded the contract for the construction of a sewage disposal plant, to Yates & Gallamore, Ada, at $46,936. Noted Oct. 15.

CLAREMORE—The E. B. Rankin Oil & Refining Co. plans to build a 1,500-bbl. refinery, here. Estimated cost, $150,000. Address E. B. Rankin, Sapulpa.

PICHER—The Hunt Mining Co. is building a new 250-ton mill to replace the one recently destroyed by fire, and is in the market for new machinery. C. C. Whittier, supt.

PICHER—Moses & Marcum are moving the old Grayston mill from Tanyard Hollow to this city, and are in the market for gas engines, rolls and 6 tables. J. G. Marcum, supt.

ST. LOUIS—The Aztec Mining Co. plans to build a 250-ton mill at its lead and zinc mine, here, and is in the market for entire new equipment. Harry Larsh, supt.

TULSA—The Robinson Packer Co., 226 East 3rd St., plans to build a 2-story, 90x130-ft. factory at 209-17 North Main St., for the manufacture of oil well supplies. Estimated cost, $100,000. O. K. Eysenbach, pres.

Pennsylvania

LEMOYNE—The Pennsylvania Concrete Tile Roofing & Cement Products Co. will build a 1-story, 40x100-ft. factory for the manufacture of cement products. Estimated cost, $6,000. Work will be done by day labor.

PITTSBURGH—The Philadelphia Co., 435 6th Ave., has awarded the contract for the construction of a large blue gas plant near here, to the Bartlett Hayward Co., Scott and McHenry Sts., Baltimore, Md. The company has been compelled to build this plant owing to the shortage of natural gas.

West Virginia

SISTERSVILLE — The John B. Scohy Glass Co. is building a glass factory.

Ontario

NIAGARA FALLS—W. J. Seymour, City Clk., will receive bids until March 15 for furnishing a 35 gal. capacity chemical tank, etc. D. T. Black, Erie Ave., engr.

PETERBORO — The Canadian Aladdin Co., Canadian Pacific Ry. Bldg., has awarded the contract for the construction of a 3-story, 60x80-ft. factory for the manufacture of electric bulbs, etc., to the Dickie Constr. Co., Pyrie Bldg., Toronto. Estimated cost, $125,000.

TORONTO — The Keystone Products, Ltd., 133 Eastern Ave., is in the market for 1 second-hand electric furnace, etc.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will hold a meeting on March 26, the subject of which is "Peace Uses for War Products."

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE CANADIAN MINING INSTITUTE will hold its annual meeting at the King Edward Hotel, Toronto, March 8 to 10.

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theatre: "Helium," Monday, March 29, at 4 p.m., Dr. R. B. Moore, chief chemist, U. S. Bureau of Mines (*Lantern*); "Romance of Leather Making," Tuesday, April 13, at 4 P.M., E. A. Brand (*Lantern*); "Water Supply and Drainage in War Cantonments," Wednesday, April 21, at 4 P.M., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers Process), Thursday, April 29, at 4 p.m., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 P.M., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 P.M., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern*).

THE FARADAY SOCIETY (London) will hold a meeting on March 23, at which there will be a general discussion on "Basic Slag From the Metallurgical and Agricultural Standpoints."

THE INSTITUTE OF METALS will hold its annual general meeting March 11 and 12 at the Institute of Mechanical Engineers, Storey's Gate, Westminster, S. W. 1, London, England.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning October 4.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Industrial Notes

THE BLAW-KNOX CO., Pittsburgh, Pa., has purchased the C. D. Pruden Co. of Baltimore, Md., manufacturer of standardized steel buildings for industrial plants, warehouses, cottages and garages. The Blaw-Knox Co. also announces that J. Grier Campbell, purchasing agent of the company, has resigned to become assistant treasurer of the C. D. Pruden Co. and that W. S. Boyd, formerly assistant purchasing agent of the Crucible Steel Co. and purchasing agent of the Page Steel & Wire Co., has been appointed purchasing agent of the Blaw-Knox Co. to succeed Mr. Campbell.

THE PHILADELPHIA TEXTILE MACHINERY Co., Philadelphia, Pa., manufacturer of drying machinery, has opened an office in the East River Bank Bldg., 291 Broadway, New York, of which H. S. Landell will be in charge.

THE EASTON CAR & CONSTRUCTION Co., New York, has opened a branch office in Room 400, Penobscot Bldg., Detroit, Mich., in charge of H. H. Siff, the district sales engineer. This company announces that this branch office will carry a stock of spare parts as soon as the demand for such service makes it advisable.

THE EASTERN PRODUCTS Co., of Putnam, Conn., has been incorporated to deal in chemicals, dyes, etc. The company will start with a capital of $25,000, and the organizers are as follows: Samuel Smith, 64 Ring St., Putnam; George F. Bidwell and G. A. Bidwell, both of Putnam, Conn. Address all matters to Samuel Smith, president.

THE NATIONAL CHEMICAL PRODUCTS Co., of 59 Elm street, Stamford, Conn., has been organized to make and deal in chemicals, etc. The officers of the new company are as follows: Philip Sewdosh, president; B. Troupin, vice-president; Eli S. Troupin, secretary and treasurer. Mr. Sewdosh is an experienced chemical man, and both B. Troupin and Eli S. Troupin are in the drug business in Stamford. The new company is now in operation.

THE MAHER ENGINEERING Co. of 30 North Michigan Ave., Chicago, announces the opening of a branch office under the direction of Lincoln E. Maher at 708 Scofield Bldg., Cleveland, Ohio. This office will distribute Erie Engine Works engines, Dayton-Dowd Co. centrifugal pumps and Galland-Henning hydraulic presses.

THE INTERNATIONAL ACETYLENE ASSOCIATION is making a census of schools where the art of oxy-acetylene welding is taught. The purpose of this census is to assist the association in answering inquiries from persons desiring to secure competent artisans in this kind of work. A blank form will be sent to any institution desiring to be registered with the association.

FREYN, BRASSERT & Co., Peoples Gas Bldg., Chicago, has made arrangements with the Gellert Engineering Co. of Philadelphia, Pa., for the mutual handling of Cottrell electrical blast-furnace gas cleaners for the entire world. Freyn, Bassert & Co. will have exclusive charge of sales and will co-operate with the Gellert Engineering Co. which is the exclusive builder of the Cottrell cleaner in the United States in the installation and practical adaptation of this apparatus to the particular requirements of blast-furnace practice.

Creditors of the METALS PRODUCTION EQUIPMENT Co. (bankrupt), Springfield, Mass., are notified that a second dividend of 10 per cent has been declared on all claims which have been proved and allowed but not entitled to priority. The trustee has been ordered to pay in full all claims which have been approved and allowed and are entitled to priority. The dividend is payable by Trustee Harry C. Dodge, Boston, Mass.

SIR RALPH FORSTER, Bart., has given £34,500 to the fund for building and equipping the chemical laboratory of University College, London. The department of organic chemistry will be called the Forster Laboratory.

Manufacturers' Catalogs

THE HAUCK MANUFACTURING Co., Brooklyn, N. Y., has issued a new bulletin, No. 119, illustrating and describing in detail its different types of oil burners. The catalog contains results of tests which are of particular value.

THE WELLMAN-SEAVER-MORGAN Co., Cleveland, Ohio, has just issued Bull. No. 49, giving views of a number of types of car dumpers together with blue prints of these machines. Copies will be sent upon request to any one interested.

PYROLECTRIC INSTRUMENT Co., Trenton, N. J., is issuing its January, 1920, bulletin, No. 10, the subject of which is "Secondary Standards of Inductance," by E. F. Northrup. This bulletin formerly came out once a month but now comes out bi-monthly, starting with this issue.

ELECTRO BLEACHING GAS Co., Niagara Falls, N. Y., announces a new publication entitled "Liquid Chlorine," which contains illustrations and descriptive matter.

N. B. PAYNE & Co., New York City, has just issued a new bulletin entitled "Lane Electric Cranes." This company is the sole agent for Lane electric cranes, manufactured in Montpelier, Vt., by the Lane Mfg. Co. The bulletin fully illustrates and describes several styles of cranes in which steel girders or heavy timbers of long leaf yellow pine are used. It contains a complete set of specifications and a list of users. A questionnaire is inserted in the bulletin for the use of the prospective purchaser on which can be written all information needed by the manufacturers. A free copy will be mailed upon request.

THE AMERICAN PULVERIZER Co., East St. Louis, Ill., announces Cat. No. 53 on the pulverizer that solves your problem. Illustrations and descriptive matter are given, including the standard pulverizers, coal crushers, shredder and disintegrator, and chemical machines.

THE ELECTRIC FURNACE Co., Alliance, Ohio, is distributing Booklet 8-B, entitled "Some Installations of Baily Electric Furnaces," melting non-ferrous metals. This booklet is profusely illustrated, with some descriptive matter, together with a list of the sizes built.

WESTINGHOUSE, CHURCH, KERR & Co., INC., New York, has issued a leaflet entitled "W. C. K. City." A large photograph is given showing many buildings erected by this company, which include manufacturing plants, shops, foundries, power plants, railroad terminals, hotels, etc., together with descriptive matter.

THE DELAVAL SEPARATOR Co., New York, has published Bull. No. 200, on the De-Laval method of centrifugal clarification of varnishes, japans and pigment goods, illustrating and describing multiple clarifiers, centrifugal filters, belt-driven machines, also the mechanical construction of the centrifugal machines, how the multiple clarifier bowl works and how the centrifugal filter bowl works.

THE KOPPERS Co., Pittsburgh, Pa., has issued a booklet on "Coal and Byproducts."

THE NORTHERN EQUIPMENT Co., Erie, Pa., calls attention to a 24-page booklet, entitled "Saving Fuel Automatically and Scientifically in the Boiler Room," based upon matter that was prepared for the United States Fuel Administration during the war. In the preface of the booklet the manufacturers say: "When the war ended we thought we had done our duty, and that the fuel situation would ease up a bit. However, we find the fuel problem now becoming serious. Prices will not come down because wages will evidently stay up or will go higher." The booklet compares hand and mechanical feeding with mechanical regulation, as performed by the Copes Regulator. It shows what is to be desired in the way of scientific boiler feed regulation. Many charts and diagrams are shown to emphasize the value of scientific control, together with a list of the users of Copes Regulators.

THE MEAD-MORRISON MFG. Co., East Boston, Mass., has issued a very attractive catalog, No. 21, on hoisting machinery. The catalog contains 166 pages illustrating and describing the different types of hoisting machinery for coal, ash and ore handling machinery, steam hoists, electric hoists, belt and gasoline hoists and grab buckets.

PORTABLE MACHINERY Co., INC., Passaic, N. J.: A bulletin has just been issued on portable belt conveyors for handling material horizontally or at a slight incline which are described and illustrated. It contains prices of these machines which are made with 16-in. wide belt and in standard stock sizes as follows: 12 ft. 6 in.; 16 ft.; 19 ft. 6 in.; 23 ft.; 26 ft. 6 in.; 30 ft.; 33 ft. 6 in., and 37 ft. These machines in addition to being used for handling coal, sand, crushed stone, fertilizer, etc., can be used for conveying many manufactured products, bagged material such as cement, etc.

THE INDUSTRIAL GLOVES CORP., Chicago, Ill., is issuing a booklet on industrial gloves and mittens. Illustrations and descriptive matter are given on gloves, mittens, arm protectors, hand pads, leggings and aprons, together with the prices.

THE GRISCOM-RUSSELL Co., New York, desires to announce Bull. No. 231, on the G-R instantaneous heater.

THE INDUSTRIAL PRODUCTS Co., Mutual Life Bldg., Philadelphia, has published a folder illustrating and describing industrial acid hoods and suits. These are products of acid-proof rubberized cloth designed to protect those who have to deal with acid lines, storage tanks and processes in which acids are used.

W. S. ROCKWELL Co., New York City, has issued Bull. 208, "The Function of Oil Burners in the Operation of Furnaces." This bulletin is being distributed with the idea of correcting the erroneous impression held by some regarding the real function of oil burners in the operation of furnaces.

Food Drafts for Relief of Europe

SUPPORTING an appeal from HOOVER is becoming almost a habit with engineers. Beginning with Belgian Kiddies, Ltd., and running through the whole list of plans for the relief of the war-stricken peoples of Europe, members of the engineering profession have gladly lent their support to projects which they knew were worthy. The latest plan devised for the relief of Europe's hunger is the sale of "food drafts" which can be bought at banks in the United States, mailed abroad and exchanged for the equivalent value in food at any one of five central warehouses in Europe. Mr. HOOVER appeals to engineers who are employers of foreign-born labor to bring to the notice of these workmen the easy possibility of assisting their friends and relatives in Europe who may be without sufficient food. As outlined in a letter from Mr. HOOVER, printed elsewhere in this issue, the plan is very simple. Bankers throughout the United States will sell food drafts authorizing the American Relief Administration warehouses at Hamburg, Warsaw, Vienna, Prague or Budapest to deliver to a named individual food to the value of the draft, $10 or $50. Hungry Europe needs food and not money; and under the arrangement between the American Bankers Association and the American Relief Administration, it is possible to supply food in addition to that which is available under the rationing system. The plan is highly practicable and we bespeak for it wide publicity and adoption.

Co-ordinating Scientific And Industrial Effort

IF THE war demonstrated one thing more than another to industry in this country, it was the inefficiency of rule-of-thumb methods and the necessity of scientific control. In many cases industrial executives made their first acquaintance with technically-trained men, and while the gap between the educational institutions and the industrial interests of the country cannot be said to have been completely bridged in all instances, it was materially narrowed. Following closely upon our war experience came the Massachusetts Institute of Technology with a plan for co-ordinating its interests with those of our industries in such a way as to promote the welfare of both education and business. Originally evolved as part of Tech's plan to secure endowment funds, the idea is full of promise for the recognition of science and those who apply it. For the next five years the Institute will introduce science to industry through co-operation between its own faculty, students and graduates and those concerns which have contributed to the endowment fund. This will mean five years of accustoming industry to the habit of seeking advice at the hands of scientists and technologists, at the end of which time a foundation will have been laid for the recognition of chemical and industrial engineers in a greater degree than would otherwise be possible. It should mean five years of the most rapid industrial progress ever made in this country. Details of the Technology Plan, outlined in this issue by Professor WALKER, reveal an idea which can be adapted to other institutions of learning. Indeed we are informed that Cornell already has adopted the plan, and we are assured by the Institute that other colleges and universities are welcome to do so. It was highly successful with its originators, over 190 contracts being made, having a money value in excess of $1,200,000.

Sewage Disposal And Physical Chemistry

SOME of us who have arrived at years which we hold to be those of discretion, but which are not generally considered to indicate the peak of man's productivity, are likely to grow a little testy about physical chemistry. This is especially the case if we have been lazy in our reading, or if we have let our mathematics and physics drift into those cloudy regions of memory where we keep our Latin grammar and our Greek verbs. We are apt to forget the available fields of research which should precede the methods of trial and error. We wonder if this has not been the case in regard to sewage disposal.

We have considered oxidation in many aspects, chlorination of effluents, the SO_2 reaction and a few other indefinite chemical phenomena, and thereupon we have addressed ourselves to the engineering problems. So we wonder if we have not begun with engineering a little too soon. If there is anything that the conscientious engineer needs to know, no matter of what particular kind he may be, it is the nature of his materials. Now, sewage and its disposal is largely a problem in colloid chemistry, and it may be that the subject has not been adequately studied from the colloid point of view. The chemical behavior of solid substances is largely dependent upon the surface of their particles, and this in turn is determined by the size of them. In such a miscellaneous mess as sewage we have presented a vast field for colloidal study, and the treatment is bound to be chemical if we would change its nature so as to rid it of offensiveness.

It may be that talent and scholarship of the first order in physical chemistry have been addressed to this subject, but if this be true the fact has escaped us. What we should like to see would be a comprehensive study undertaken of the physical chemistry of sewage in a laboratory where modern physicochemical methods of research prevail. It would give the engineers a better show—a better opportunity to design apparatus to meet existing conditions. It may be possible to

coagulate sludge and to separate it from the effluent in a much more effective manner than we now know. With an improved method of separation established it might open the road to a real solution of this perplexing problem. The record of chemistry in regard to sewage is not complete. The case is not closed. Our rivers are still canals of filth, while they carry off to the sea a wealth of nitrogenous material of which we are still in such need that we are at our wits' end to produce it.

An Engineer At the Shrine

These are predestined: if a man love the labour of any trade, apart from any question of success or fame, the gods have called him.

STIMULATED by the vision of a glass maker in his old apron and battered hat, H. L. DIXON recalled the days of twoscore years ago to the enlivenment of the ceramists at their meeting in Philadelphia. One who has thus been associated with an industry from its infancy, who has seen it become a giant in production, is to be envied indeed. All the best in life is not found in things intellectual. There is a call in the heart of every engineer to the handicraft of his business.

Ridiculous Substitute For the Metric System

OPPOSITION to the proposal to make the metric system compulsory in the United States has produced many foolish arguments, but up to date we have observed nothing quite so inane as the proposal contained in Senate Bill 3,943, the purpose of which is "to establish the standard and decimal divisions of weights and measures and coins of the United States." The bill was introduced "by request" by Senator KING of Utah, who is probably the willing or the unwilling victim of a zealous fanatic.

The bill proposes that after January 1, 1921, the standard for the measure of length and distance shall be the foot, as heretofore. One-tenth of a foot shall be a "decimal inch," one one-hundredth shall be a "line" and one one-thousandth of a foot shall be a "point." One-twelfth of a foot shall also be denominated a "common inch." The multiples of the foot shall be the "double foot, the yard, the quad, the fathom, the decad, the rod, the hundred, the furlong and the mile," whereby, under the grand old Arabic rule of decimal computation, 16½ ft. make one rod and 320 rods make a mile. (Why discriminate against the ancient "cubit," which was standard when NOAH built the Ark?) In measuring plane surfaces a square foot shall be called a "square," and the acre remains, as before, composed of 160 square rods. For volume we are to take a great leap forward by calling a cubic foot a "cube," and the cube of the "decimal inch" shall be called a "decimal cube."

For the measurement of weight we shall have a kind of an ounce which shall be "the weight of the decimal cube of water at maximum density." The decimal divisions of the ounce shall be the dram and the grain, "of which one hundred grains equal one dram and ten drams equal one ounce." Here the zealot's sub-conscious mind evidently referred to fluid measure in the dram, but as our memory serves us one-tenth of an ounce would make a very small pony. A more popular conception of a dram would be a jigger.

Ten ounces are to constitute one decimal pound, and one hundred decimal pounds one "weight unit," while eight "weight units" equal one "quarter" and ten quarters equal one ton. We shall also have the "common pound" of sixteen ounces. The liquid ounce is to be one decimal cube, and ten liquid ounces will be one decimal pint, while a thousand liquid ounces will be one "liquid cube." For dry measure we are to have "the quart, the pot, the gallon, the peck and the half cube." The mechanical power unit shall be that required to raise one "weight unit" one foot in one second. "The thermal unit shall be the quantity of heat required to raise one ounce of water one degree of the scale of the Fahrenheit thermometer," and we don't know what kind of an ounce it is. For coinage we are to have the dollar, the two-franc piece, the franc and the dime; the nickel, the penny and the cent; and in gold the pound, the eagle and the double eagle.

When we first heard of this bill we presumed it to be a joke, but on receiving a copy from Senator KING we found it to be a fact. We protest against the folly and waste involved in the legislative process of introducing such a bill. The cost of printing and the time of the Senators in session and of the Committee on Weights and Measures to consider and throw out such a fool bill mount into the thousands of dollars, all paid for in taxes by the people of the United States. Besides this we have to consider the far more important interruption of business of world-wide importance, all of which is wasted to meet a fanatic's pleasure. We wonder if there is any possible way of bringing to the consciousness of Congressmen the fact that neither their pleasure nor their political advantage in such matters is worth the price? Compared with this measure the proposal to make the metric system obligatory is the height of sanity; but this sort of a thing, with its different kinds of ounces and inches, its "drams," its "weight units," its "lines," "points," "pots," and so forth, would make confusion worse confounded, as everybody knows. We suggest that if the gifted gentleman who proposed the plan wants to be original. he substitute his ear as the standard of length, thus insuring good measure.

Speaking of Standard Weights and Measures

BROWSING around in ancient literature is usually entertaining, sometimes instructive and occasionally profitable. In an old work on metallurgy and assaying, published in 1799, under the title "Nueva Teórica y Práctica del Beneficio de los Metales de Oro y Plata por Fundición y Amalgamación," JOSEPH GARCES Y EQUIA describes a progenitor of our modern system of assay-ton weights.

Our author and inventor (if, indeed, the idea be original with him) proceeds somewhat as follows:

> For fine work, requiring a scorification assay, take one adarme [a Spanish weight equivalent to about one-sixteenth of an ounce troy] and call that a quintal ["assay quintal" being inferred] and divide the adarme into one hundred equal parts, or units, which we will call an [assay] pound. This unit divide again into sixteen parts, which we will call an [assay] ounce. Then by taking an adarme of the sample and using our system of weights we get a figure which corresponds to the pounds and [or] ounces of metal per quintal of ore.

There is also developed a similar system for the calculation of silver expressed in marcos per carga.

Thus we have further proof, if there be need of such, that there is nothing new under the sun.

Political and Commercial Nitrogen

UNBIASED views are particularly valuable at this time in attempting to get a clear-cut view of the situation relative to nitrogen and its compounds. As CHESTER G. GILBERT states elsewhere in this issue, "The discordant grinding of many axes makes a noise from which it is impossible to gather an adequate comprehension" of the facts. The comment is pertinent and is also indicative of the freedom from prejudice with which the author approaches his subject. We commend a careful study of Mr. GILBERT'S views to all who would comprehend the political and commercial activities relative to nitrogen.

The article will also be enlightening to members of Congress and other laymen who have in the past failed to distinguish the terms nitrogen, air nitrates, nitrification, fixation, etc., one from the other. Mr. GILBERT'S discourse is quite within the comprehension of the uninformed.

Nitrogen in tangible and usable form is important to our welfare at all times. The demand for fertilizers is increasing at a rate exceeding the supply, in spite of increased production caused by the war. Consequently, the future policy of the Government and of private industry cannot be decided without serious study, nor can final action be passed on personal or political prejudices. The price of nitrogen in fertilizer has been determined by the cost of the Chilean product, and there is little reason to infer that this condition will be altered for some time to come, even if the Government should operate its own plants.

Steel Corporation Does Not Violate the Sherman Law

IN NEARLY all circles there is an overwhelming feeling of satisfaction that the United States Supreme Court has declared that the United States Steel Corporation is not a violation of the Sherman law. The competitors of the Steel Corporation are well satisfied, its customers are well satisfied and its employees have great grounds for satisfaction. A few doctrinaires and lawyers may be dissatisfied.

It is of interest to note that the law under which the Government instituted its suit October 26, 1911, ten and a half years after the Steel Corporation came into existence, the act approved July 2, 1890, is officially entitled "An act to protect trade and commerce against unlawful restraints and monopolies." The text of the law does not so state, but the circumstances attending its passage have been regarded as indicating that the object was to clarify the existing common law into a definitely worded statute, rather than to prohibit things previously regarded as clearly lawful. To the ordinary observer the evidence has been plain that the corporation's conduct, at least in recent years, has not been such that trade and commerce needed to be protected against it. There are few, undoubtedly, who would deny that the existence of the corporation actually encouraged the growth of independent production.

Nevertheless, the record of the case is that the decision in favor of the Steel Corporation was by a four to three division in the Supreme Court, and that two Justices whom circumstances prevented from participating in the case are commonly assumed to feel unfavorably toward the corporation. It is also to be noted that the majority opinion cites that it would be injurious to the public interest for the corporation to be dissolved and that the Government omitted to outline a definite method by which dissolution could be effected, giving the dissenting Justices opportunity to assert, in essence, that the law should not be ignored because its execution presents difficulties. It can hardly be said, therefore, that the corporation secures anything at all beyond a mere termination of the suit in its favor, from the legal viewpoint.

Neither the majority nor the dissenting opinion can be found to add anything important to the interpretation of the Sherman law, yet the divergence of the opinions rendered is a definite indication that further clarification of the law is very desirable.

There were many defendants in this suit, all of whom won through the decision, but the really great victory was won by ex-Judge ELBERT H. GARY, chairman of the Steel Corporation since its formation nineteen years ago. Beyond peradventure of doubt it was Judge GARY'S policies that saved the United States Steel Corporation from defeat in the Supreme Court. Judge GARY did vastly more than keep the Steel Corporation from doing things that would have invited an adverse decision in the court. He helped the corporation, directly and in great measure, to succeed in a business way.

The case was really decided upon the conduct of the Steel Corporation. If the decision had been based upon the expectations and intentions of those who brought about the prior consolidations and the formation of the Steel Corporation itself, it requires little reflection to reach a conclusion that the decision would have been different, but the decision plainly writes such expectations out of the case.

This suit of more than eight years' standing being decided, the natural question is, What next? At various times a consolidation of a number of the larger independents has been discussed. It seems fairly clear that no large consolidation could be safe from legal attack. With a four to three decision in favor of the Steel Corporation, which is approximately a 44 per cent interest in point of finished steel-producing capacity, the spectacle of the steel industry's capacity being very largely in the control of two companies would hardly be viewed approvingly.

There is absolutely no reason to assume that the Steel Corporation's price and sales policies will be altered at all by the settlement of the suit. The Steel Corporation's steadfast adherence to March 21 or Industrial Board prices for steel, even beyond the calendar year for which they were formulated, rests upon important business considerations, rather than legal considerations, and undoubtedly has the strong approval of financial interests that are so well represented in the corporation's counsels.

As to investments in plant facilities, on the other hand, there is good reason now for the Steel Corporation to modify its policy. When there was hanging over it the threat of a dissolution, it was imperative that the corporation maintain as large liquid reserves as possible, against the arrangements that would be forced by a decree of dissolution. The occasion for the maintenance of these large liquid reserves has now passed, and the corporation may well address itself, when business conditions warrant, to the investment of a large part of these reserves in property account. In several of its important finished products the corporation now produces somewhat less than 40 per cent of the total produced in this country.

Food Drafts for European Relief

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am sure that my fellow engineers will welcome an opportunity to assist in practical support of the relief measure for the civil population of the larger cities in Eastern and Central Europe. We have inaugurated a simple method by which it is possible

(1) For an individual in America to supply a relative or friend in Europe with a food package on payment in dollars at any one of several thousand banks in America.

(2) For anyone desirous of helping to give to the unfortunate without naming a particular relative or friend.

This is made possible by a "food draft" which can be bought at banks, mailed abroad, and is good for the equivalent in food when presented at any one of our five central warehouses in Europe. About four millions of our people are foreign-born or have close foreign affiliations. A large proportion of these people are operatives in our mines and large technical industries.

This is not a "charity" in the ordinary sense of the term, because we give much more than the same number of dollars could possibly buy in Europe if remitted in money at the present rate of exchange. Further, if the transaction is not completed in ninety days, the purchaser of the draft is entitled to a refund, less a small charge for handling. Profits which may be derived from these operations will be credited to the European Children's Fund for child-feeding in the country where the draft is presented.

I earnestly hope you can devote some space to an appeal to the engineers to make these facts known concerning this food draft system and interest the foreign-born in their employ in its possibilities and value. We want their indorsement and their support.

115 Broadway,
New York City. HERBERT HOOVER.

The Phonograph as an Adjunct to a Research Laboratory

To the Editor of Chemical & Metallurgical Engineering

SIR:—I desire to call attention to the fact that as an aid to scientific research, dictation machines such as the Ediphone or the Dictaphone bid fair to play a prominent part. This is particularly true in so far as the dictation of descriptive data is concerned.

For instance, it is quite feasible for the metallographist to enlist the service of such a help when he has occasion to observe the structure of a specimen under the microscope. His power of description is enhanced, while the field of vision is focused upon the retina. Furthermore, he is in a position to portray vividly the image in its minutest detail.

The prevalent method of recording microscopic data in most research laboratories is to explore the specimen and then write a description of such details as remain fresh in the mind. Much valuable information is lost in this manner; the investigator is later often desirous of writing a more detailed report, but he finds it difficult to depict exactly what he saw.

It is true that microphotographs are a valuable adjunct to scientific research, but their value generally lies in the phrases that describe them. Moreover, microstructures can be more sharply resolved under the eye piece than on photographic paper, except when the exposure, development and printing are done in the most expert manner.

Briefly stated, the investigator should find it to his advantage to dictate his observations the moment he sees them, and not rely upon memory.

The use of the phonograph may obviously be extended to kindred sciences, such as chemistry, biology, bacteriology and microscopic analysis. V. E. HILLMAN.

Worcester, Mass.

A Rapid Method for the Analysis of Monel Metal

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have been very much interested in an article appearing in your magazine of Jan. 7, 1920, written by Philip Covitz, entitled, "A Rapid Method for the Analysis of Monel Metal."

To make the method still more rapid, I would suggest the following:

Starting from the filtrate taken from the silicon determination; the filtrate should not consist of more than 125 c.c. Make this solution ammoniacal, which precipitates the iron and aluminum as hydroxides. If much copper is present, a double precipitation is necessary. Dissolve the precipitate in hydrochloric acid, dilute and add about 25 c.c. of a 10 per cent solution of sodium phosphate. Then make ammoniacal, then neutralize with hydrochloric acid, adding not more than 3 c.c. in excess. To this solution add 25 c.c. of a 40 per cent boiling solution of sodium thiosulphate. Boil for at least 10 min. and filter off the precipitate of aluminum phosphate. Wash the precipitate at least five times with boiling hot water and ignite in a porcelain crucible and weigh. Make the filtrate ammoniacal, boil and filter. Dissolve the precipitate of iron, which is in the form of iron hydroxide, in hydrochloric acid, reduce with stannous chloride and continue the determination for iron as given by Mr. Covitz.

I think this method is more simple and will require less amount of time for the determination than the one as outlined by Mr. Covitz because a separate weighing is not necessary for the iron and aluminum determination, as these two elements can be taken from the filtrate of the silicon determination, and because less time is consumed in the method that I have outlined above. H. A. HORNER.

American Metallurgical Corp.,
Philadelphia, Pa.

Potash From Lakes in Nebraska

To the Editor of Chemical & Metallurgical Engineering

SIR:—Through an unintentional oversight a section of the article on Potassium Salts in vol. 27 of *Mineral Industry* entitled "Potash From Lakes in Nebraska" on pages 584 and following does not give credit in the text to the source from which this material was copied, namely, an article by the same name, written by E. E. Thum and published in MET. & CHEM. ENG., Dec. 15, 1917. J. W. BECKMAN.
G. A. ROUSH.

Industrial Safety Codes

On Dec. 8 there was held at the Bureau of Standards in Washington a notable conference on industrial safety codes, at which there were representatives of practically all organizations of a national scope interested in any of these wide phases of industrial safety. The conference grew out of an earlier one held on Jan. 15, 1919.

There was a thorough discussion of the whole situation, the consensus of opinion being that there should be a large number of industrial safety codes—perhaps fifty or even one hundred—developed during the next few years.

The conference unanimously voted that the preparation of all such safety codes should be under the auspices and rules of procedure of the American Engineering Standards Committee.* In accordance with the recommendation of the conference, the American Engineering Standards Committee requested the International Association of Industrial Accidents Board and Commissions, the Bureau of Standards, and the National Safety Council to organize a Joint Committee on Safety Codes, this committee to include representatives of these bodies, and such others as they may consider advisable.

In compliance with this request the three bodies have organized such committee, the personnel of which is: D. S. Beyer, Boston, Mass.; Edward F. Boyle, Albany, N. Y.; C. B. Connelley, Harrisburg, Pa.; L. A. de Blois, Wilmington, Del.; W. C. L. Eglin, Philadelphia; George P. Hambrecht, Madison, Wis., represented by R. McA. Keown, Madison, Wis.; M. G. Lloyd, Washington, D. C.; Royal Meeker, Washington, D. C.; Dana Pierce, New York, N. Y.; C. C. Rausch, New York, N. Y.; Calvin W. Rice, New York, N. Y.; John Roach, Trenton, N. J.; E. B. Rosa, Washington, D. C.; A. W. Whitney, New York, N. Y., and S. J. Williams, Chicago, Ill.

It is planned to add two more members to the committee, one each from the Ohio and the California commissions.

The committee held its first meeting in Washington on Jan. 9, at which time tentative recommendations were formulated for about thirty safety codes. This committee, which represents in its own personnel a large range of interests, is actively at work. It is consulting a large number of other interests involved. Rapid progress is being made and it is expected that the committee will soon render an important preliminary report.

Regulation Affecting Transportation of Denatured Alcohol in Texas

Under the Dean law in Texas, no carrier can deliver denatured alcohol to the consignee without the permit required by this law. The United States Railroad Administration failed to take out such a permit for 1920. The attention of the Texas Chamber of Commerce was called to this situation by the First Texas Chemical Co., of Dallas, its plant having been forced to shut down for lack of denatured alcohol.

Upon telegraphic representations made by the Chamber of Commerce that failure to take out this permit promptly had prevented carriers from delivering denatured alcohol, thereby handicapping the chemical industry in Texas, the regional director ordered that a permit under the Dean law be taken out for Texas railroads then under Government control.

*See CHEM & MET. ENG., Feb. 18, 1920, p. 294.

Civil Service Examinations

The following examinations are announced by the Civil Service Commission:

Petroleum engineer, $3,000 to $4,500 a year; assistant petroleum engineer, $2,100 to $3,000 a year. Vacancies in Bureau of Mines for duty in Washington, D. C., or in the field will be filled from these examinations. Apply on Form 2,118 before March 16.

Geologic aid and assistant geologist for duty with United States Geological Survey at salaries ranging from $100 a month when actually employed to $1,800 a year. Apply at once for Form 1,312. Examination will be held March 17 and 18.

Automatic scale expert for duty in the Customs Service, New Orleans, La., at $1,600 a year. Applicant must be familiar with construction, operation and care of automatic and electric scales. Form 1,312 is to be used in applying for examination, which will be held March 17.

Foreman, heat treatment for armor plate, $10 to $14.40 a day; foreman, heat treatment of large guns, $8 to $12.56 a day. Vacancies at U. S. Naval Ordnance Plant, South Charleston, W. Va. Apply on Form 1,371 before March 23.

Valuation aid, $1,200 to $2,500 a year; assistant valuation engineer, $2,500 to $3,600 a year; valuation engineer, $3,600 to $4,800 a year. Vacancies in technical staff of Income-Tax Unit of Bureau of Internal Revenue, Treasury Department. The duties of these positions will involve estimation of: (1) The quantity of mineral or oil and gas or timber; (2) theoretical and market values of mineral or oil and gas in place or standing timber, and their products; (3) value of equipment used in developing these natural resources; (4) cost of development, exploitation and utilization of these natural resources. Applications will be received on Form 1,312 until further notice.

Meeting of California Section, A. C. S.

The monthly meeting of the California Section of the American Chemical Society was held in the rooms of the Engineers' Club of San Francisco Thursday evening, Feb. 26. Two papers were presented. The first, by Dr. W. C. Bray of the University of California, on "The Practical Application of Catalysis," dealt with the successful development of catalysis for use in gas masks to bring about the oxidization of small amounts of carbon monoxide. The second paper was by Dr. E. D. Eastman, of the University of California, on the subject of "The Reduction of Iron Oxides by Fuel Gases." Dr. Eastman discussed the theoretical aspects of the subject, which was studied with the object of determining the practicability of the production of iron from the calcines resulting from roasting sulphide copper ores containing pyrites, the iron produced by this process to be used for the precipitation of copper from sulphate solutions.

Land Leasing Bill

Friends of the oil land leasing bill were kept on the anxious seat until the eleventh hour by the President, who signed the bill on the afternoon of the day on which the bill would become a law automatically. It had been rumored that the President intended to veto the measure. In addition to oil, the act provides for the leasing of coal, phosphate, gas, and oil shale.

BANQUET OF AMERICAN CERAMIC SOCIETY, PHILADELPHIA

The Philadelphia Meeting of the American Ceramic Society

Report of the Twenty-second Annual Meeting—Addresses of the General Session—Selection of the Papers Read Before the Enamels, Glass, Refractories, Terra Cotta and Porcelain Divisions

THE twenty-second annual meeting of the American Ceramic Society opened at the Bellevue-Stratford Hotel in Philadelphia Feb. 23, 1920, with an address by President R. T. Stull, who outlined the need of technical research in the clay industries. There is now manufactured in the United States about $500,000,000 in ceramic products per annum, one-half of which are clay, the remainder enamels, etc. Every state is engaged in the industry. Brick is the largest in tonnage and value.

Seventy per cent of the cost of production is labor and fuel. There is great room for reduction of these costs through the adaptation of mechanical devices and automatic machinery. The price of brick has trebled in the last ten years.

The tunnel kiln will play a large part in fuel economies. The time will come when brick will be produced automatically throughout the process; but no company has the capital to undertake this development at present. Secretiveness and patent conflicts choke the progress. Either a brave corporation must enter the development or a central corporation must be organized with large research laboratory and mechanical plant.

Business Meeting

Reports of the committees showed the business affairs of the society to be in good condition. The total membership is 1,228 with an average increase of twenty-five new members per month. The committee on ceramic research, co-operating with the National Research Council, has proposed establishment of fellowships as a means of solving the fundamental problems. It is necessary to know not only the how but the why. Every works problem is a fundamental one.

These fellowships should be established by the manufacturing companies and there are two classes, as follows:

Class A: The stipend for this class of fellowships shall be $800 for the first year and $1,000 for the second and each subsequent year. A holder of this class of fellowships shall carry out his research work at a university and shall have the privilege of becoming a candidate for an advanced degree at that university, and of taking such advanced courses as may be necessary thereto.

Class B: The stipend for this class of fellowships shall be $1,600 for the first year, $1,800 for the second year and $2,000 or more for subsequent years. The holder of one of this class of fellowships shall be a trained research worker and shall devote all of his time to the research work.

The special committee on definition of the word "ceramics" delivered a long report giving the complete etymology of the term and concluding with the statement that there is no barbarism when the word is applied to the present field of the American Ceramic

Society. Ceramic industries are those which manufacture products by the application of heat to earthy materials, and ceramic engineering is that branch of engineering which deals with the ceramic industries.

Election of Officers

The election of the following officers was announced for 1920: R. H. Minton, president; E. T. Montgomery, vice-president; R. K. Hursch, treasurer; Charles F. Binns, secretary; F. H. Riddle, member of board of trustees; Homer F. Staley, editor of the *Journal*.

Papers Presented

A total of 139 papers read and a symposium on tunnel kilns compared favorably with the fifty-eight offerings of last year. Monday was devoted to the

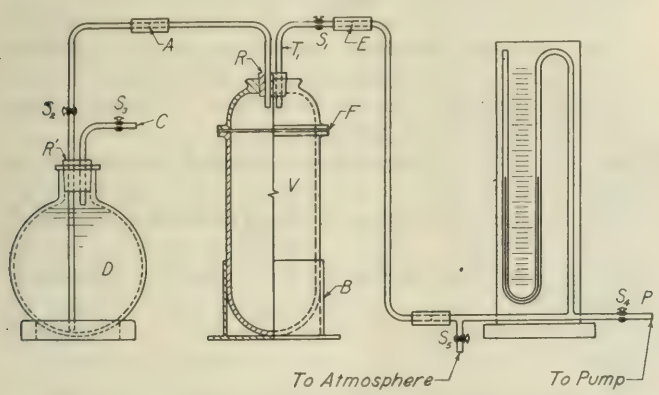

FIG. 1. APPARATUS FOR TESTING POROSITY

presentation of general papers, while the following days were occupied in divisional meetings.

Classification of Clays

A. S. Watts proposed a classification of clays on a ceramic basis. At present there is much confusion as to the definition of kaolin. This is true of ball clay, and the specification regarding fire clay is even more vague. Fire clay is now understood to refer to "coal-measure clay." It should be based on refractoriness, say above cone 27. General classification should be made according to ceramic properties as evidenced by color, shrinkage, bonding strength, vitrification and fusion.

Testing of Clay for Light-Weight Concrete Aggregate

D. H. Fuller, of the Bureau of Standards, spoke on testing of clay for light-weight concrete aggregate. Tests have been made on clays intended to produce, when fired, a light vesicular mass, suitable for concrete work. Such clays must be hard but not overfired, containing a large volume of pore space so that fresh specimens will float in water. The density of clay structure, the amount and character of carbon and the presence of sulphates and sulphides seem to affect the requirements. Materials which fail to float in salt solution of specific gravity 1.1 or which contain large cavities are unsuitable.

Determining Porosity of Clays

Edward W. Washburn and Frank Footit gave the results of experiments on the source of error in the methods of determining porosity of clays using the apparatus shown in Fig. 1.

(1) Place the cold test piece in a desiccator over 95 deg. sulphuric acid and allow it to remain till it reaches constant weight. This process may be hastened, if desired, by evacuating the desiccator.

(2) Place the weighed test piece in a vacuum vessel and evacuate the air until the manometer reads less than $P = \frac{AB}{100}$. Here B is the barometric reading and A is the percentage accuracy desired in the result. Then admit to the vacuum vessel enough air-free cold (the colder the better) distilled water to cover the test piece. Break the vacuum immediately, bring the water to room temperature, remove the test piece, wipe with a very damp towel and weigh. If the pump is not good enough to give the degree of vacuum indicated by the above equation, the vacuum vessel should be warmed until the water will boil under the vacuum obtained, and this boiling should be continued for about one hour.

A series of comparative experiments with water and paraffine, using the same test pieces, was carried out and the results were found to check within close range. Fig. 2 shows gain in weight with porosity test. A perfectly burned piece of dry clay is a better drying agent than calcium chloride or sulphuric acid.

Storing and Handling Raw Clays

T. W. Garve, in outlining a plant for the storing and handling of raw clays, emphasized the need of mechanical equipment in all such operations. Shales should be crushed before storing. Flat conveyors wear longest

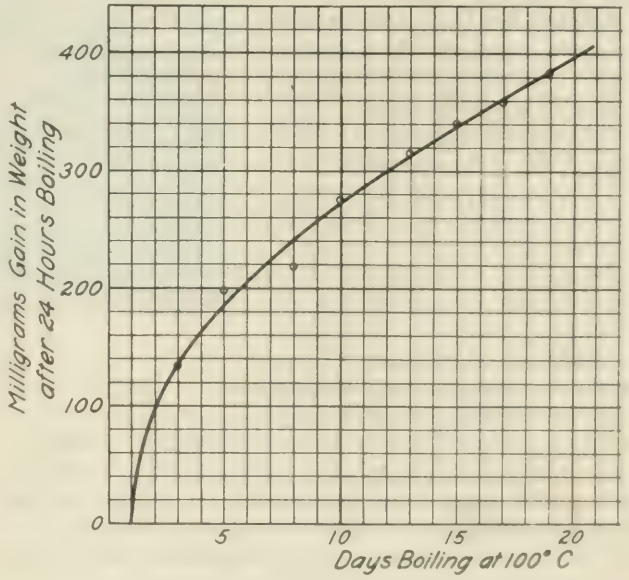

FIG. 2. GAIN IN WEIGHT—POROSITY TEST

and belt speed should be about 125 ft. per min. Details of machinery layout and buildings must conform to good mechanical and architectural practice.

Cobalt Oxide

N. B. Davis read a paper on cobalt oxide. Its use as a coloring matter in ceramics dates back to the early Chinese. The world supply for many years came from the cobalt-silver deposits of Saxony, and later from Missouri and Canada. Annual consumption in the United States amounts to 240,000 lb., most of which was used for ceramic ware. This is now being shared with the steel industry and chemical processes for drying the soya bean.

Other papers given were:

"Theory and Practice of Fractional Calcination of the Dolomites," by G. A. Bole and George Blumenthal.

"Experiments in Dead Burning Dolomite and Magnesite," H. G. Schurecht.

"Combustible Matter in the Chicago Clay," A. Malinovsky.

"A Direct Reading Overflow Volumeter," H. G. Schurecht.

"The Grain Sizes of Clays and the Relationship of the Grain Sizes of Certain Clays to Plasticity and Service," R. Thiessen and R. B. Gilmore.

"Fused Artificial Sillimanite," A. Malinovsky.

"Effect of Oxidation and Reduction on the Fusibility of Iron Oxide-Silica Mixtures," W. H. Reid.

"Further Study of MgO-Al_2O_3-SiO_2 Mixture, A. S. Watts.

"Methods of Testing Sagger Mixtures," S. C. Linbarger and C. F. Geiger.

"Waste Heat Drier Construction," E. Roddewig.

"Experiments With Aventurine Glazes," H. G. Schurecht.

"Some Luster Pottery Decorations," R. T. Watkins.

"Cost of Materials vs. Final Cost of Fired Pottery and Glass," George F. Hasslacher.

"Drying," William W. Wilkins.

Enamels Division

Papers in this division were accompanied by interesting discussions which evidenced the fact that the development has been slow owing to research being carried on by independent investigators. Considerable difference of opinion exists on important phases. The new subjects taken up were:

"Electric Cleaning of Metals for Enameling Purposes," W. C. Lindemann.

"Fish-scaling," J. B. Shaw.

"Fish-scaling of Gray Ware Enamels," R. R. Danielson.

"Cause of Fish-scaling in Enamels," R. C. Charron.

"Relative Action of Acids on Enamel—IV," E. P. Poste.

"Notes on Mottling of Enamels," R. C. Charron.

"Some Relation of Composition to Solubility of Enamels in Acid," H. F. Staley.

"Acid-Proof of Cast-Iron Enamel," H. F. Staley.

The last paper, covering a series of tests which are still under way, showed that the best oxides for acid-proof enamel as tested in a 20 per cent solution of HCl are SiO_2, BaO, PbO and Al_2O_3. The poorest results were obtained with ZnO, CaO, MgO, B_2O_3 and Na_2O.

Glass Division

H. L. Dixon, an old-time glass maker of forty-three years' service in the industry, delivered an inspiring address before this division under the subject, "Ancient and Modern Methods of Glass Manufacture. He told how the business, starting in Pennsylvania in 1843, migrated through Ohio, Indiana and Kansas following the development of natural gas properties. There have been losses extending over many years because there were no chemists on the job. Expensive materials were imported and glass makers produced their own refractories. Every factory should have a chemist. Science means so much to the business. A chemical education is necessary to the glass manufacturer's success at the present time. But the graduate must not make the mistake of analyzing everyone he meets by chemical equation. He should put on the undershirt, overalls and old hat and, going into the factory, win the confidence of the practical man, exchanging ideas with him. Colleges should teach the equality of the two types.

The word "can't" has been stricken from the vocabulary of the glass industry. Large things are ahead. The electric furnace in glass melting is the next step.

Other unpublished papers were given and discussed as follows:

"Glass Sand Resources of Pennsylvania," Charles R. Fettke.

"The Present Glass Situation," S. W. Stratton.

"Producer Gas as Fuel for the Glass Industry."

"The Art of Pot Making," Charles O. Grafton.

"Study of Some Glass Pot Clays," D. H. Fuller.

"Note on Porcelain Glass Pot Mixtures," D. H. Fuller.

"The Relation Between Refractivity and Chemical Composition in Optical Glasses," F. E. Wright.

"A Practical Test for the Resistance of Optical Glass to Weathering," F. R. Bichowsky.

"A Method of Determining Thermal Expansion of Glass," C. C. Rand.

"Note on the Mechanics of the Weathering of Glass," F. R. Bichowsky.

"The Annealing of Glass," L. H. Adams and E. D. Williamson.

"The Composition of Lead Glasses," R. J. Montgomery.

Measuring Viscosity of Pot-Made Glass

E. W. Washburn submitted a factory method for measuring the viscosity of pot-made glass during the process of manufacture. This includes the introduction of thermocouple into stirrer as shown in Fig. 3.

Refractories Division

D. W. Ross offered notes on silica brick. Not many careful studies have been made on the combined effects of thermal expansion as it occurs in the crowns of industrial furnaces. Study made on a bottle-glass

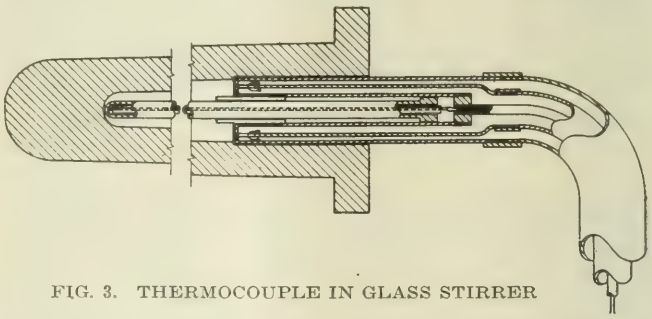

FIG. 3. THERMOCOUPLE IN GLASS STIRRER

furnace over a period of years led to the conclusions that (1) great care is necessary in heating up a new crown; (2) after eighteen months a crown can be slowly cooled without disruption; (3) a reheating of the cooled furnace gives less trouble, as the expansion is about one-half as great as during the initial heat; and (4) when crown is cooled after eighteen months' service the zone of weakness is found midway between the inside and outside of the crown.

Design of a Firebrick Plant

R. H. Minton's paper on the design of a firebrick plant was of especial interest to the manufacturers of refractories. In designing the process it should be

made as automatic as possible, compactly arranged and involve efficient burning. Complete layout was given, showing three wet pans, three rotary driers and three dry pans.

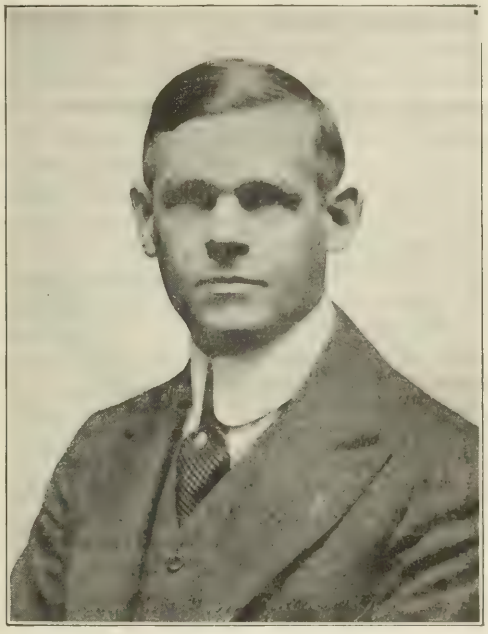
Sillimanite Development

A. S. Watts offered a possible explanation of failure under load at high temperatures as displayed by fireclay refractories. A peculiar combination of facts discovered over a period of years points to sillimanite development in the following points:

(1) Sillimanite is known to develop at about the temperature of observed failure.

(2) The sillimanite development through molecular rearrangement and not by crystallization out of solution would occur during the heating up process and does not require any definite period of exposure to the elevated temperature.

(3) The hard burning of the refractory prior to test could cause the sillimanite rearrangement in the mass and thus reduce the amount of strain due to sillimanite development at the time of test. This explanation of the improvement due to hard burning is at least as logical as that the advanced solution of the flint clay gave it strength under high temperatures.



R. H. MINTON
President, 1920, American Ceramic Society

(4) The increase of SiO_2 as a means of improving strength at elevated temperature can be explained as also reducing the Al_2O_3 content to a point at which the development of sillimanite is very small or nil, and thus its weakening influence is not displayed.

(5) The low sillimanite development in ball clays may explain their freedom from weakness at temperatures where fireclays and pure kaolins fail, and as they have no associated material of greater refractoriness which they can absorb, the explanation of their superior behavior must lie within themselves.

Other papers under this division were as follows:

"Mica Schists as Refractories," J. S. Hibbs.

"Conductivity of Refractories and Methods of Testing Conductivity," by S. F. Walton and F. H. Riddle.

"Magnesite Refractories," J. S. McDowell and R. M. Howe.

"Tests on a California Refractory Clay," H. W. Douda.

"Testing Refractories," F. A. Harvey.

"Refractory Clays of Missouri," I. A. Krusen.

"Behavior of Firebrick in Malleable Furnace Bungs," H. G. Schurecht.

"Note on the Load Behavior of Aluminous Refractories," A. V. Bleininger.

"An Industrial Laboratory for Research in Ceramics With Note on the Construction of a Novel Testing Furnace," S. F. Walton.

"Siliceous Sagger Mixtures," M. R. Hornung.

"Behavior of Bond Clays in Graphitic Crucibles Under Brass and Steel Melting Practices," R. T. Stull.

"Use of the Microscope in Crucible Making," R. Thiessen and R. B. Gilmore.

"The Fusibility of Mixtures of Graphite Ash and Bond Clays," R. N. Long.

"A Rapid and Approximate Method for Determining the Melting Point of a System Composed of Highly Refractory Materials," E. W. Washburn.

Terra Cotta Division

R. L. Clare and D. F. Albery have investigated the effect of variation in the size of the grog in terra cotta bodies, and results showed clearly that if the terra cotta is to be kept uniform in its physical properties the grog size must be controlled. To accomplish this the grog must be specially prepared and ground under stated conditions. It must be selected and burned under specifications. A central plant operating for several companies was suggested. The extra cost would be more than offset by advantages resulting.

R. H. Minton in searching for a substitute for tin oxide found that little work has been done outside the enameled ware field. Results showed that tin oxide is the best opacifier, although "terrar" and zirconium oxide offer possibilities. Zinc oxide is of great assistance in producing capacity when used with tin oxide. Barium also exerts a marked influence, while a combination of barium and zinc has more effect than the clay content, giving more favorable opacity. Antimony oxide and "leukonin" are cheaper than tin where applicable. Zirconium has proved to be the best substitute, but it is too expensive.

Research on Vermilion Colors

Charles F. Binns and Frobisher Lyttle in research on vermilion colors made two glazes, one with 20 per cent commercial yellow oxide of uranium content and the other using 37 per cent. The first gave a bright vermilion color. Some difficulty has been experienced in protecting uranium oxide from reducing influences in firing, but with complete oxidation these colors seem to be commercially possible.

J. D. Whitmer presented the results of a glaze study involving some interesting colors produced by nickel oxide which demonstrated that grays are obtained from nickel oxide in the presence of magnesium oxide.

Other papers presented and discussed were:

"The Effect of the Size of Grog Particle in a Terra Cotta Body," H. E. Davis.

"Discussion of Humidity Drying of Terra Cotta," B. S. Radcliffe.

"Satisfactory Method of Using Barium Hydrate in Place of Barium Carbonate to Take Care of Soluble Salts in Terra Cotta Bodies," M. E. Gates.

"Some Data on the Composition of Kiln Gases and Their Effect on Terra Cotta Glaze and Colors," F. B. Ortman.

"Discussion of Spalling of Enamel Terra Cotta After Erection in Building," F. B. Ortman.

"The Effect of Glaze Composition on the Crazing of Terra Cotta," E. C. Hill.

White Ware, Porcelain, Etc.

A. S. Watts presented the draft of a complete set of specifications for flint and another for feldspar under the following headings:

1. Sampling.
2. Chemical composition.
3. Physical properties and tests.
   (a) Color.
   (b) Fineness of grain.
   (c) Moisture content.
   (d) Fusion behavior.
4. Rejection.

Substitute for German Clays

Jerome Alexander outlined preliminary ultramicroscopic examinations of clays during the war in determining the proper American substitutes for German clays, which showed that a thorough study of clays along the lines of colloid-chemical principles and analysis will throw much light upon many obscure phenomena met with by clay users. These factors extend their influence not only to the formative part of the ceramic processes, but to the subsequent drying, baking and firing, and the effects are traceable to the zone of actual fusion.

Tests on Rate of Vitrification

R. F. Sherwood gave the results of tests on the rate of vitrification of porcelain molded under different conditions. The initial structure of a clay body governs the rate of contraction and vitrification. A comparison was made to show the difference in the rate of vitrification of one and the same body molded by hand pressing in the plastic state, by casting and by dry pressing at different pressures and finally firing simultaneously in the same kiln, giving identical heat treatment. The cast gave the most dense body and the plastically molded body had the most rapid rate of vitrification.

Other offerings were as follows:

"The Use of Domestic Kaolins in the Manufacture of White Ware Pottery," A. V. Bleininger and W. W. McDanel.

"A Possible Explanation of the Differences in the Behavior of Potter's Flint and Ground Quartz in Pottery Bodies and Glazes," E. W. Washburn.

"Tests of Commercial Samples of Feldspar and Flint," B. E. Sockman.

"The Effect of Wet Grinding, Screening, and Electrolytes on Clays of Low Plasticity," H. W. Douda.

"Elutriation Tests on American Kaolins," H. G. Schurecht.

"The Effect of Aluminum Chloride Upon the Plasticity of Kaolins," H. P. Reinecker and J. S. George.

"The Effect of the Method of Preparation on the Viscosity of a Casting Slip," V. S. Schory.

"Some Problems in the Manufacture of Sanitary Porcelain," Samuel Bedson.

"Structure of Porcelains," H. Spurrier.

"Note on Zirconia Porcelain," A. V. Bleininger.

"The Solubility of Some White Ware Glaze Fritts," George Blumenthal, Jr.

Kilns

The symposium on tunnel kilns developed little criticism of the tunnel kiln by the users of periodic kilns, but rather resulted in an argument between tunnel kiln manufacturers as to the relative merits of the direct-fired and the muffle-fired types. The chief advantages of the latter are the economy of fuel effected, better control in firing, convenient handling of materials, elimination of saggers, and smaller maintenance cost due to continuous heat. On the other hand, there is a question of less capacity and more floor space. The coming year should develop some real data for comparative figures.

Entertainment Features

The smoker held on Monday evening proved a marked success due to the feature event, a farce presented by the New York Student Section, entitled, "A Day in the Secretary's Office." The adaption of new lines to well known tunes was welcomed enthusiastically by the audience. The Ceramic Engineers' Song was especially applauded as to the last verse, which runs:

> Oh, we're Ceramic Engineers,
> We're not so very neat,
> We never change our underwear,
> We never wash our feet,
> We wear our collars and cuffs for months,
> With grime and dirt they're smeared,
> Oh, we're the very scum of the earth,
> Ceramic Engineers.

The banquet under the skillful direction of Francis Walker, Sr., was most pleasurable. Mr. Cattell, the Philadelphia statistician, was there with his usual greetings to which everyone looks forward at these conventions. He said "au revoir" meant "goodby" in France, but "carbolic acid" meant "goodby" in every country. He finished with a truly Cattell appeal for "Americanism." The applause continued with everyone standing for many minutes. Calvin O. Althaus delivered an eloquent address.

The whole affair was just informal enough to carry the right appeal.

The Philadelphia Section

The work of the local section in providing everything necessary for convenience and comfort of the visitors received a unanimous vote of thanks at the business meeting. Trips were made to places of interest and industrial plants on Thursday.

Electrochemists and Electrical Engineers to Meet Jointly in Boston

Plans for the joint session of the American Electrochemical Society and the American Institute of Electrical Engineers at Boston, April 8, 9 and 10, are progressing so favorably that there is every promise of an unusually good meeting. The symposium on electrically-produced alloys will be opened by H. E. Howe, with a paper on "Fundamental Problems in Alloys Research." The manufacture of ferro-alloys in general will be discussed in two papers by R. J. Anderson and C. B. Gibson. Other special alloys on which papers have been prepared are ferrovanadium by B. D. Saklatwalla; ferrosilicon by F. A. Raven; nickelchrome by W. B. Driver, Jr.; cobaltchrome by Ellwood Haynes; ferromanganese by E. S. Bardwell and high-speed steel in the electric furnace by R. C. McKenna.

The session on power requirements for electrochemical industries will be addressed by H. A. Winne, C. A. Winder and John A. Seede. Other papers of technical importance are "Nitrogen Fixation by the Silent Electric Discharge," by C. F. Harding, and "Magnetic Properties of Iron-Nickel Alloys," by T. D. Yensen. There will also be a symposium on colloids.

Political and Commercial Control of the Nitrogen Resources of the World—I

A General Review of the Sources of Nitrogen: Atmospheric, Nitrate Ore, Organic and in Carboniferous Deposits, With a Description of the General Aspects of the Control of Nitrogen Resources in Normal and War Times

By CHESTER G. GILBERT*

PLANT life requires nitrogen, and gets it in the normal cycle of events. But when the occasion calls for stimulating the growth of plant life by feeding —by soil fertilization, in other words—nitrogen in available form is indispensable. Further down along the channels of food supply it exercises another and equally important function in providing the chemical around which the modern practice of refrigeration is built. Likewise, the chemistry of explosives is basically the chemistry of nitrogen compounds. Nor is this all, for chemical operations in general, hence research and industrial chemistry in general, involve the employment of nitrogen compounds. Such, in brief, is its social status. On each of three major counts—the interests of food production, of food distribution, and of national defense—it is indispensable; and of no less consequence is the retinue of less conspicuous agencies serving the interest of chemistry at every turn.

The development of fixed nitrogen sources is conditioned by three simple chemical facts. With these three simple facts in mind the rest follows largely as a matter of inference. They are:

1. That under all ordinary conditions of temperature and pressure, free nitrogen is a gas.
2. That it is extremely inert and indisposed to participate with other elements in the formation of chemical compounds.
3. That such combinations, when they do occur, are characteristically soluble.

In consequence of these three governing principles, along with its relationship to organic matter as alluded to above, nitrogen has four habits of occurrence worth considering as at least potential sources of supply; namely, atmospheric nitrogen, nitrate ore deposits, organic nitrogen and nitrogen in carboniferous deposits.

Atmospheric Nitrogen

Being indisposed to participate in chemical combinations, nitrogen in the course of world evolution was left largely to itself; and since in the free state it is normally gaseous, it established its home in the atmosphere. Thus it comes about that the atmosphere today is approximately four-fifths nitrogen gas, and after all is said and done the atmosphere is bound to constitute the great source to which we must turn for our supplies. With a source so boundlessly ever-present, the question of supply at first glance looks simple enough. But atmospheric nitrogen, it must be remembered, is nitrogen uncombined, and the demand is not for nitrogen itself but for nitrogen-bearing compounds. Once in a state of combination, it may remain so indefinitely, and the form of combination may be changed more or less readily to suit the demand. Before it can be put to use, however, it must be induced to surrender its gaseous freedom and affix itself in some such state of combination. The free nitrogen must become fixed nitrogen—hence the terms fixed nitrogen, nitrogen fixation and the like in common use. Toward this end it must be induced to do what it has not seen fit to do of its own accord, and the very trait of aloofness responsible for the inexhaustible resources of atmospheric nitrogen stands as an obstacle opposing their utilization. The obstacle has not proved insuperable, as will appear later; but it is sufficiently a source of trouble even to this day, so that the fixed-nitrogen situation may with peculiar appropriateness be characterized as distinctly in the air.

Nitrate Ore Deposits

The disposition on the part of nitrogen to take up its abode in the atmosphere has an obvious result in minimizing the development of mineral nitrates. Atmospheric nitrogen is not entirely stagnant, however. Natural processes are constantly at work effecting substantial fixation. The processes are not obtrusively energetic, as in the case of atmospheric oxygen, whose fixation processes constitute the ever-present phenomena of oxidation. Still in various ways, the most prominent among which is undoubtedly a form of bacterial action, nitrification and the building up of nitrate minerals everywhere in the soil goes quietly forward, and their concentration in ore deposits of more or less plentiful occurrence is thus to be looked for in the natural course of geologic events.

Development of Nitrate Ore Deposits

In attempting to trace their further course, however, we are confronted at the outset by the principle of solubility. The nitrate minerals are in the nature of soluble salts. They leach from the immediate environment in which they form, just as do the soluble minerals in general. Mostly these latter are carried in solution to the ocean, adding themselves to its salinity; but under exceptional conditions of topography where the drainage feeds into land-locked basins, the water finds itself entrapped with no avenue of escape except through evaporation. Here the salts accumulate, become concentrated, and finally give rise to deposits. This, in outline, is the course set for the soluble mineral salts as a class, and it is along this course that we must expect to trace the development of nitrate ore deposits.

Dissociation of Nitrogen Compounds

But the ocean with its 3½ per cent of salinity has only traces of nitrate minerals; and the same is true for the waters of land-locked basins, in all the various stages of concentration. Their solubility is such that they cannot

have escaped in substantial form along the way. There is only one inference to be drawn. Evidently the inherent trait of aloofness is not lost to nitrogen when it does combine. The compounds do not survive for any length of time, but suffer dissociation, releasing their nitrogen and returning it to the atmosphere even as other processes are slowly withdrawing it therefrom.

With this the eternal cycle is closed for nitrogen, and closed without apparent provision for any considerable sidetracking such as would be required in the building up of ore deposits.

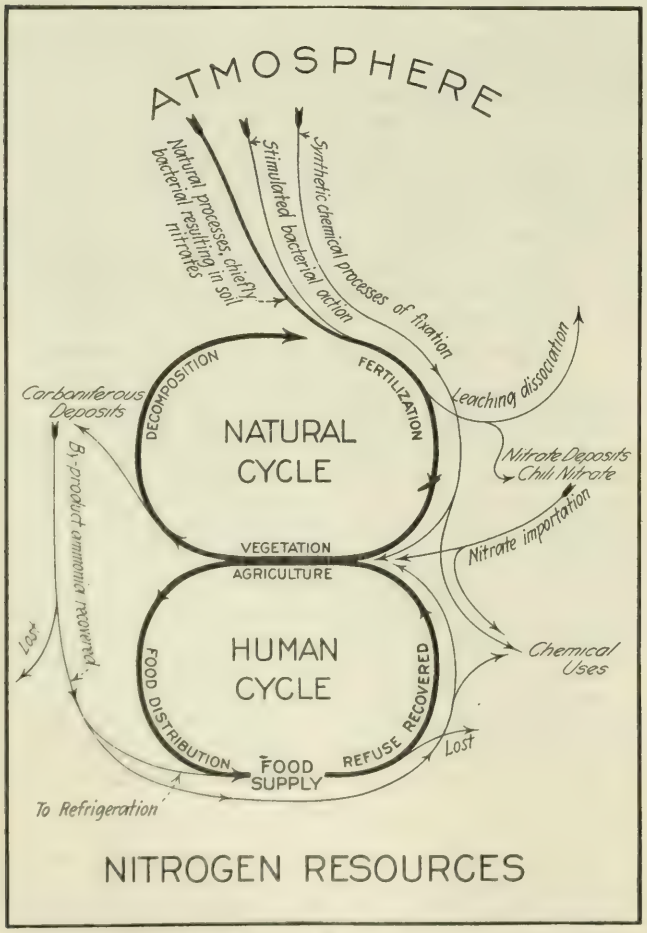

FIG. 1. GRAPH OF THE NITROGEN SITUATION

So much for the rule; now as to the exceptions. Mostly they are of minor consequence. Pockety enrichments in the soil are common. Accumulations tend to build up in caves and may even grow to be of consequence in a small way, as during the Civil War when they helped materially toward relieving the nitrogen troubles of the blockaded Confederacy. In arid country, too, they not infrequently assume sufficient prominence to be of interest especially at the hands of the promoter. Finally, there are the Chilean nitrate fields, which far from being of minor consequence, go to the other extreme in catering to the needs of the entire world. These occurrences, especially the last named, have served to keep alive the hope that others of economic importance await discovery. The Chilean deposits alone among them all deserve more than passing notice.

Origin of the Chilean Nitrate Deposits

The origin of these deposits is veiled in uncertainty. Just why or how the natural forces, which elsewhere as a matter of universal observation have been seen to oppose both the formation of nitrogen salts and the accumulation of such as do manage to form, should have failed in this particular instance remains wholly conjectural. A conclusive explanation would be of the utmost value in determining the likelihood of similar occurrences elsewhere. But none has been forthcoming, and nothing is to be gained to the present purpose from stopping to inquire into the plausibility of the various attempts that have been made.

Confronting us on the one hand are the evidences of a nitrogen cycle established, seemingly, without affording any visible loophole of opportunity for the accumulation of extensive deposits; on the other hand stands the bare fact of enormous deposition. This fact of existence unquestionably carries with it the possibility of duplication elsewhere. However, the fact of occurrence merely suggests the possibility, but does not determine the chances of recurrence. These are recorded in the prevalence of the conditions requisite to extensive deposition. In the case of nitrogen they are unique beyond comprehension, and the prospect of recurrence is to precisely the same degree unlikely. Accordingly, to all practical purposes, a review of the world's nitrate ore deposits, both real and potential, resolves itself down to a review of the Chilean occurrence.

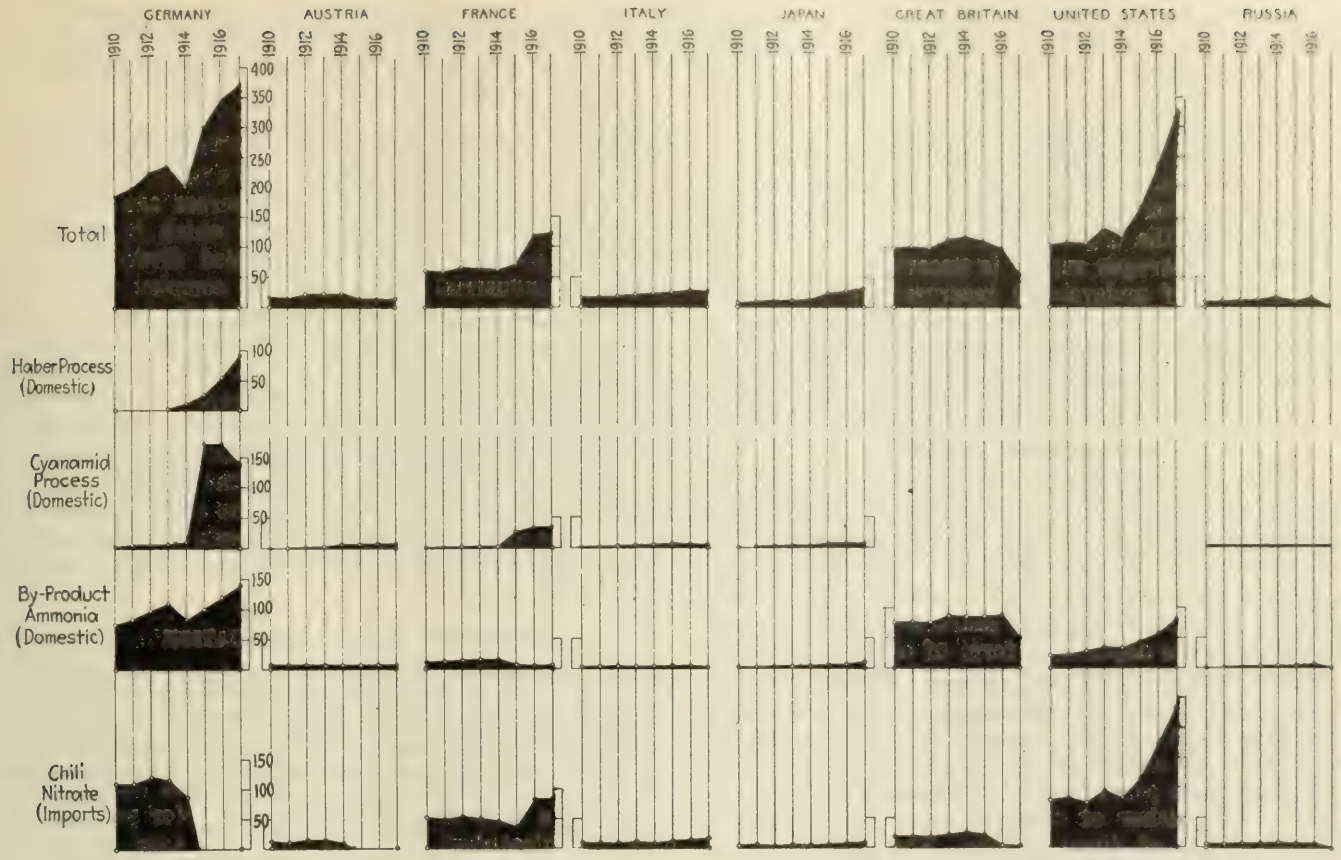

FIG. 2. WAR-TIME DEVELOPMENTS IN THE PRODUCTION OF NITROGEN—FIGURES IN THOUSAND TONS

The Chilean nitrate fields lie in the arid valley basin to the east of the lofty coast range and just south of the present Peruvian boundary line. They do not occur as a single expansive area of deposition, but as deposits scattered here and there along the desert land at the bases of the mountain slopes. The formation consists of a conglomerate or breccia of rock material from the adjacent slopes cemented with a mixture of soluble salts in which sodium chloride, common salt, is the dominant member, with sodium nitrate ranking second. The formation is called caliche. It lies for the most part just below the surface of the ground and varies from a few feet to many feet in thickness. Only in scattered patches is the caliche high enough in content of sodium nitrate to warrant treatment. These patches are sought out and excavated, and the picked ore is loaded in carts which haul it to the extraction plant for treatment. Here the soluble salts as a whole are extracted in solution, and the nitrate in turn is segregated from the other salts by crystallization. Aside from haulage, hand labor is used throughout.

The caliche regarded as worth treating contains not less than 10 per cent and ranges up to 25 per cent and over, with an average of around 18 per cent. The product marketed is of two general grades—the ordinary, listed as 95 per cent nitrate, and the refined, a guaranteed 96 per cent nitrate low in sodium chloride. The deposits have been worked more or less consistently and with steadily increasing output since about 1830. Their importance in the scheme of nitrogen supply may be gathered from Table I and Figs. 2, 3 and 4.

Organic Nitrogen

Another source of fixed nitrogen grows out of its relationship to life processes, and is consequent on the very requirements of organized society which earlier it is called upon to assist in meeting. In other words, fixed nitrogen participates in the material cycle of life. It enters into the material demands of life for food, and it is yielded up among the material discards available to absorption. All manner of residuum, animal and vegetable alike, affords at least a potential source of fixed-nitrogen supply. Some of these are in service; others for one reason or another are not. Prominent among those in the former class are animal excreta, the so-called tankage from animal-rendering plants, slaughter-house refuse, fish scrap, and vegetable product refinery refuse. Most prominent among those still largely potential are sewage and garbage disposal.

Importance of Organic Nitrogen

The nitrogen from these organic sources does not appear on the market as such. Instead, the products enter in bulk into the make-up of fertilizer. They are of miscellaneous character, and only part of what is contributed collects to pass through industrial channels where its flow may be measured. The industrial flow goes on record and the records are available, but even here the nitrogen content has never been systematically computed, so the record is inadequate. For the rest, the portion that does not reach the channels of industry, there is nothing whatever in the way of data to go by.

Taken all in all, then, the significance of the organic nitrogen resources is largely conjectural. This is unfortunate. The production is so diversified and distributive that anything like exactitude of statistical data would be impossible of compilation, but there is no justification in this for the assumption that nothing is to be gained. Approximate figures covering the use of organic nitrogen would be of value in various connections, as in the interests of intelligent allocation in times of nitrogen shortage, as helping to determine the

extent to which the growing demands of agriculture incident to the growth of population may be discounted from the consequent expansion of scavenging opportunity, or as affording a basis for estimating the very considerable influence of motorization toward increasing the demand for chemically prepared fertilizers.

As things stand, all such questions of relationship lead only to profitless speculation. Even the relative importance of the organic sources as a whole in the economics of nitrogen supply is uncertain. What they have to offer of undeveloped reserves now taking the form of wasteful sanitation procedure will be taken up later. Under existing conditions, it is probably fair to assume that 40 to 50 per cent of the nitrogen normally put to use in the United States is organically associated.

Carboniferous Deposits

Nitrogen in its organic relationships is bound up with carbon, of which organic matter is largely composed, and the bond between the two is entirely disestablished only as the carbon itself loses its substantial form through oxidation. In consequence of this enduring alliance, nitrogen is characteristically present in carboniferous deposits, a form of occurrence giving rise to still another, a fourth type of nitrogen resource. Coal and oil shale loom up as the outstanding representatives of this class. In each, the nitrogen content is variable, but amounts to 1 per cent or over.

With so low a percentage of nitrogen, it goes without saying that neither of these is to be regarded as a possible source of direct supply. The cost would be prohibitive, even under the stress of the most extreme emergency. The nitrogen in a coal bed or an oil-shale formation is as worthless as the iron in any ordinary rock. But coal has other uses, and so has oil shale, or at least will shortly. The nitrogen does not have to be extracted; it gets released incidentally, and when its release is effected under conditions that prevent its escape, the result is a productive nitrogen resource. The nitrogen from this type of resource is in the form of ammonia, the relative importance of which is shown in Table I and Figs. 2, 3 and 4.

General Aspects of Control of Nitrogen Resources

The nitrogen resource situation as a whole is represented graphically in Fig. 1. Its sources are animal, vegetable, mineral and atmospheric, which is to say, universal, and out of this unparalleled diversity has grown an industrial development as complex as it is diversified, and, incidentally, in view of its bearing on food and munitions supply, as important as it is complex. The situation at best can be but imperfectly grasped, for it has been but inadequately studied. In transgressing all set rules of resource occurrence, it transgresses the limits set for organized investigation. Geologists have studied one phase of the situation, electrochemists another, sanitation experts another, and so on; and the various commercial interests involved have seen to the giving of publicity where publicity would do the most good.

Composite Economic Situation

An investigation working on the basis of geology alone cannot cope with the situation; neither can one on the basis of technology alone; nor one on the basis of organic chemistry, or bacteriology alone; nor yet one prepared to employ any or all of these means but only with a view to some special end. Nor yet again does the discordant grinding of many axes make a noise from which it is possible to gather an adequate comprehension. The nitrogen situation has been inadequately treated because it has been inadequately studied. It has been studied piecemeal, always through the medium of limited means or with some special end in view.

It is not a series of technical problems in geology, in

(1) War-time expansion for munitions manufacture. (2) Field of competitive opportunity indicated for Chilean nitrate, air nitrate fixation, improved coal fuel practice, shale-oil ammonia, bacterial fixation, imposed sanitation, etc. (3) Field of opportunity reserved to coke-oven recovery. (4) Developments indicated for coke-oven recovery.

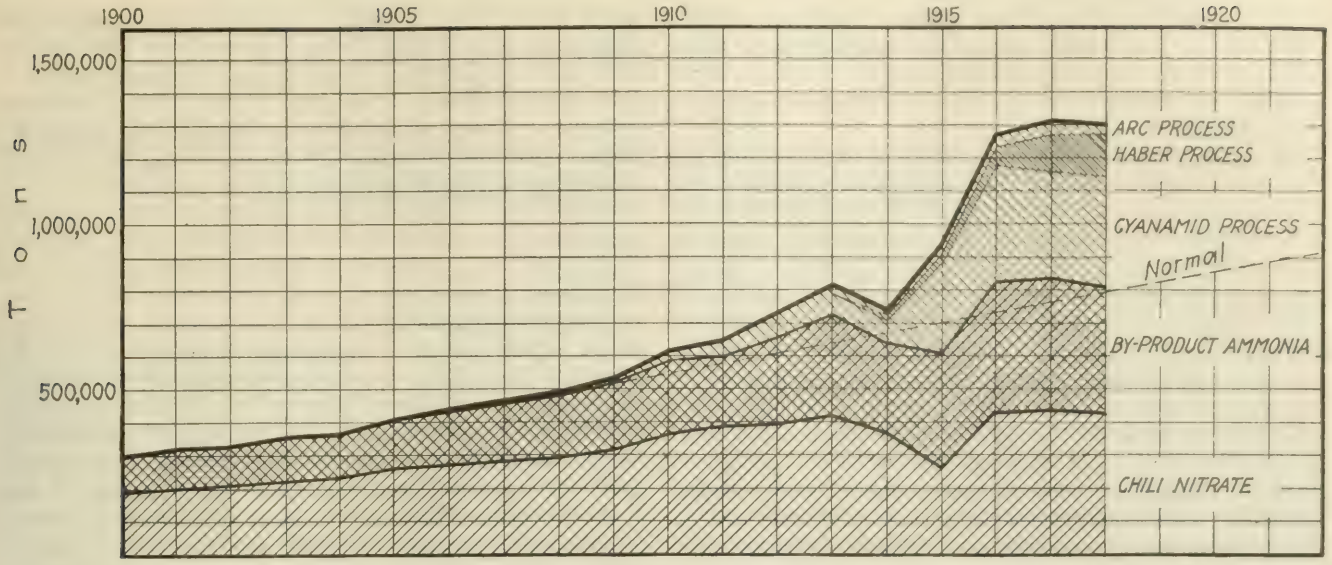

FIG. 4. NITROGEN DEVELOPMENTS FOR THE WORLD, 1900-1918

bacteriology, in fixation, in munitions supply, and the like. It has to do with a composite economic structure building for the dependence of society in peace and war alike. Until treated as such, the needs of the situation are bound to be inadequately met and its control a matter of perilous uncertainty. The present discussion makes no pretense of supplying this deficiency or of doing much of anything more than to show the extent to which it exists.

Control of Nitrogen Resources

Fig. 1 is designed to show not so much the scope of the resources as their composite functioning in the system of nitrogen supply. The influence of geography in the control of resources so universally available is bound to be subordinate. True, it enables Chile to exercise monopolistic control over the mineral nitrate supply, but it leaves the way open for the development of others; and while acknowledging the fullness of our dependence as shown in Table I and Figs. 2 and 3, we must not lose sight of the fact that it is so not of necessity but because we have been content to leave it so rather than undertake to develop supplies of our own.

So, too, with political control; what is gained in one direction is, potentially at least, offset by the possibilities opening up in others. Control of the sea gives a control over the mineral nitrate supply as absolute as that in Chile's territorial monopoly. Yet in the recent great war Germany, with her shipping obliterated at the outset, was not made to suffer materially from a nitrogen shortage. Britain's supremacy of the sea went for naught. In the years before the war the force due in season to exercise control over the nitrate supply served only to stimulate the development of domestic potentialities, with the result that when the test came Germany's proved actually to be the more advantageous equipment.

Control over the nitrogen resources themselves is impossible. They are too universally available. Their only susceptibility to control is in the shaping of their development. This is too important a matter to be disregarded with impunity and left to develop without guidance. The modern nation that does so courts the irrepressible disaster of a nation at war but bereft of the means not only of waging war but of maintaining a food supply as well.

From Fig. 2 may be gathered the quality of attention given the matter of domestic supply by the different nations immediately before and during the war.

Germany, it will be observed, heeded the call to give the matter special attention well before the war and had an independent system of supply developed in readiness drawing upon the atmosphere and coal product nitrogen, with the results already chronicled.

Great Britain did not ignore the importance of nitrogen, but placed reliance on her supremacy of the sea and paid little or no attention to shaping the course of developments. Nor did its importance go unheeded elsewhere abroad, and the foothold gained for fixation in France, Italy, Austria, Russia and Japan was, it is safe to say, not wholly automatic.

The United States alone among the great nations up to the outbreak of hostilities in Europe in 1914 neglected to take any special precautions whatever.

War's Special Requirements for Nitrogen

The war, when it came, far exceeded all expectations as to magnitude, and so in consequence did the demand for specially developed nitrogen supplies. To meet the emergency some could be deflected from agricultural channels, but nothing like what was required, for food was just as important as munitions. The organic sources offered no help. Rather they were a hindrance; for organic nitrogen, broadly speaking, comes as a by-product of sanitation, and as such develops as the outgrowth of civilization's refinements. There was a measurable response from the carboniferous sources, but these could not be made to meet the emergency, for, being of byproduct order, the supply is determined not in response to the demand for nitrogen but for the major products. Dependence on the native mineral source in Chile was out of the question, or at least precarious for any country except Great Britain. Accordingly, of the four great sources it remained for atmospheric nitrogen to meet the emergency. Thus, the war, in bringing the nitrogen situation emphatically to the fore, communicated practically the whole weight of its tremendous impetus to development in the one direction of fixation. The result is shown in Fig. 4.

Roused by the nightmare of war in 1914, even the United States awoke to the perils if not to the real needs of the domestic situation. It is a striking and

highly significant fact that despite the fundamental importance of nitrogen, the awakening found us absolutely without any formulated program of action, even military or agricultural, let alone anything of comprehensive economic scope.

A hysterical effort at improvizing a program ensued. We were not yet in the war, and public interest was just roused to the gullible stage. The opportunity for private pickings from public favors was too promising to go by the board. The only prospect opening up lay in the direction of fixation developments, and fixation in the hands of the promoter is one of the most appealing propositions imaginable. Its major requirements are nitrogen and power. With the former inexhaustibly present in the air and the latter inexhaustibly available in the wasting water powers of the country, nothing, it would seem, could offer greater promise. Add to this the reflection that cheap nitrogen means cheap fertilizer, and cheap fertilizer means lowered cost of foodstuffs, and the proposition broadcasted over the country is complete.

Out of the confusion of interests, public, political, and private, a program was finally evolved following our entry into the war calling for the erection of a series of fixation plants with an aggregate producing capacity of around 85,000 tons of fixed nitrogen annually. For a detailed description of these plants the reader must be referred in the interests of brevity to the Bibligraphy. For the present it must suffice that the war ended before any of these had reached the producing stage, and the United States, like Great Britain, depended on imports.

Influence of War on the Development of a Nitrogen Industry

Fig. 2 shows the influence of the war in the development of nitrogen distributively among the countries concerned. The Scandinavian developments, while actuated from wholly commercial motives, were so largely influenced by the politically stimulated market that they may well enough be included in that general class of politically controlled developments. The same is true for the neutral countries in general.

Fig. 4, based on the best information obtainable, is designed to show the collective influence of the war in contributing to the world's supply. Organic nitrogen is disregarded both because it involves too many uncertanties and because the war-time emphasis was all in the direction of chemical nitrogen. The data in Fig. 2 take into consideration only the actual production and leave out what was in process of construction when the war ended. Accordingly, while in one respect Fig. 2 overrates the effect of the war by including strictly commercial operations that very possibly might have transpired anyway, in another it underrates the situation by disregarding developments like those in this country. The best that can be done is to consider these as balancing each other, which, all things considered, is probably fair enough for all practical purposes. Taken on this basis, the net effect of the war, it will be observed, was to swell the production of fixed nitrogen about 40 or 50 per cent above the figures indicated for the normal rate of expansion.

Peace-Time Needs of Nitrogen

Thus the war-time shortage was made up; but all this is history. Now that the war is over, the question arises as to whether the world is due to face the situation in reverse. In making ready for war, and finally in meeting its demands, has the world been building up a 50 per cent overproduction beyond the needs of peace? Offhand, the answer would seem to be in the affirmative, but the question is not one that can be answered offhand. Agriculture is capable of absorbing an indefinite amount of nitrogen, and the war has wrought a lasting change in the agricultural situation. The changed agricultural conditions make room for much, perhaps for all, of the increment to nitrogen production. The development cannot be sustained, however, on its present arbitrary preferential basis of political expediency. Least of all can it be sustained on that basis in this country. Normally, we do not and cannot be made to think in terms of war. The reason is evident enough, and its recurrent force is already apparent. Distasteful as the fact may be in some of its extremes of application, the only rational procedure is to accept it and fashion our measures of economic preparedness so that the normal activities of peace will keep our economic forces exercised and in trim for the test of war. It was recognized all along before the war that without an assured source of nitrogen supply, our system of defense was hollow; but we succeeded in building up no means of supply in direct response to political needs. We managed to get comfortably started during the war, but it remains to be seen to what extent this artificially nourished development is fitted to withstand the bitter strife of competition ahead.

Part II, dealing with the commercial aspects of nitrogen control and recent developments and changes in practice will be published in our next issue.

Ample Supply of Chilean Nitrate Assured

Sufficient tonnage has been placed in the nitrate trade by the Shipping Board to insure an ample supply of Chilean nitrate to meet fertilizer demands during the coming season. Few deliveries will be made during March, but a sufficient number of ships has been allocated to insure large deliveries during April, May and June. The allocation of ships was arranged after a careful study of the situation by representatives of the Shipping Board and of the Bureau of Soils.

Bureau of Chemistry Appropriation

The total appropriation allowed the Bureau of Chemistry in the agricultural appropriation bill, as it passed the House, was $1,321,591., The general salary account totals $426,190. Other items forming a part of the appropriation are as follows: Biological investigation of food, $66,400; chemical investigations for other departments, $14,000; to carry into effect the provisions of the food and drug act, $579,361; naval stores investigation, $10,000; insecticide investigation, $20,000.

Metric System Bill

Hearings are to begin in the near future before the Committee on Coinage, Weights and Measures of the House of Representatives on a bill making the use of the metric system compulsory by the Government departments. The exact provisions of the bill have not been announced. Representative Vestal of Indiana, chairman of the committee, has been assisting in the drafting of the bill, but as yet the draft has not been perfected. Mr. Vestal states, however, that the bill will be introduced shortly.

The Requirements of Refined Copper

A Discussion of the Market Requirements of Refined Copper as to Electrical Conductivity, Pitch, Ductility, Casting and Dimension, Together With Notes as to the Effect of Analysis, Manipulation and Metallurgical Practice on These Characteristics

By LAWRENCE ADDICKS*

IN ORDER to satisfy market requirements, prime electrolytic copper wirebars and cakes must possess high electrical conductivity, sufficient ductility and physical soundness. From the refiner's point of view the product must also be free from commercial quantities of precious metals. Ingots are given a little more leeway in conductivity and relieved of restrictions as to soundness, inasmuch as they are intended for remelting.

This general subject may advantageously be discussed under the headings of conductivity, pitch, ductility, casting and dimensions.

Electrical Conductivity

It has come to be generally assumed that if a wirebar is a sound casting and a sample of the copper drawn into wire shows a satisfactory conductivity, the product may be accepted as prime electrolytic (or lake) copper. This assumption is not strictly true, as will be shown later, but inasmuch as the preparation of the sample of wire for testing in itself demonstrates within certain limits the ductility of the copper, as the test may be easily and quickly made and as no other test appears to be of general application, conductivity will probably remain as the chief criterion of commercial copper.

Impurities in copper may be divided into three groups as regards their effect upon conductivity: Those which are insoluble in copper, those which are partially soluble and those which are completely soluble—remembering that we are interested only in mixtures where copper enormously predominates.

The elements which are insoluble can evidently have but little effect upon the conductivity, inasmuch as the total quantity of any one impurity is always far below 0.1 per cent and the impurity itself has a certain specific conductivity.

The class which is partially soluble exerts a very marked depression on the conductivity, as such elements form low melting point alloys with copper which crystallize out as eutectics, forming a matrix surrounding crystals of copper like the mortar joints of a mosaic. This matrix may be quite bulky, as part of the copper is added to the quantity of impurity present.

The few elements, such as silver, that form solid solutions with copper have a relatively mild effect upon the conductivity, which is quite negligible in view of the small quantities present.

About fifteen years ago the writer conducted a systematic investigation into the relation between impurities and copper (*Transactions*, American Institute of Mining Engineers, vol. 36, p. 18). Each element in question was added in varying amounts to crucible melts of high-grade copper wire and the conductivity of an annealed sample of wire drawn from the cast compared with the assay of the same wire for the impurity added. The results of this work are grouped together in Fig. 1.

It will be noted at once that the elements which are known to make copper brittle, such as lead, bismuth and tellurium, have but slight effect upon the conductivity, while those which make excellent bronzes, such as phosphorus, aluminum and silicon, have caused a marked depression. It is difficult, however, to make any practical application of these results, because the presence of one impurity often neutralizes the effect of another, and copper which would be expected to be of indifferent quality based upon these figures may prove to be excellent. This is the reason that chemical analysis, apart from the difficulties attending the accurate determination of traces of impurities, has proved of little value in judging copper as compared with the more practical test of forging and drawing followed by a measurement of conductivity.

By common consent conductivity has come to be expressed in percentage of the value of 0.141729 international ohm at 0 deg. C. found by Matthiessen for a meter-gram of supposedly pure copper over fifty years

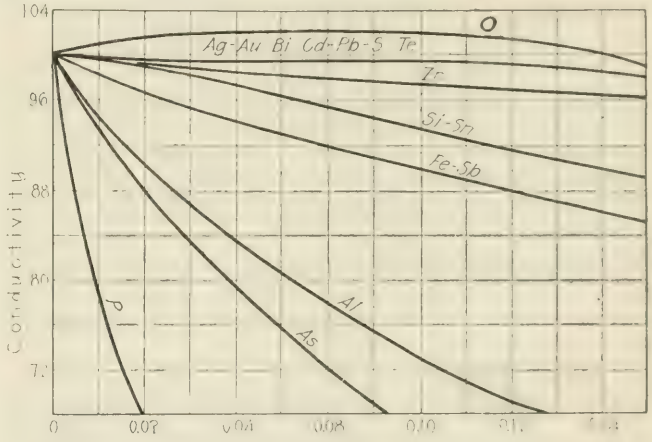

FIG. 1. EFFECT OF IMPURITIES ON CONDUCTIVITY

ago. The specifications of the American Society for Testing Materials have established a minimum requirement equivalent to 98.5 per cent for wirebars and cakes and 97.5 per cent for ingots, determinations being made upon annealed samples. Average copper on the market runs considerably higher than these figures, much of it being over 100 per cent as compared with the imperfectly purified standard copper of Matthiessen. The purest cathode copper—that is, an annealed sample of wire drawn directly from a cathode without melting—may run over 102 per cent; it is unusual, however, for copper that has been melted to run over 101 per cent. The lowering of conductivity by melting is due chiefly to the fact that much of the impurity content of the cathode is present merely as mechanical contamination,

*All book rights reserved by the author.

a certain proportion of which a melting will incorporate chemically. Then there is always the smaller opportunity for the copper to absorb impurities from outside sources during furnace refining.

In drawing copper into wire the coarse crystalline structure of cast copper is broken down into a fibrous structure much harder and stronger but of a lower electrical conductivity, due perhaps to a rearrangement of the system of series-parallel circuits made by copper crystals and matrix. The depression of conductivity bears a direct relation to the degree of hardness attained, as shown in Figs. 2, 3 and 4. (See Addicks, *Transactions*, American Institute of Electrical Engineers, vol. 22, p. 695.) It will be seen from Figs. 3 and 4 that the softening of a wire by annealing has a progressive character in the exact reverse direction from the hardening by working the metal.

In order to arrive at a definite standard for comparing conductivities, therefore, wire is annealed in order to obliterate the somewhat uncertain effect of hard drawing before a determination is made. On the other hand, either a partial annealing or an overheating or "burning" of the wire will give results below the truth.

FIG. 2. ANNEALED COPPER ROD OF DIFFERENT SIZES DRAWN TO NO. 12 B. & S.

It is therefore necessary to bring the wire to incipient red heat (about 900 deg. F., or 480 deg. C.) for a brief time in order to get consistent results. All errors, however, are on the safe side, as it is impossible to get unduly high conductivity figures by faulty manipulation.

Pitch or Set

The pitch, or set, of copper is an expression used to define the appearance of the free surface of a cast copper bar; that is, the bar may be of high, normal or low pitch or it may be "in set" or "out of set."

Molten copper readily dissolves the various gases with which it is brought in contact in the refining furnace, such as oxygen, carbon monoxide and dioxide, and sulphur dioxide. As the copper cools and sets in the mold excess gas is given off, and the proper control of this phenomenon is the secret of good furnace refining. As has been outlined in a previous article ("The Furnace Refining of Copper," Metallurgical & Chemical Engineering, vol. 17, p. 579), the bath after melting is allowed to oxidize and the resulting cuprous oxide dissolves and acts as a scorifying agent, the scoria is

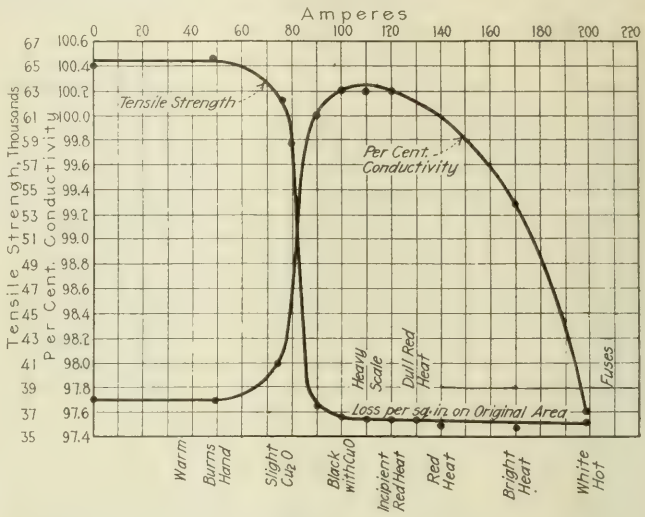

FIG. 3. ELECTRICAL ANNEALING OF NO. 12 B. & S. COPPER WIRE

skimmed off and the excess cuprous oxide reduced by poling. A button of copper cast in a "say-ladle" gives a characteristic set surface and fracture for each stage, the finished product showing a slightly swelling surface without deep wrinkles and a rose-red silken fracture. Should the poling not be carried far enough, the set surface will show a depression and the metal will be hard and somewhat sonorous. Metallographic examination will show thick veins of cuprous oxide eutectic, and careful inspection of the depressed set will reveal "niggerheads," or minute entrances to considerable cavities within. Fig. 5 shows a low set bar which has been planed to show a longitudinal cross-section, and one or two of these cavities are plainly shown. Such a bar may show red shortness in rolling or merely a slight hardness, but the cavities will roll out into small "cold sets" and are probably the main cause of splinters and slivers frequently met with in wire drawing. This phenomenon is identical with "piping" in steel and brass, which are always cast on end, the set surface being sheared off and rejected. Casting of copper on end has been advocated but never generally adopted except in the case of wedge cakes used for purposes where a special mirror polish is required in the rolled article and certain special shapes such as round billets.

If, on the other hand, poling is pushed too far, a reverse condition sets in. The surface bulges on setting and finally "spews over," throwing out worm-like excrescences; some excellent photographs of this condition are given by Hofman, Hayden and Hallowell, *Transactions*, American Institute of Mining Engineers, vol. 38, p. 175. This is analogous to the well-known "spitting" of silver. Such a bar shows perfect softness and malleability in rolling, but the worms have to be chipped off, and overpoled copper is not a satisfactory product. In general, however, the best pitch is one as high as consistent with the avoidance of overpoling.

Overpoled copper shows a slight depression in conductivity, as may be seen from the curve marked oxy-

gen in Fig. 1. The microscope shows the formation of some compound, presumably involving the gases of reduction or possibly sulphur. The latter element is present as included electrolyte in the cathode and in the products of furnace combustion, and until the sulphur has been worked out a charge of blister copper in an anode furnace will give a test button which will "throw a worm" quite similar to that of overpoled copper. Cases of mysterious aging and season cracking in brass have been traced to traces of sulphur, and it must be remembered that lake copper, which had at one time a special reputation in the manufacture of cartridge brass, did not enter the refining furnace with the possibility of faulty separation from a sulphate electrolyte in its past history.

An overpoled charge of copper exhibits instability of pitch, and the mere exposure to the air long enough to restore its depleted oxygen content is not sufficient

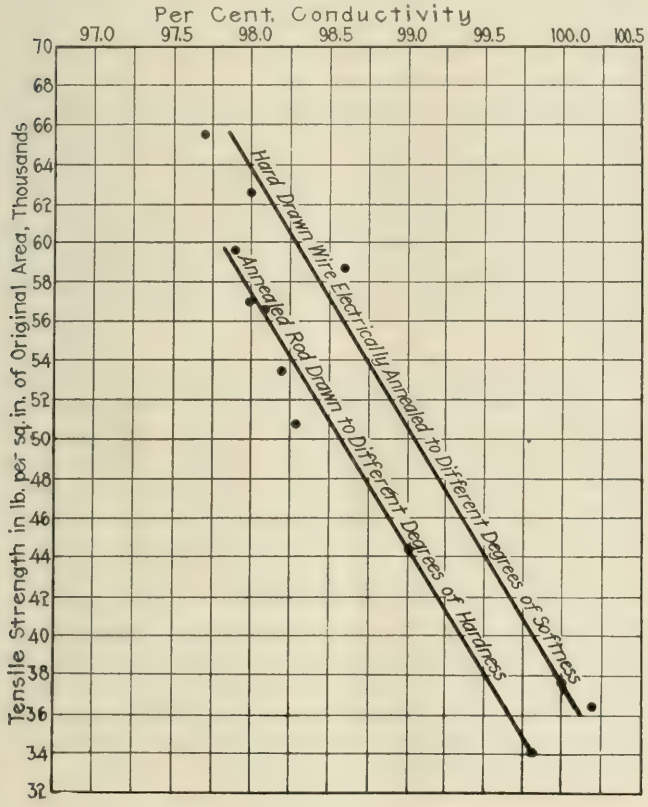

FIG. 4. RELATION BETWEEN CONDUCTIVITY AND TENSILE STRENGTH IN COPPER WIRE

to stabilize this wabbly pitch. It is, therefore, necessary to rescorify the entire charge, another indication that a new compound is formed in overpoling. Curiously enough, the addition of a minute proportion of metallic lead to an overpoled charge will stabilize it, but there is great danger of making the copper brittle. This corrective influence might also point to the presence of sulphur, inasmuch as while lead is insoluble in copper, leady copper matte is readily formed, and under special conditions lead and copper can be made to unite as they do in Allan's metal and in many Oriental bronzes.

The reason that foundries have such difficulty in making sound, high-conductivity castings of pure copper is that they get the copper badly below pitch in melting, so that they find it necessary to add various deoxidizing agents. Much phosphor bronze is nearly pure copper,

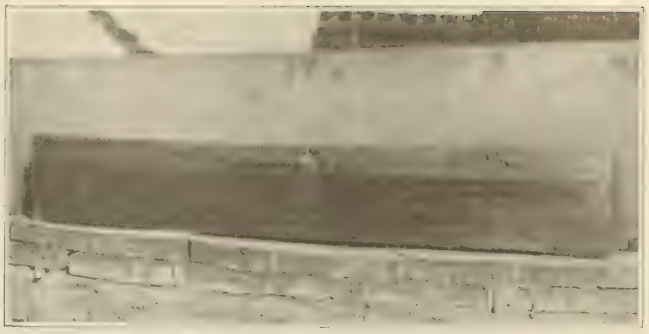

FIG. 5. GAS CAVITIES IN IMPROPERLY REFINED BARS

the phosphorus having vanished as volatile phosphorus pentoxide and merely served as a substitute for poling.

Copper which contains a considerable proportion of some other element—as in the case of arsenical lake running 0.5 per cent arsenic—will show a much coarser wrinkling of the set surface and to the practiced eye has quite a different appearance from pure copper. In the same way copper which has been poled with oil presents a peculiar appearance. Low set copper has heavy wrinkles and may cause cold sets in rolling.

Bars which break in the rolls are frequently found to possess a large cavity near the upper center as shown in Fig. 6, due to a lowness of set. A perfect set should be high and rounding like a mercury meniscus and not show a low level center and a high edge close to the sides where the mold chilled the copper. The wrinkles should be fine and the surface solid.

The set surface carries somewhat more dissolved oxide than the body of the bar. In Europe it was at one time the custom to plane this surface off before rolling when difficult specifications had to be met.

Ductility

While it is known that the addition of exceedingly small quantities of certain elements, such as lead, bismuth or tellurium, will make copper so red-short as to fall to pieces in rolling, it is quite impossible to state permissible limits of such elements on account of the neutralizing effects or various other impurities which may or may not be present. In general it is safe to say that nearly all troubles from brittleness may be traced to low pitch.

Well-refined high-grade copper can be hot rolled into quarter-inch rod which after pickling free of scale can be cold drawn into the finest wire without any intermediate annealing. In practice, however, there is always a certain percentage of "breaks" in the wire-drawing machines, and this percentage has been found to bear a direct relation to the copper contents of the lot of wirebars under test. It is, therefore, customary

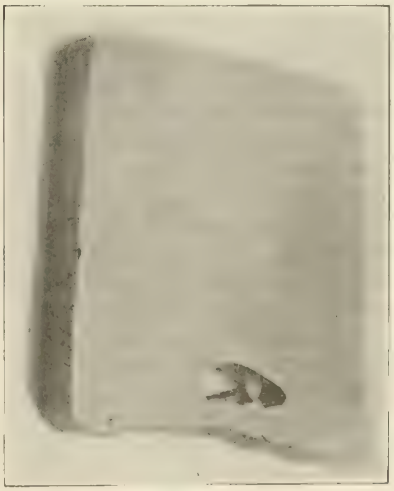

FIG. 6. GAS CAVITY IN LOW SET BAR

to impose, in addition to the conductivity specification, a requirement that the copper content (including silver) shall not be less than 99.88 per cent, a figure intended to represent a limit of 99.90 per cent after allowing a margin for assay precision.

The determination of traces of impurities in copper requires long experience. This is particularly true in the case of sulphur, where even the atmosphere of the laboratory must be free from sulphur compounds.

Mechanical tests on samples of wire as checks upon the character of the raw copper have been abandoned because the fabrication of the wire introduces so many variables. The former tests, as a rule, consisted of measurements of tensile strength and torsion.

Tensile Strength and Torsion

The tensile strength of copper wire depends upon the percentage of reduction in area after annealing, the speed and the temperature of drawing. With proper regard to these factors, almost any copper not too brittle to draw can be made to fulfill standard telephone wire specifications as to strength.

The usual torsion test was to determine the number of twists a No. 12 B. & S. (2.05 mm. diameter) hard-drawn wire would stand before snapping. This test is perfectly worthless, because it depends entirely upon the property of the thin skin which forms on wire in drawing. A wire as it comes from the drawbench when put in the testing machine will twist uniformly throughout its length for a few turns and then twist tightly at one point and snap. If the wire is scoured with emery paper or dipped for a moment in nitric acid before twisting, the skin is broken down and before snapping the entire length will coil tightly, giving several times the number of total twists formerly obtainable. This skin is at least in part due to imperfect pickling after rolling, as by the use of a nitric acid instead of sulphuric acid pickle on the rod the number of twists that the wire will stand is greatly increased. Particles of oxide scale are probably rolled into the metal, and sulphuric acid, while it will dissolve oxide, cannot cut metallic copper to reach it.

Sometimes bars are badly overheated in the heating furnace before rolling, and this probably causes absorption of gases and consequent brittleness. Altogether, mechanical tests have been entirely dropped as a check on the quality of the copper as distinguished from the finished wire.

Castings

In order to get a perfect casting from a physical point of view, the first requisite is that the copper should be in correct pitch, a subject which has already been discussed at some length. Small adjustments in pitch are made by adding or removing charcoal at the casting machine ladle. Next, the temperature of the copper must be high enough to insure good fluidity without burning the mold. The mold itself must be warm—that is, slightly above the boiling point of water—in order to avoid any condensation of moisture or too sudden chilling of the copper first striking it. There must be a fine film of a suitable mold wash to prevent sticking and the material used must be free of any volatile matter. The mold must be solid and free of pores which would entrap water; otherwise a spongy casting would result. The copper must flow in quickly but evenly and the casting machine must operate so smoothly that a partially set bar will be subject to no vibration or jars. The bars must be quenched in water soon after setting and this water must be warm. Finally, the molds must be free of warp and set truly level and filled to a given mark without any attempt at adjustment.

These many small points require very careful supervision at the casting wheel and carelessness in any one detail will give more or less defective product. Bars may be out of size, out of set, porous or contain splashes, fins, cold sets or "fish."

Out-of-size bars result from out-of-level or warped molds, or from careless filling to a wrong level. Too large a bar may result in the production of fins in the rolls, due to crowding. Molds suspended at the ends tend to drop in the middle and pinch at the top center.

Porosity may come from low set or may be due to moisture. It generally follows cold or porous molds or too high a casting temperature. In this connection it may be stated that copper molds turn out superior castings to iron ones, although the latter are more or less in use.

Splashes occur when the copper first strikes the mold, being thin sheets of metal which splash on the sides and freeze. Unless they are knocked off with a suitable tool before they are submerged, they are likely to leave a cold set or unwelded lamination in the bar.

Fins are sharp high edges due to filling the mold too rapidly or to vibration of the casting machine giving a wash to the bar before setting. They must be chiseled off the finished bar or they will be rolled in later.

Cold sets occur in various ways whenever molten copper is allowed to enfold cold splashes, etc. They must be chiseled out or, if extensive, the bar rejected.

Fish are bits of charcoal, nails or other foreign bodies allowed to become incorporated in the casting. They are supposed to be removed by a "fisher" during pouring much as a fly is rescued from a glass of milk.

The color of cast copper depends chiefly upon the time allowed to elapse between pouring and quenching and the temperature of the bosh water. The beautiful ruby shades are due to thin films of the lower oxides, and a slight change from the proper conditions will make bars either brassy or black. Twenty years ago good color was given great importance at the rolling mill, but it has nothing to do with the quality.

Dimensions

Each refinery issues a metal schedule giving the weights and dimensions of the market shapes it produces. This covers wirebars, cakes, ingots, ingotbars and billets. Very large wirebars, very heavy cakes and very large billets cast on end are poured by hand from a crane ladle and the additional cost over machine casting is reflected in a premium charged. Ingotbars are merely three ingots cast end to end in order to bring the weight up to a figure where steamships will accept them without demanding that they be barreled.

No rigid requirement as to regularity of size and weight is required of ingots and ingotbars which are to be remelted. In the case of wirebars, however, the American Society for Testing Materials specifications give a tolerance of 5 per cent in weight and ¼ in. in any dimension except that wirebars may vary 1 per cent in length and cakes 3 per cent in any dimension greater than 8 in.

For wirebars, each refinery has its own design and

proportions of point. Different rolling-mill men have such contradictory opinions regarding the relative advantages of slight changes in these matters that it is probable that one design is about as good as another. A long point enters the roll more easily at the first pass, but is apt to leave more scrap. A square cross-section is desirable, because a flat bar is apt to turn over in the rolls when part way through. The first pass is often a box roll and after that diamond and oval alternately.

American Wirebar Sizes

A refinery carries about six sets of standard molds and raises the weight of the bars cast from each set by suitably changing the depth to which the molds are filled within the limits imposed by the necessity of keeping a bar reasonably square in cross-section. An example from practice is shown in Table I.

Bars of 135 lb. and under are commonly used in Europe, but practically not at all in the United States, where the usual demand is between 175 and 225 lb. Very heavy bars, running around 800 lb., are in moderate demand on the Continent for making great lengths of trolley wire without reverting to the American practice of brazing.

Inasmuch as the great demand for power in a rolling mill is in the first two or three passes, the roller would prefer a long bar of small cross-section. This, however, would increase the difficulties in casting and in obtaining sound bars, and developments in this direction are improbable unless it be in connection with castings made on end.

TABLE I. TYPICAL AMERICAN WIREBAR SIZES

Weight, Lb.	Length, In.	Depth, In.	Top Width, In.	Bottom Width, In.
135	35¼	3⅞	3¾	3 5/16
175	47½	3⅝	3 11/16	3¼
200	49½	3⅞	4	3⅝
225	50	4 1/16	4	3⅝
250	56	3⅞	4⅛	3 5/16
275	55⅜	4 7/16	4½	4⅛
300	55½	4⅝	4½	4⅛

Cakes are the most troublesome class of castings to make. They have a large set surface and this is rolled out to a mirror-like finish where every flaw is readily seen. Often they are cast on "mixed" rings, so that wirebars are interspersed on the mold ring and, as perfect pitch for a wirebar is not necessarily perfect for a cake, a slight disadvantage results. It is quite impossible to cast a small ingot and a heavy cake from the same ladle without adjustment in pitch, as the shrinkage and gas release conditions are so different in the two cases.

Occasionally copper is shipped as cathodes in place of ingots. This is a perfectly logical procedure, as the furnace operation is not a true refining and it has been abundantly shown that a cathode really freed from electrolyte can be melted to high-grade copper without any furnace refining whatever. On the other hand, the cathodes must be sheared to a suitable size, they are often brittle and there is always more or less metal loss in transit. Aside from nodules being dropped by the wayside, pieces are easily broken off by thieves. Also cathodes are quite variable in individual quality, while in the refining furnace thousands are averaged together. The result is that ingots still hold their own in the brass trade, although a fair proportion of cathodes are sold on an allowance below the price of wirebar copper.

New York City.

Legal Notes

By Wellington Gustin

What May Be Done Under Contract to Purchase Requirements

The Supreme Court of Pennsylvania has handed down a decision in the case of the Diamond Alkali Co. against the Aetna Explosives Co. The alkali company had filed a bill in equity against the Aetna company for an accounting of profits realized on the resale of soda ash delivered to it by the complainant under a certain contract which constituted the basis of the action. (107 Atlantic, 711.)

The material part of the contract between the parties, and involved in the controversy, after stating mutual promises to sell and buy, was: "Quantity: Buyer's entire requirements during 1916; minimum quantity 180 tons per month and maximum 250 tons monthly."

The kind was to be 58 per cent light soda ash, shipped in carload lots, price $1 per 100 lb. Buyer was to give seller at least thirty days notice of his requirements for each ensuing month. The agreement closed with these words: "There are no understandings or agreements relative to this contract or its subject matter that are not fully expressed herein."

The case was disposed of in the court below on bill and answer. A decree was rendered ordering the accounting as desired, and the defendant appealed to the Supreme Court.

Findings of the Lower Court

In the lower court the Chancellor found six facts, but only the third and fifth ones were material in the case on appeal. These findings are:

"Third. The shipments of soda ash, pursuant to orders from defendant, were less than the minimum specified in the agreement."

"Fifth. Defendant purchased and plaintiff delivered soda ash, which defendant did not use in its business as a manufacturer of explosives, and the excess quantity so obtained was sold by the defendant at a profit."

Now, the decree in the lower court was based on this last, the Chancellor construing the contract to be such that defendant could order only such quantities of soda ash between the minimum and maximum limits as were required in the manufacture of explosives.

Finding of the Supreme Court

The Supreme Court said that although the concluding clause of the contract states there are no other agreements or understandings, the lower court read into this contract: "Buyer's entire requirements in its business as a manufacturer in 1916." By referring back to the statement as to the contract it will be seen the words used are: "Buyer's entire requirements during 1916." The court said the requirements of its business as a manufacturer during 1916 may not have been 180 tons of soda ash a month, but whether so or not, it was bound by the terms of its contract to take that quantity from the plaintiff. The minimum and maximum quantities fixed in the contract were not merely probable estimates of the quantities which the Aetna company was to take, but were the definite fixed quantities which it could demand and which the alkali company was bound to deliver. The latter was bound to hold itself in readiness to make shipments ordered under the con-

tract, and the former, in turn, was bound to receive the minimum contracted for. (256 Pa., 295.)

Under the lower court's construction of the contract the defendant Aetna company could not resell any portion of the minimum quantity which it was required to take, if it found that the entire quantity was not actually required in its business. The lower court was of the opinion that "if 250 tons monthly was the quantity required to meet defendant's needs, it could have called for delivery of that quantity, but if fifty tons were sufficient, it could not demand more."

The question of the bad faith of defendant was not involved in the controversy. The complainant had simply averred that defendant had ordered soda ash in excess of its requirements in its business of manufacturing explosives and had resold the same; that by so reselling the defendant had perverted the contract. But the Supreme Court said the mutual rights and obligations under the contract were alone involved, and these were that for one year the plaintiff must be prepared to deliver, and the defendant to take, not less than 180 tons of soda ash per month, with the right to demand seventy more each month. In fact, plaintiff furnished less than 180 tons each month, on defendant's orders.

Now, to find the defendant guilty of "perversion" of the contract, the Supreme Court said, words must be written into it in the face of the clearly expressed intention to the contrary of both parties as stated in the concluding clause.

Case of Highlands Chemical Co. vs. Matthews Cited

The court said the reading of words into a contract was attempted in Highlands Chemical Co. vs. Matthews, 76 N. Y., 145, where the contract provided that the plaintiff should supply defendant with oil of vitriol for one year, "total amount to be called for during that time to be not more than 10,000 or less than 7,000 carboys." The defendant called for the maximum quantity, which the plaintiff failed to deliver. In a suit to recover for what had been delivered, the defendant claimed as a set-off the difference between the market price and the contract price of what had not been delivered to him. Thereupon the plaintiff attempted to import into the contract words in effect that the acid was to be used in defendant's business, and that therefore he had no right to demand more than was required for that purpose. The Court of Appeals held this could not be done, saying: "The defendant was required to take the minimum amount, whether he needed or desired it for the purposes of his business or not; and the correlative obligation rested upon the plaintiff to deliver any amount within the maximum fixed by the contract, if called for by the defendant. The contract of the plaintiff is not to supply an amount within the limits named, if needed by the defendant in his business. To introduce this qualification would be adding a new term to the contract."

Decision of the Supreme Court

Relying on this, the Supreme Court said it was no concern of the plaintiff what defendant may have done with what it was obliged to receive. If the price of the product had fallen it would have been compelled to bear the loss, and the court held that plaintiff had no right to an accounting for profits or for what it did with any of the product delivered to it under the contract. Hence the decree was reversed and dismissed at cost of the plaintiff.

Damages Awarded Infant Employee

In a personal injury case the defendant company had employed the plaintiff to work upon a laundering machine in one of its plants in New Jersey. His specific work was to keep the edge of the goods which were run through the machine from curling or getting folded, as it passed over the rollers. His hand apparently became entangled in the machinery, was drawn in between two of the rollers and was crushed. The workman was under sixteen years of age at the time of the accident, which fact was not known to the company, as the plaintiff had himself represented to the company's superintendent that he was then over sixteen years old.

The plaintiff brought suit upon the common law liability of an employer to compensate an employee for injuries received in his employment by reason of the negligence of the master. Upon trial a verdict was returned for the plaintiff, and the company appealed. (Lesko vs. Liondale Bleach, Dye & Print Works, 107 Atlantic, 275.)

Employee's Misrepresentation as to Age Is No Defense

On its appeal to the New Jersey Supreme Court the company urged that the workmen's compensation act provided the only means by which an injured employee can recover compensation for injuries received in the course of and arising out of, his employment, and that it abrogates the common law liability of the master for such injuries. But the court said this provision of the statute limiting recovery to compensation applies only where the contract of hiring is a valid one, and not where the contract is prohibited by the statute law of the state, as in this case. But the company argued further that where the false representation as to age had been the inducing cause of the employment, the infant employee is estopped from taking advantage of the statute; or, stated in another way, will not be permitted to deny the truthfulness of his statement made as to his age whereby he secured employment.

However, the court held that the doctrine of estoppel had no application where the employment of the infant is in violation of the provisions of the factory act, although the master employing the infant believes the representation to be true.

Law's Aim Is to Protect Children

Another contention for a reversal of the judgment was that the employee assumed the ordinary risk in the normal operation of the machine which resulted in the injury. Now, the court pointed out, the primary purpose of the factory act is to protect all children who are too young to appreciate the dangers arising out of work, and said that when the legislature had distinctly established an age limit under which children shall not be employed, it, in effect, had declared that a child under that age limit does not have the mature judgment, experience and discretion necessary to engage safely in work prohibited by the statute; and, consequently, a boy employed in violation of the legislative mandate is not chargeable with contributory negligence, or with having assumed the risks arising out of that employment.

Lastly, it was urged the verdict was excessive, but the court held the evidence did not justify a reduction. The verdict of the lower court was sustained.

Theoretical Study of Nitrogen Fixation by the Electric Arc—IV

Kinetic Aspects of the Nitrogen-Oxygen Reactions—Effect of the Arc in Dissociating N_2, O_2 and NO—Influence of Molecular Vibration Speeds—Probability Law—Concentrations of NO—Principles of the Electric Arc*

By CHARLES P. STEINMETZ

WHILE it is frequently assumed that the production of NO by the arc is merely a thermal effect, due to the high temperature of the arc, already Haber, Koenig and others have expressed the opinion that the nitrifying action of the arc discharge is at least partly a direct electrical effect, and have brought forward experimental evidence showing that under certain conditions arcs may give NO concentration far above those which could be expected by the thermal action. Further evidence for a direct chemical effect in the arc is given by Hayden in the A. I. E. E. *Transactions*, and a report of Dr. Noyes refers to the same possibility of a direct electronic action in nitrification.

My experience with electrical arcs has led me to the opinion that the nitrifying effect of the arc discharge is primarily a direct electrical effect, a dissociation of the gases in the arc stream into free atoms and a recombination of the free atoms into all possible combinations by the probability law, and that the thermal effect is a secondary one, in limiting the amount of NO which can be recovered from the arc.

The electric arc discharge probably is the most powerful dissociating agent, as seen by most chemical compounds in the arc giving the elementary spectra.

The phenomenon of nitrification by the arc then would be as follows:

In the arc stream, that is, the gas column which carries the electric current, the molecules of N_2 and O_2 are dissociated into their free atoms N and O. When leaving the arc stream, or when the arc stream stops by interruption of the current and the electrification action thus is withdrawn, these free atoms recombine, N with N, O with O and N with O, thus giving a mixture of N_2, O_2 and NO in the proportions determined by the probability law of the atoms meeting each other. If the temperature of the arc stream is so low that the dissociation velocity of NO is negligible, as might probably be the case with the mercury arc or with cadmium and zinc arc, this gas mixture survives; if the temperature of the gases coming from the arc stream is so high that the dissociation velocity is considerable, dissociation of NO occurs, the more the slower the temperature drops.

However, the formation of NO by the probability law from the dissociated gases in the arc stream and the dissociation by the temperature law during the cooling of the gases coming from the hot arc would merely be a theoretical segregation of the two phases of the phenomenon. In reality, when the electrical action of the arc is withdrawn from the mass of hot dissociated gases, N atoms meeting with N atoms will usually combine to N_2 molecules, unless their velocity, that is, temperature, is above the dissociation temperature of N_2. So O atoms meeting with other O atoms will usually combine to O_2 molecules; but N atoms meeting with O atoms will usually not combine, unless their velocity happens to be low, that is, materially below the average corresponding to the temperature, until the average velocity, that is, the temperature, has fallen sufficiently, for instance by giving off velocity to slow moving molecules, that is, by mixture with cold gases. If then the average velocity, that is, the temperature, falls slowly, before it has fallen sufficiently to permit the formation of many NO molecules, most of the free atoms of N and O will have vanished by combining to N_2 and O_2 molecules. The quicker thus the cooling of the hot mixture of dissociated gases the more N and O atoms would survive to the temperature where NO can form to any great extent.

The phenomenon thus would be that of the approach to equilibrium conditions of a mixture of N, O, N_2, O_2 and NO, from a mixture of N and O produced by the arc. If the arc temperature is very high, and the reaction velocity thus extremely high, it can easily be seen that the condition of thermal equilibrium, by Nernst's equation, preponderates, unless extremely rapid cooling is possible. Only with arcs of relatively low temperature, or extremely rapid cooling (such as is possible with very thin, that is, low current, arcs, which are rapidly and frequently interrupted, as for instance by the Bradley-Lovejoy method of arc nitrification), a material difference in the result may be expected, if the phenomenon is not thermal but electrical. It is under these conditions that abnormally high concentrations, etc., have been observed by Koenig and others.

However, since the Bradley-Lovejoy process was a commercial failure, and the Birkland-Eyde process in Norway a success, at least under the conditions prevailing there, most of the attention of the investigators has since been concentrated on the latter process. In this, however, due to the large high-current high-temperature arc, the thermal phenomenon probably predominates.

Nevertheless, in my opinion, the evidence is strongly in favor of the assumption that the effect in the arc is primarily an electrical one, a dissociation of the molecules into free atoms, and then recombination of these by the probability law, limited by the temperature stability of the resulting products.

Assuming then that a gas mixture like air, consisting of:

n_0 g. mol. N_2

o_0 g. mol. O_2

b g. mol. neutral gases, as A, etc.,

*For Parts I, II and III see CHEM. & MET. ENG., vol. 22, Nos. 7, 8 and 9, Feb. 18 and 25 and March 3, 1920, pp. 299, 353 and 411.

where:

$$n_o + o_o + b = 1$$

is dissociated by the arc, and the free atoms, recombining by the probability law, then from the gas mixture of:

n g. mol. N_2
o g. mol. O_2
a g. mol. NO
b g. mol. neutral gases.

where:

$$n + o + a + b = 1$$

The probability, in the dissociated state, of an N atom meeting another N atom, that is, of two N atoms meeting each other, bears to the probability of an N atom meeting an O atom, the ratio:

$$n : a = \frac{n_o}{2} : o_o \qquad (101)$$

The probability of an O atom meeting another O atom bears to that of an O atom meeting an N atom the ratio:

$$o : a = \frac{o_o}{2} : n_o \qquad (102)$$

(101) and (102) give:

$$n : a : o = n_o^2 : 2n_o o_o : o_o^2 \qquad (103)$$

and since

$$n + a + o = n_o + o_o = 1 - b \qquad (104)$$

It is:

$$a = \frac{2n_o o_o}{1-b}$$

$$n = \frac{n_o^2}{1-b}$$

$$o = \frac{o_o^2}{1-b} \qquad (105)$$

which gives:

	Air		1 : 1 Mixture of N_2 and O_2	
	Before Passing the Arc	After Passing the Arc	Before Passing the Arc	After Passing the Arc
N_2 concentration.....	$n_o = 0.777$	$n = 0.6116$	$n_o = 0.50$	$n = 0.25$
O_2 concentration.....	$o_o = 0.210$	$o = 0.0447$	$o_o = 0.50$	$o = 0.25$
NO concentration.....	.....	$a = 0.3307$	.....	$a = 0.50$
Neutrals, concentration b	$= 0.013$	$b = 0.013$	.....	.....

According hereto, the air coming from the arc stream would have an equilibrium concentration of NO of about 33 per cent, if the thermal equilibrium concentrations are left entirely out of consideration, as could be done only if the arc temperature is very low. Otherwise the NO concentration will be reduced by dissociation due to the approach to the thermal equilibrium at a rate depending on the initial temperature and the rapidity of the cooling. It probably makes no material, if any, difference if we assume the electrical equilibrium established instantly and the concentration resulting therefrom then reduced by the condition of thermal equilibrium, or if we assume both effects occurring simultaneously, as probably the case, and thus these high concentrations never reached. We may thus use the first assumption, that is, segregating the thermal and the electrical effect, as it allows us to calculate from the initial concentration of the chemical equilibrium, by the laws of thermal equilibrium, the residual NO concentration from the rate of cooling.

Dissociation Acceleration Constant

The velocity of thermal dissociation is, by (12):

$$v = -\frac{da}{dt} = c_2 a^2 - c_1 \left(n - \frac{a}{2}\right)\left(o - \frac{a}{2}\right) \qquad (106)$$

At concentration a, much above the thermal equilibrium concentration, as would be the case here, the second term of equation (106) is negligible, as seen from the table of reaction velocities III. Thus it is:

$$v = \frac{da}{dt} = c_2 a^2 \qquad (107)$$

It is then:

$$\frac{dv}{dT} = a^2 \frac{dc_2}{dT} + 2ac_2 \frac{da}{dT}$$

As a is independent of the temperature T, that is, a change of T does not change a except through c_2, it is:

$$\frac{da}{dT} = 0$$

Thus:

$$\frac{dv}{dT} = a^2 \frac{dc_2}{dT} \qquad (108)$$

It is, however, by (23)

$$\log_{10} c = -10.887 + 5.731T \times 10^{-3} \qquad (109)$$

or:

$$\log_e c_2 = -25.07 + 13.20T \times 10^{-3} \qquad (110)$$

Herefrom follows:

$$\frac{dc_2}{dT} = 13.20 \times 10^{-3} c_2 \qquad (111)$$

Substituting (111) into (108) gives:

$$\frac{dv}{dT} = 13.20 \times 10^{-3} a^2 c_2 \qquad (112)$$

Substituting (107) into (112) gives:

$$\frac{dv}{dT} = 13.20 \times 10^{-3} v \qquad (113)$$

Thus, integrated:

$$\log_e \frac{v}{v_o} = 13.20 \times 10^{-3} (T - T_o) \qquad (114)$$

where

v_o and T_o are two corresponding values, or, in common logarithms:

$$\log_{10} \frac{v}{v_o} = 5.731 \times 10^{-3} (T - T_o) \qquad (115)$$

That is, for constant temperature intervals $(T - T_o)$, the dissociation-velocity increases by a constant factor.

For $(T - T_o) = 100$, or 100 deg. rise of temperature, $\frac{v}{v_o} = 3.74$ fold, or the action velocity increases 3.74 times; for 200 deg. temperature rise, 14.0 fold.

From (114) follows

$$v = v_o e^{s(T - T_o)} \qquad (116)$$

where:

$$s = 13.2 \times 10^{-3} = .0132 \qquad (117)$$

Thus:

$$\frac{da}{dt} = -v_o e^{s(T - T_o)} \qquad (118)$$

If now the cooling of the gas mixture is carried out by the cooling function:

$$\frac{dT}{dt} = -f(T, t) = -bT^n \qquad (119)$$

That is, the gases are cooled proportional to some power of the temperature ($n = 4$: radiation; $n = 1$: conduction, approximately; $n = 0$: constant rate of cooling) it is:

$$\frac{da}{dT} = \frac{da}{dt} : \frac{dT}{dt} = \frac{v_o e^{s(T - T_o)}}{f(T, t)} = \frac{v_o e^{s(T - T_o)}}{bT^n} \qquad (120)$$

Thus, integrated:

$$a_1 - a = \frac{v_o}{b} e^{-sT_o} \int_T^{T_1} T^n e^{sT} dT \qquad (121)$$

for $n = 0$, or constant rate of cooling, this gives:

$$a_1 - a = \frac{v_o e^{-sT_o}}{sb}\left[e^{sT_1} - e^{sT}\right] \qquad (122)$$

If T_1 is the high initial gas temperature, T the much lower final temperature, the second term is negligible compared with the first term, and equation (122) simplifies to:

$$a_1 - a = \frac{V_o}{sb} e^{s(T_1 - T_o)} \qquad (123)$$

where a_1 and T_1 are the initial concentration and initial temperature, v_o the dissociation velocity at temperature T_o.

Substituting (107)

$$a_1 - a = \frac{c_2 {a_o}^2}{s\,b} e^{s(T_1 - T_o)} \qquad (124)$$

or, making $T_o = T_1$, thus $a_o = a_1$:

$$\frac{a_1 - a}{{a_1}^2} = \frac{c_2}{sb} \qquad (125)$$

and by (110):

$$c_2 = e^{-25.07 + sT_1} \qquad (126)$$

Thus:

$$a_1 - a = \frac{{a_1}^2}{sb} e^{sT_1 - 25.07} \qquad (127)$$

$$\log_{10}(a_1 - a) = 2\log_{10} a_1 - \log_{10} s \log_{10} b + .4343\, sT_1 - 10.887$$
$$= 5.731 \times 10^{-3} T_1 - 10.887 + 2\log_{10} a_1 - b - 8.121$$
$$= 5.731 \times 10^{-3} T_1 - \log_{10} b + 2\log_{10} a_1 - 9.008 \qquad (128)$$

If:

$a_1 = .33$

It is:

$\log_{10}(a_1 - a) + 5.731 \times 10^{-3} T_1 - \log_{10} b - 9.971$

or, if a and a_1 are given in per cent:

$\log_{10}(33 - a) = 5.731 \times 10^{-3} T_1 - \log_{10} b - 7.971$ (129)

or, approximately:

$\log_{10}(33 - a) = 5.731 \times 10^{-3} T_1 - \log_{10} b - 8$ (130)

That is, with an arc temperature or initial temperature T_1 and cooling constant b, starting with the initial concentration of electrical equilibrium of 33 per cent NO, the final concentration a, after cooling at constant rate, to temperatures where the dissociation velocity has become negligible, is given by equation (130).

However, this equation involves the assumption that a is high compared with the equilibrium concentration, and ceases to apply if a approaches the thermal equilibrium concentration. It may be used, however, to determine the range of T and b, within which an appreciable part of the initial concentration $a_1 = 33$ per cent can be saved; outside of this range, the thermal equilibrium conditions prevail.

From (129) follows:

$$T_1 = \frac{\log_{10}(33 - a) + \log_{10} b + 7.971}{5.731} \times 10^3 \qquad (131)$$

Residual Concentrations

In Table XIII (see p. 416) are given, for a cooling rate of $b = 10^5$ per sec., the arc temperature T_1, which gives various residual NO concentrations a, from 0, that is, temperature equilibrium, up to 32.9 per cent. These values are plotted in dotted lines, with the temperature as abscissæ, in Fig. 11.

Table XIV gives the arc temperatures required at various cooling rates b, from 1 to 10^8 deg. per sec., to give various residual concentrations, from $a = 32$ per cent, that is, practically chemical equilibrium, and the thermal effect does not yet come into consideration, up to $a = 0$, that is, the residual concentration is entirely determined by the temperature equilibrium.

These values are plotted in Fig. 13, with the cooling rate b as abscissæ and the temperature as ordinates. As seen, at each cooling rate, there is (theoretically) a relatively narrow temperature range of less than 300 deg., in which the effect changes from electrical to thermal. With arc temperatures above this critical range, the effect is entirely thermal; with arc temperatures below this range, it is entirely electrical, while with arcs of a temperature within this range, it is partly thermal, partly electrical. Thus at a cooling rate of $b = 10^5$, at arc temperatures above 2530 deg. abs. the NO concentration entirely depends on the thermal equilibrium; but at an arc temperature of 2460 deg. abs., or only 70 deg. lower, already a concentration of 20 per cent NO, if produced electrically, could survive, while at arc temperatures below 2260 deg. abs., practically the entire electrical equilibrium concentration of NO would survive.

Table XV then gives for an average cooling rate $b = 10^5$, that is, a rate varying for the different parts of the air between 10^3 and 10^7, the concentration which would result at various arc temperatures, when cooling the gases to 1400 deg. abs., by mixing air at 400 deg. abs., with the arc stream, A, with an electrical equilibrium of 33 per cent NO in the arc stream, B, with the action being entirely thermal.

In Figs. 11 and 12 are plotted the values of the residual concentration of the arc gases, and the concentration of the gas mixture resulting from the arc and the cool air, with the arc temperature as abscissæ. Fig. 12 gives the values in a larger scale, for electrical and thermal equilibrium, while Fig. 11 shows only the electrical equilibrium conditions, but shows the critical temperature range, where the action changes

TABLE XV. EQUILIBRIUM

Average cooling rate: $b = 10^5$ deg. per sec. distributed as follows:

from thermal at higher, to electrical at lower temperatures.

It must be realized, however, that this matter of very high concentration in the arc stream, resulting from the probability law, is entirely speculative, and while there is good evidence for the assumption that the nitrifying action of the arc stream is not a mere thermal effect, but that a direct electrical effect comes in, it is not probable that the action is as simple as assumed in the preceding, nor that such high concentrations are reached, and more experimental evidence is necessary before fully understanding the nitrifying action of the electric arc. It is more probable that the concentrations

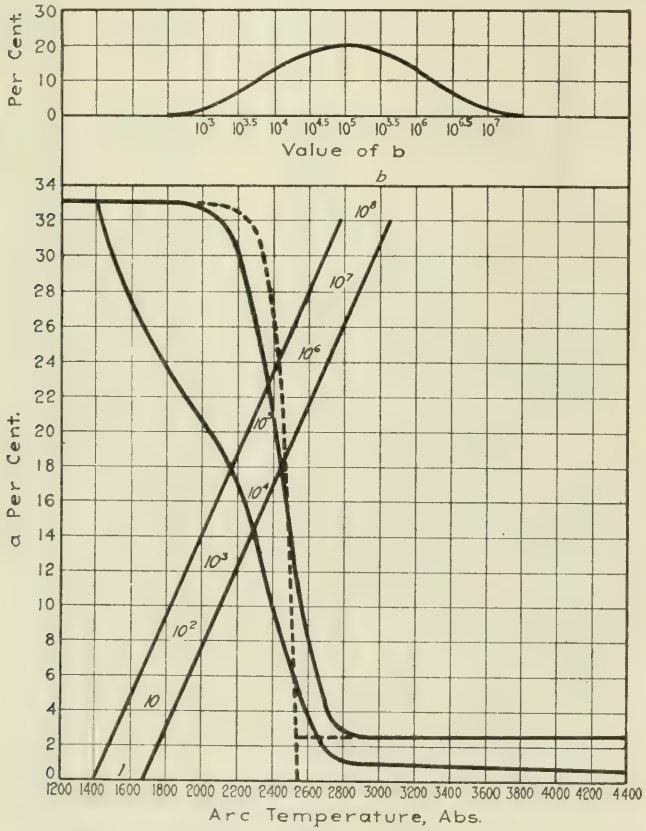

FIG. 11. ELECTRO-THERMAL EQUILIBRIUM *NO* CONCENTRATION

brought about by direct electrical action are much higher than those of thermal equilibrium, especially at lower arc temperatures, but are still far below the values given by the probability law, as assumed above.

Appendix: The Arc

As seen, the problem of economical, that is, efficient, nitrogen fixation by the electric arc is essentially dependent on the physical and electrochemical characteristics of the electric arc, in the solution of designing the operating conditions such as to produce the maximum amount of electrochemical action with the minimum expenditure of energy in the arc. Unfortunately, our knowledge of the physical and electrochemical characteristics of the various forms and types of electric arcs is still so limited that an intelligent and systematic design of arc nitrification processes for maximum efficiency will not be possible unless very much more is known on the nature of stationary and transient arcs, and before much further advance can be made a systematic research into the electric arc and its properties thus appears essential.

In the following shall therefore be given a short outline of our knowledge of the physical and other characteristics of electric arcs, as far as known, to serve as a starting point for further research on arcs.

The Normal Arc

In the following we shall limit ourselves to the presentation and discussion of the physical characteristics of the arc, without considering their theoretical explanations by the ionic theory or otherwise.

The typical or normal arc is best illustrated by the passage of a unidirectional continuous current between two terminals, of metal or similar conductors, such as carbon, magnetite, titanium carbide, etc., in an atmosphere of constant pressure, while not disturbed by air currents, external magnetic or electrostatic fields, etc.

The melting point of carbon is above its boiling point at atmospheric pressure. Therefore, when using carbon as arc terminals, no fused spot or pool can form on the terminal, as with other materials in which the

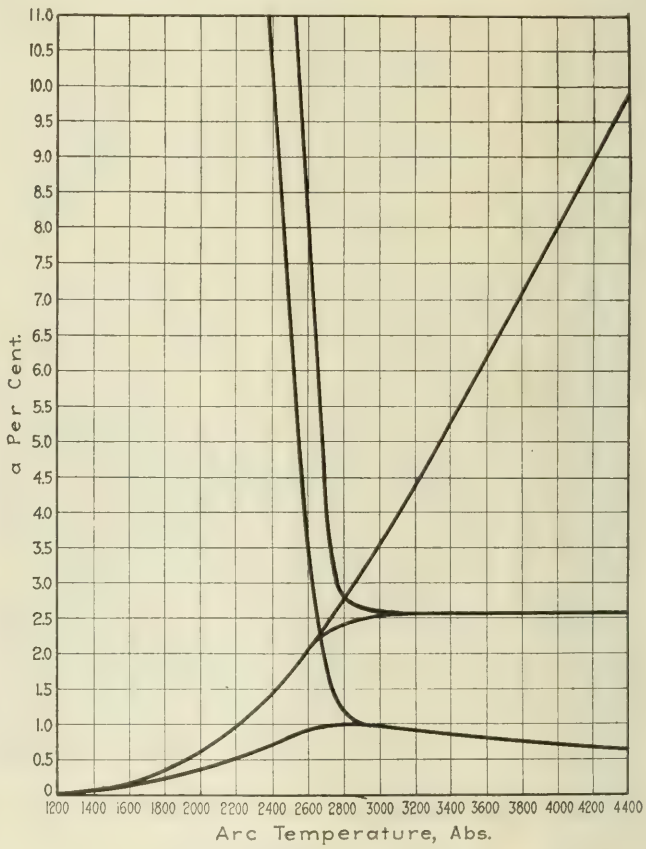

FIG. 12. ELECTRO-THERMAL AND THERMAL EQUILIBRIUM *NO* CONCENTRATION

melting point is below the boiling point. Also, at the temperature of the boiling point of carbon, the dielectric strength of gases and vapors has decreased so much that they are practically conductors. Therefore, the unidirectional character of arc condition is little pronounced in the carbon arc, and with alternating current supply the momentary interruption of the current at its reversal does not interfere with the arc. In these two characteristics, and the features depending upon them, the carbon arc differs from other typical arcs, so that the carbon arc is not well suited for the study of the characteristics of the typical arc. Well suited for this purpose are the mercury arc and the iron or magnetic arc, as the spectra of these two metals are very

sensitive to the temperature, the relative intensity of their lines greatly changing with the temperature and thereby affording a means of judging of the temperature.

Arc Spectrum

The light of the normal arc always shows the spectrum of the cathode material throughout the entire arc length, even if the cathode is strongly cooled. It seems herefrom that the presence of cathode material in the arc stream is necessary for the arc conduction.[1]

The spectrum of the anode material generally does not appear in the arc stream. Only if the anode contains material which is much more volatile than the cathode material, and the anode is allowed to become hot, the spectrum of such material appears in the arc stream. But even then it often appears only in that part of the arc stream next to the anode, and does not extend to the cathode, or at least occasionally fades out from the part of the arc stream near the cathode, sometimes with a sharp boundary line where the anode spectrum ends.

The intensity of the spectrum of the anode material in the arc stream is reduced by cooling the anode, or making it so large as not to get very hot, and the anodic spectrum may entirely disappear by cooling, at least from the part of the arc stream nearer the cathode.

It seems herefrom that the presence of anode material in the arc stream is not essential for the arc conduction, but that such material enters the arc stream rather by heat evaporation.

The cathode is gradually consumed by feeding material into the arc stream, and though this consumption of cathode material can be greatly reduced by cooling the cathode (relatively), it can apparently never entirely be eliminated. The consumption of the anode, however, greatly varies with its temperature, and by keeping the anode cool, as by making it larger, the consumption of the anode can not only be entirely suppressed, but the anode made to increase in weight, by the deposition of cathode material on it.

Continuity of Arc

The arc conduction is continuous, that is, the current must flow continuously, and when once interrupted for even a very short time, the arc ceases and does not start again when the voltage is reapplied, but to restart it by reapplying voltage such voltage must be so high as to jump a static spark across the arc terminals through the gas or vapor existing between them. Thus in general, alternating current arcs cannot be operated at the voltage sufficient to maintain a direct current arc between the same terminals, but go out at the end of the half wave of current. Only when the temperature of the arc stream is so high—as in the carbon arc—that the voltage required to jump the spark across the residual vapor between the electrodes is of the same low magnitude as the voltage required to maintain the arc, alternating arcs can be operated without materially higher voltage than direct current arcs.

The arc can be shifted from one anode to another one, not in contact with the former, by bringing the second anode into the arc stream. If then the second anode is nearer to the cathode than the former, or is given a higher potential difference against the cathode, the arc leaves the former anode and goes to the latter, either gradually or suddenly, or it may even be made to divide between the two anodes. The arc, therefore, does not need to be continuous at the anode.

A rod of insulating material or even a rod of metal may be passed through the arc stream without disturbing it. Thus the arc does not need to be continuous in the stream.

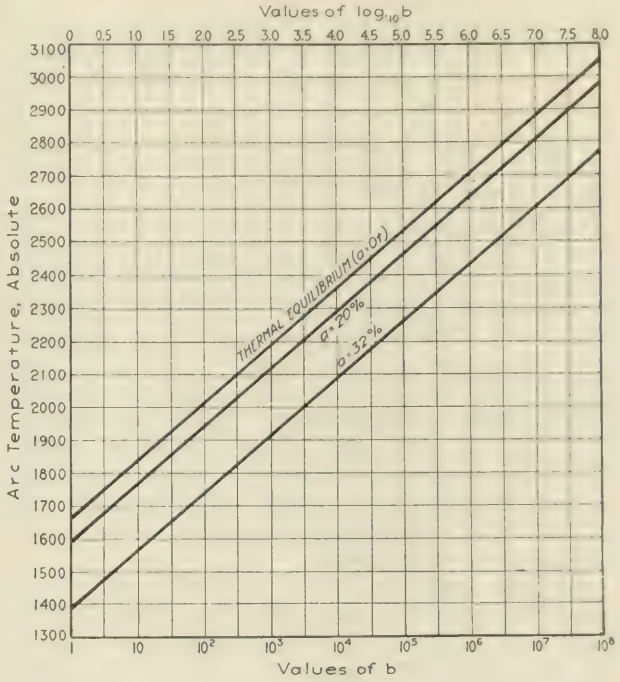

FIG. 13. ELECTRO-THERMAL EQUILIBRIUM

The arc cannot be shifted from one cathode to another one not in contact with the former, by immersing the latter into the arc stream, even if the second cathode is materially nearer to the anode, or of materially higher negative potential difference against the anode, unless the voltage between the second cathode and the anode is so high as to jump a spark and thereby start a new arc; as the spark voltage greatly decreases with the temperature, by immersing a second small cathode into the arc stream, after some time, the arc may jump to it, when the jump spark voltage has decreased by the second cathode becoming sufficiently hot. The arc can shift from one cathode to another one only when the second cathode is in direct contact with the first, and the negative terminal of the arc stream, or the "negative spot," moves continuously from one to the other cathode.

Cathode Stream

All these phenomena combined afford a strong evidence that the vapor of the negative terminal is an essential factor in the conduction of the current by the arc between the terminals, or, as it may be expressed, that the "cathode vapor stream," or "negative vapor stream," is the arc conductor which carries the current across the gap between the terminals. This statement, however, involves no assumption on the way the current is conducted, or on the nature of the conduction. The conduction might, for instance, be explained as ionic conduction in which the cathode vapor stream

[1] An apparent exception herefrom may occur when the cathode consists of a very refractory material, such as carbon, and the surrounding atmosphere consists of a gas or vapor which is a good arc conductor. Thus a typical mercury arc may be operated between two carbon electrodes in an evacuated space filled with mercury vapor. But even then the cathode disintegrates, and it is rather probable that the arc starts as carbon arcs, but transfers to the mercury vapor. The cathode in this case has the characteristics of the cathode of a carbon arc, and not that of a mercury arc.

plays a similar part as the metal conductor in the passage of the current through a copper wire, except that in the arc conductor, the cathode vapor stream is produced by the current, varies with it, and depends on it, and thus ceases with an interruption of the current.

Arc Temperature

Usually in the normal arc, by cooling the arc stream near the cathode, the major part of the cathode vapor can be condensed, or by cooling the cathode, the amount of cathode vapor which is produced can be greatly reduced, without appreciably affecting the electrical characteristics of the arc and the nature of its spectrum. Herefrom seems to follow that the amount of vapor produced at the cathode and existing in the arc stream is in the normal arc usually very much greater than the amount required to carry the current.

At constant pressure of the atmosphere surrounding the arc, the spectrum of the cathode vapor stream does not change with the change of current or voltage of the arc, but is the same with long arcs or short arcs, with arcs of small current or large current, though the amount of cathode vapor in the latter is much larger. The spectrum does not change either, if much of the cathode vapor is condensed out of the arc stream by cooling it near the cathode, or cooling the cathode. This is the case even with such arc conductors as mercury or iron vapor, in which the spectrum greatly changes with the temperature; and the spectrum is the low temperature spectrum.

Herefrom seems to follow that the temperature of the arc stream in the normal arc is constant and that at constant pressure of the surrounding atmosphere it depends only on the material of the cathode, and that it is the temperature of the boiling point of the cathode material. With an increase of the gas pressure of the surrounding atmosphere, the spectrum of the cathode stream of the normal arc changes in such manner as it would be changed by an increase of temperature. Thus with the mercury arc, the red lines, which are extremely faint in the mercury arc spectrum at high vacuum, become more prominent.

Mercury and Iron Arc

The mercury arc offers the most convenient way of studying these relations, as its temperature is relatively low, and in its commercial forms it is operated over a wide range of pressure, from high vacuum to more than atmospheric pressure. In the vacuum mercury arc in a glass tube, with sufficiently large condensing chamber beyond the anode, the current can be varied over a considerable range, and the outside temperature may vary between high summer and low winter temperature, but the spectrum remains the same, showing the red lines very faintly, while a carbon filament, inserted longitudinally into the arc stream, remains entirely dark (when seen through a red glass to cut off the mercury light), though entirely immersed into the arc stream, thus showing that the temperature of the arc stream is below incandescence. If, however, the condensing chamber is covered by a heat insulator, obstructing the escape of heat, and thus the condensation, the vapor pressure rises, and the red lines of the mercury spectrum become noticeable and even quite prominent, while a carbon filament immersed in the arc stream becomes incandescent,[2] both showing an increase of temperature of the arc stream. At the same time, the voltage consumed by the arc stream increases. With a mercury arc in a quartz tube, at atmospheric pressure, the red lines of the spectrum are still more prominent, showing still higher temperature, and the voltage per unit length of the arc stream is higher.

If in a vacuum mercury arc in a glass tube the condensing chamber is placed beyond the anode, so that all the mercury vapor must pass through the arc stream, exposure to low winter temperature does not affect the spectrum, though much of the vapor is condensed out of the stream, showing that a small part of the vapor is sufficient for conduction. So, also, an air blast, unless very powerful, has no effect. If, however, the condensing chamber is located near the cathode, so that the surplus mercury vapor produced at the cathode does not pass through the arc stream, but is condensed before reaching the stream, then exposure to winter temperature, or even a moderate cooling blast against the arc tube, changes the spectrum. The red spectrum lines become more prominent, and the exploring carbon filament in the center of the arc stream becomes incandescent, thus showing an increase of temperature of the arc stream, though the vapor pressure has decreased. In this case, it seems, the condensation has gone so far that not sufficient mercury vapor is left in the arc stream to carry the current, and the mercury vapor apparently becomes superheated. This would then not be a normal arc any more, but an arc in superheated vapor, or a "gas arc."

By passing a high-frequency condenser discharge through a mercury vapor tube, we get an arc in which the red mercury lines are much more prominent than the green lines, and the color of the light is pinkish red. In this case, the currents are very high, but of so short duration that they cannot produce much mercury vapor, and the residual mercury vapor in the tube, in carrying the large momentary currents, is very highly superheated.

The iron arc also can be used to study these relations, though not so conveniently, due to its higher temperature. In the iron spectrum, the change with the temperature is the reverse from that of the mercury spectrum. In the iron spectrum, the intensity maximum shifts toward shorter wave lengths, with increasing temperature. Thus, while the radiation of the direct current iron arc at atmospheric pressure, with a temperature probably the boiling point of iron, gives essentially white light, a condenser discharge between cold iron terminals gives very little visible light, but a large amount of ultra-violet radiation, and is indeed the most convenient source of ultra-violet light.

Transient or Gas Arc

Herefrom the conclusion seems to be justified that the temperature of the arc stream in the normal arc is the temperature of the boiling point of the material in the arc stream, that is, is the boiling point of the cathode material and therefore constant for all normal arcs of the same cathode material, at constant pressure of the surrounding atmosphere, but increases with increasing, and decreases with decreasing pressure of the atmosphere surrounding the arc. A rise of temperature of the arc stream above the boiling point of the cathode material would occur only by the sudden application of large current of such short duration that there is no time to form a sufficiently large saturated

[2]This does not mean that the arc stream is above incandescence, as the filament, longitudinal to the arc, shunts some current from the arc in this case, and thereby becomes heated.

vapor stream, or by such intense cooling of the arc stream that by condensation the amount of material in the cathode stream is reduced below the amount of saturated vapor required to carry the current.

In very long (relatively) arcs of short duration the former may be the case, especially if the arc terminals are cooled and thereby the amount of vapor reduced, and if the arcs are rapidly moved by air currents, magnetic fields, etc. In such arcs the voltage is increased beyond that required to carry the current across the gap between the electrodes in a normal arc through a bridge of saturated cathode vapor. Such arcs may in the middle of the arc stream show hardly a trace of the spectrum of the cathode material, but give essentially the spectrum of the surrounding atmosphere.

Such arcs may be called "gas arcs," as the conduction is by the gas existing in the space surrounding the arc, or "air arcs." They are not normal arcs, cannot persist for any length of time in stationary condition, but then would change to normal arcs by a cathode vapor bridge forming. Thus they must either be continuously moved through the air, by air currents, magnetic or electrostatic fields, mechanical motion of their terminals, etc., or must be of short duration, started and again interrupted.

Such gas arcs give the spectrum of the surrounding atmosphere, but show little, if any, of the spectrum of the electrode material, and that only near the electrodes. Their temperature probably depends very little on the electrode material, but very largely on the gas pressure of the surrounding atmosphere, and probably also on the nature of this atmosphere. It is doubtful whether a well defined arc stream ever forms, due to the transient nature of such arcs.

Very little is known of the electrical and other characteristics of such arcs, and experimental investigation is greatly needed, as it is these gas arcs or "transient arcs" which are the means of nitrogen fixation in the arc process.

Equations of the Arc

No entirely satisfactory equation has yet been derived expressing the relations between the constants of the arc, such as voltage, current, arc length, gas pressure in space surrounding the arc, etc. For the normal or stationary arc at constant gas pressure, several more or less approximate forms of equation have been proposed, but for the transient or gas arcs, which are the ones of importance in nitrification, practically no data are available, as far as I know.

The voltage consumed by a stationary or normal arc consists of two parts: a voltage consumed at the arc terminal, the terminal drop, and a voltage consumed along the arc stream, the stream voltage.

The terminal drop is independent of the current in the arc, and apparently also of the gas pressure in the space surrounding the arc, but is a function of the material of the arc terminal, and in general the lower the more volatile the material of the arc terminal. It varies from 13 volts with mercury to about 16 volts with cadmium and zinc, to 30 volts with iron and its conducting compounds, to about 36 volts with carbon. Apparently, at least with some materials such as carbon, not all the terminal drop is at the terminal surface itself, but a part of it in the vapor space immediately surrounding the terminal.

The stream voltage is approximately proportional to the arc length, it depends on the material of the arc stream, and is in general the lower the more volatile the material of the terminal and thus of the arc stream. It increases with increasing, and decreases with decreasing gas pressure in the space surrounding the arc. It increases with decrease of current, and decreases with increase of current and as first approximation frequently has been assumed as inversely proportional to the current, and the stream voltage e_1 expressed by the equation:

$$e_1 = \frac{cl}{i} \qquad (1)$$

where l is the arc length, and c a constant.

The total arc voltage then would be:

$$e = e_0 + \frac{cl}{i} \qquad (2)$$

where e_0 is the terminal drop.

This equation (2) is not infrequently found in theoretical discussions of arcs. It is, however, not even approximately correct, and while the stream voltage varies with the current, and in opposite direction to it, its variation is much less than inverse proportional to the current.

From a large amount of experimental data with arcs of various lengths and currents, with various different electrode materials, I once derived the empirical equation giving the arc stream voltage as inverse proportional to the square root of the current, that is,[3]

$$e_1 = \frac{cl}{\sqrt{i}} \qquad (3)$$

and:

$$e = e_0 + \frac{cl}{\sqrt{i}} \qquad (4)$$

or rather:

$$e = e_0 + \frac{c(l + \delta)}{\sqrt{i}} \qquad (5)$$

where δ is a small correction term in the arc length l, which apparently corrects for the heat and other energy losses from the end of the arc toward the electrode.

Still more extended investigations on arcs, recently undertaken, and covering a much wider range of arc length, current, etc., seem to show that equation (5) is not rigidly correct. It is, however, a far closer approximation than any other proposed arc equation in my knowledge, so that, pending further investigation, equation (5) may be considered as representative of the normal or stationary arc.

This equation (5) has the further advantage that it is not merely empirical—though derived empirically—but appears rational.

Assuming the amount of electrode vapor carried into and through the arc stream as proportional to the current, which appears reasonable, at constant gas pressure in the space surrounding the arc, the arc section then is proportional to the current. This seems to agree with experimental evidence. Consider now that the electric power consumed in the arc stream, $e_1\ i$, must be dissipated from its surface, by conduction, convection and radiation. If then, as seems probable from the previous consideration, the arc temperature —with given electrode material and constant gas pressure in the surrounding space—is constant, then the energy dissipation per unit surface of arc stream is constant, that is, $e_1\ i$ is proportional to the arc length l and proportional to its circumference, that is, the

[3] *American Institute of Electrical Engineers, Transactions*, 1906, p. 789; "Transformation of Electric Power Into Light."

square root of its section and thus of the current, that is:

$$e_1 \, i = c \, l \, \sqrt{i}$$

and herefrom immediately follows equation (3):

$$e_1 = \frac{cl}{\sqrt{i}}$$

Also, if the mass of arc vapor is proportional to the current, at constant temperature, the power required to produce the arc stream vapor is proportional to the current, $= c' \, i$.

Considering, as reasonable, the terminal drop e_o of the arc as the electrical equivalent of the power required to produce the arc vapor, it is:

$$e_o i = c' \, i$$

This gives:

$e_o =$ const., that is, the terminal drop is constant, independent of current and arc length, but dependent upon the arc temperature and thus the electrode material.

The following are approximate values, for a few materials, of the constants e_o, c, δ in the arc equation (5) for a normal arc at atmospheric pressure with the arc length l given in cm.:

	e_o Volts	c	δ cm.
Mercury	13	..	....
Zinc and cadmium	16	..	....
Iron and magnetite	30	50	0.12
Titanium and its carbide	31	..	....
Carbon	36	52	0.8

Determining the Active Strength of Sulphate Cooking Liquor

Recent experiments have determined that the action of NaOH is substantially twice as drastic as that of Na_2S between the ratios of one part NaOH to one part of Na_2S and four parts NaOH to one part Na_2S when applied to sulphate cooking liquor.

The active strength of the cooking solution in terms of NaOH is expressed by the equation $S = M + (N \div 2)$, where S is the active strength of the solution, M the concentration of NaOH, and N the concentration of Na_2S.

A rapid method of determining the strength of a cooking solution is as follows: Add 10 c.c. of cooking liquor to about 50 c.c. of water in a porcelain dish. Add 10 c.c. of a saturated solution of $BaCl_2$. Stir vigorously, and titrate with normal hydrochloric acid to phenolphthalein end point. The number of c.c. required is directly proportional to the strength. This method is the most convenient for use in the digester house, because of its simplicity and the fact that it does not involve a consideration of the ratio of NaOH to Na_2S.—*Abstract from Forest Products Laboratory "Technical Notes."*

British Research Associations

Under the provisions laid down by the British Government for the organization of research associations in different industries and trades, thirteen associations have been formed, four are in an advanced state of development, three are under consideration and three more are proposed. Among the industries which have taken advantage of the government's co-operation in scientific and industrial research are sugar, iron, photography, portland cement, scientific instruments, rubber, glass, refractory materials, non-ferrous metals and shale oil.

Investigation of Fatigue of Metals

An investigation of fatigue phenomena in metals under repeated stress has just been started under the joint auspices of the National Research Council, Engineering Foundation, and the Engineering Experiment Station of the University of Illinois. The Engineering Foundation is providing $15,000 a year for two years for this investigation and the Engineering Division of the National Research Council is acting in an advisory capacity, largely through its Committee on Fatigue Phenomena in Metals. The experimental work is being done in the laboratories of the Engineering Experiment Station of the University of Illinois, under the immediate direction of Prof. H. F. Moore, research professor of engineering materials and chairman of the committee above mentioned.

Plans are laid for a two years' program of tests, and apparatus and material are already arriving for the tests. It is hoped to secure a considerable amount of data on tests of various metals, including a number of tests of each metal to 100,000,000 reversals of stress. It is hoped to study the various short-time physical tests which are used for metals—such as the impact test, magnetic analysis, and short-time bending tests—to see whether any of these tests give reliable indices of the ability of the metal to resist fatigue under millions of repetitions of low stress. It is hoped that some reliable commercial test for this important property may be developed by this investigation.

A test party of four or five persons is being organized and the University of Illinois is fitting up a special laboratory with about 2500 sq.ft. of floor space for the use of this investigation.

Borax in Fertilizers

Two pounds per acre of anhydrous borax marks the limit of safety with which it may be used in fertilizer when the fertilizer is put in the row so that seeds or plants are brought into virtual contact with it. This is the opinion of the specialists of the Department of Agriculture who have been studying the matter of borax in fertilizer. As a result the Department has advised all fertilizer manufacturers and dealers in fertilizer that more than 2 lb. of borax per ton of mixed fertilizers will not be allowed unless the presence of an excess of that amount is indicated plainly on the container.

When fertilizer is broadcasted and thoroughly mixed with the soil, the Department's specialists agree, 10 lb. of borax may be contained in the fertilizer used on an acre of ground without danger to the crops. The Department describes the experience of farmers in some sections of the country as disastrous as a result of using fertilizers containing borax. It is to guard against a similar experience that the Department on Dec. 9 put into effect its drastic regulations regarding the borax content of fertilizer.

Borax is described as being "highly toxic to crop plants," and was contained in the potash derived from at least one of the new sources which were resorted to after the war had cut off foreign supplies of potash. The Department also has ascertained that nitrate of soda as imported also contained some borax. The Department is also authority for the statement that borax was "not known to have been present in appreciable quantities in the materials commercially available for fertilizer uses prior to the war."

The Technology Plan

By William H. Walker
Director of the Division of Industrial Co-operation and Research, Mass. Inst. of Technology

THE Technology Plan is an organized attempt to effect a closer co-operation between scientific and industrial effort; between the technical school and the individual industry throughout the country. Although a working relationship between educational institutions and industrial organizations has been discussed at great length, and on many occasions, little real practical progress has as yet been made.

The Technology Plan recognizes that for the present, at least, there must exist somewhere in this scheme of co-operation an element of individual and mutual responsibility on the part of those engaged in it. It recognizes that a purely philanthropic enterprise does not engender in the managers of industry that confidence which is an essential element in its success. Such men are not yet deeply interested in a strictly *pro bono publico* method of co-operative work. Hence the Technology Plan is neither eleemosynary in organization nor philanthropic in its aims and methods.

Essential Feature of the Plan

The essential feature of the plan is an agreement, expressed as a contract, between individual industrial organizations and the Massachusetts Institute of Technology, under which the industry pays an annual retaining fee to the Institute, in return for which the Institute assumes certain definite obligations of such a character as it is in position to meet. These obligations are in very general terms as follows:

The great demand of the industries today is for men trained to solve the many problems with which these industries are confronted. This requires, first, a knowledge of the principles of science, and second, a training in the application of this knowledge to the solution of the ever-recurring difficulties. While the first requirement is reasonably well met by the undergraduate courses of instruction at the Institute, only to a limited extent can the second be obtained in the four years allotted to undergraduate work. The student must be encouraged to spend an additional year or more in a research laboratory or advanced study.

Students Taught to Solve Industrial Problems

Since the best way to learn an art is to practice it, the student is best taught to solve industrial problems by having him attempt the solution of such problems under able and experienced guidance. These problems, however, have their origin in, and owe their existence to, the industries themselves. The first point of co-operative contact, therefore, in this arrangement between industry and the Institute of Technology is that the Institute agrees to use, so far as it can, such problems as the industry will submit to it as basic material for its research work for those graduate students interested in industrial development; to give men already well grounded in science the benefit of the opportunity of working under experienced instructors upon the type of work for which they are urgently required.

Steady Stream of Trained Men for Industry

It is true also that much investigation in "pure science" can be conducted as profitably in fields of research which are closely akin to industry as in those realms of science far remote from general interest. This does not mean that the search for knowledge for its own sake will not continue to subtend a large arc of the activities of the Institute of Technology; but rather that such search will be activated and inspired by the realization that the hard work involved and the results obtained are recognized as an essential part of a comprehensive whole. Hence the Institute agrees in its contract to maintain a steady stream of trained men constantly flowing into industry with the best preparation for scientific work which it is possible for it to give. Also, the results of research work thus obtained will swell the store of knowledge on which the scientific progress of the community as a whole depends.

To Seek Appropriate Positions for the Graduates

But a corollary of this duty of preparing educated men is the duty to see that, as far as possible, these men take positions for which their natural ability and aptitude most nearly fit them. Further, it is desirable that, as these men develop into specialists in any particular field, their sphere of usefulness be made as wide as is practicable. Hence the Institute undertakes to maintain a record of the qualifications, experience and special knowledge of its alumni; to advise the contractor where such knowledge and experience as it seeks is available; to assist the contractor to obtain the technical help he requires, whether from its own alumni or from available engineers elsewhere. While this service has been rendered to some degree in the past, it has been a minor part of, and incidental to, other activities. It will now become a contractual obligation.

Executives Also to Be Educated

Coincident with the education of scientific men, there exists the necessity of educating the executives of the industries in the great economic value of science when applied to the business of their organizations. The sporadic "Yankee genius" of the past, productive though it was, must be replaced by the method of scientific research. Genius must be provided with that most efficient tool yet produced—scientific method. While it is true that the world will ever need more knowledge, the pressing duty of industry for the present is to apply the knowledge now available. To meet this situation, the Institute provides for conferences with members of its staff, not only in its own building but also at the factories of the contractor. It is hoped that the contractor will be so imbued with the possible benefits to be derived by the application of science that he will avail himself of one of the sources of technical aid readily accessible, not only at the Institute, but among consulting engineers and industrial scientists throughout the country.

Close Co-operation Sought

A realization of that close co-operation between the industrial interests and the educational institutions of the country which in Germany was made so effective by the domination of both by the state can, in America, be brought about only by a voluntary personal relationship between the executives of the companies and the instructing staffs of the institutions. The Technology Plan aims to make this relationship more easily possible; to provide a point of contact between the two interests; to open a channel of communication through which the manufacturer and the technical consultant can more easily meet. The contractor can obtain the value of his retainer only by utilizing the facilities thus made

available. There will therefore be present in the Technology Plan this incentive, at least to try.

The instructing staff of an educational institution is made up, at least theoretically, of men peculiarly adapted to render great public service by conducting research of a fundamental character, i.e., they are seekers after new knowledge, and yet, at the same time, are teachers and trainers of young men. It is important that these men be not withdrawn into purely industrial work by reason of the greater financial return offered by great corporations, or the acute pleasure which many red-blooded men feel in being professionally connected with great technical developments. Hence the Technology Plan provides a method by which the staff is enabled to profit by contact with men of affairs and receive the inspiration which comes from the capitalization of effort, and, at the same time, fertilize and catalyze the instructional work of the teaching staff.

Hope Is to Interest Consulting Engineers Throughout the Country

The Institute, therefore, agrees that if the contractor has special technical problems requiring extended consultations, investigations, tests or research work it will advise the contractor where and by whom such service can best be rendered. When one considers the splendid laboratories with which the Institute of Technology is equipped, covering as they do almost every department of applied science, and its staff, trained in the use of such laboratories, it is obvious that much of the work will be done within its own organization. But it is neither the desire nor the intention of the Technology Plan to limit the contractor to the facilities of the Institute. It is the hope of the Division of Industrial Co-operation and Research, the organization set up to handle the 190 contracts already made, that it can enlist the interest of the great body of able consulting engineers throughout the country. When, therefore, consultation, test, investigations or research work are of such nature as can be best furnished by established commercial organizations, the Institute will advise the contractor where, in its judgment, the work can best be cared for.

The Technology Plan is, therefore, a more effective means of introducing technical research to the manufacturer; of making the application of science to industrial problems popular; of creating an appreciation on the part of the leaders of industry of the value of science and the necessity of providing, not alone for its application, but for its continued growth and development.

Copy of the Contract

Following is a copy of the contract between companies and Massachusetts Institute of Technology:

Agreement made this (blank) day of (blank) 19.... between (blank), hereinafter referred to as the Company, and the Massachusetts Institute of Technology.

The Company agrees to pay to the Massachusetts Institute of Technology a retainer of (blank) dollars, in five annual installments of (blank), payable on the second day of January of each year from 1920 to 1924 inclusive.

The Massachusetts Institute of Technology agrees to make available to the Company, during the five years 1920 to 1924 inclusive, its library and files, and to arrange for conferences with its technical staff on problems pertaining to the business of the Company.

The Massachusetts Institute of Technology further agrees to maintain a record of the qualifications, experience and special knowledge of its alumni that shall be as complete as practicable, and upon request to advise and assist the Company to obtain:

Information as to where such knowledge and experience are available.

Information regarding men for special problems.

Information regarding men for permanent employment.

The Massachusetts Institute of Technology further agrees to maintain a list of undergraduates who may wish positions upon graduation: to advise the Company upon request as to the records and qualifications of these men, and to arrange for interviews with them.

The Massachusetts Institute of Technology further agrees that in case the Company at any time during the period covered by this contract should have special technical problems requiring extended consultations, investigations, tests, or research work, it will advise the Company where this service can be best obtained. If, in the judgment of the Massachusetts Institute of Technology, this service can best be rendered by its staff or in its laboratories, a member of its staff shall undertake such service for a fee to be mutually agreed upon by the parties hereto.

It is earnestly hoped that the plan here outlined will be adopted with improvements by other educational institutions for the benefit of both education and industry.

Cambridge, Mass.

Chemical Industry in Sweden

The Roberts Co. is making essences in Oerebro. A match factory has two plants for the production of phosphorus by the electric smelting method, which will satisfy the Swedish match industry, according to the *Zeitschrift für Angewandte Chemie.* Potassium nitrate is made by the double decomposition method. A government commission is looking into the manufacture of common salt from sea water. A soda works, making sodium carbonate by the Leblanc method, was undertaken during the war, and it was still uncertain in September last whether it would continue or not. There are a number of works established for the production of chromium salts, but only one of them remains and its future is dependent upon protection, according to the report published in the *Journal* of the Society of Chemical Industry. An aluminum works is under construction to reduce the metal from refractory loam by an unpublished process. Calcium carbide and calcium cyanamide are produced on a large scale, and ammonium sulphate has been made from the cyanamide in limited quantities. The country expects to be independent in future in regard to caustic soda, caustic potash and bleaching powder. Making sodium hypochlorite has been discontinued. The Birkeland-Eyde establishment at Ljunga has a small ammonia oxidation plant, and it is only here that atmospheric nitrates are made and sold. In the chlorate establishment at Trollhättan some other material than platinum is used for electrodes.

The Bohemian Glass Industry

The well-known glass-manufacturing district of Jablonec (Gablonz), in the Republic of Czechoslovakia, alone exported from Feb. 1 to Oct. 31, 1919, products valued at 17,000,000 Czechoslovak crowns, mostly to the United States, France and Italy. Previous to the war, of the 202 glass furnaces in the Austro-Hungarian empire, 162 were in the Czechoslovak domain. Of the total production for 1913, valued at 117,400,000 crowns (the normal value of the Austro-Hungarian crown was 20c. United States currency), 105,500,000 crowns represented the Czech and Slovak products.

SOUTHERN COTTON OIL CO.'S SAVANNAH WORKS

Pictorial Description of the Cotton Oil Industry

Comparative Statistics of Food Values and Efficiency of Refining Practice of Cottonseed Oil — Photographs in Sequence Illustrating the Industry From the Boll on Through the Gin, Oil Press, Refinery, Packaging and Shipping Departments

By DAVID WESSON

As a summary to the presidential address[1] before the American Institute of Chemical Engineers, the accompanying collection of photographs, charts and tables were projected on the screen, with the intention of giving the audience a better mental picture of the cotton oil industry than could be conveyed by means of words alone.

The relative value of different foods is indicated in Fig. 1. In the first column, the percentage of fat in different food materials is shown and in the last column, the number of calories per lb. It will be noticed that the vegetable oils show 4,080 calories and are the most concentrated foods on the list.

The relative digestibility of different fats is charted in Fig. 2. This has been worked up from data furnished by the Bureau of Home Economics, based on the careful experimental work of Dr. Holmes. The upper part of the list shows the principal animal fats, the lower part gives the various vegetable fats and oils. The coefficient of digestibility is shown in figures in the first column and graphically in the second. It will be noticed that, with one exception, all the fats shown have coefficients above 90, while the vegetable oils all run between 95 and 100. It is quite evident from this table that the claim frequently made that olive oil is more digestible than cottonseed oil is not substantiated. We must bear in mind, in looking at the next three figures, that we are dealing with statistics. You must remember that Mark Twain used to say, "There are three kinds of lies, namely, lies, damned lies, and statistics"; we can say, however, on governmental authority—and we all believe what our Government tells us—that the statistics I am showing herewith are at least 90 per cent correct.

Fig. 3 shows the relative production of vegetable oils in the United States as compared with the production of animal fats. Leading the list of the vegetable oils is cottonseed oil, while at the bottom of the list is olive oil, which is hardly visible in the chart. The dotted lines after linseed, cocoanut, peanut and soya bean oils indicate the additional amount of these oils which was imported into the country in 1918. Please pay particular attention to the difference in the production of lard compounds, or *vegetable shortenings*, as they should be called, and lard. It will be noticed that they amount to more than the hog product. Please notice also the great difference between the production of butter fat and oleomargarine. With the present high cost of living, there is no question that the latter should be produced in much greater quantities.

The growth of the cotton oil industry is shown in Fig. 4. It will be noted that in 1870 only about 4 per cent of the crop was crushed, while in 1917-18 about 90 per cent of the crop was crushed. The other curves show the millions of tons of seed and the millions of barrels of oil.

Table I shows the statistics for the cotton oil industry for the year ended July 31, 1919.

TABLE I. SEED AND PRODUCTS YEAR ENDED JULY 31, 1919

Seed crushed, 4,450,189 tons at $70.00	$311,513,230
Oil made, 1,319,926,000 lb. at $0.17½	230,900,000
Cake and meal, 2,158,787 tons at $50.00	107,939,350
Hulls, 1,124,118 tons at $15.00	16,861,770
Lint, 929,199 bales (500 lb.) at $0.04½	21,696,797
Total value mill products	$377,397,917

Plate 1 gives a good view of a cotton field during the picking season. This view was taken some years ago when labor was far more plentiful than at present.

Fig. 5 shows the relation between the market prices of seed and summer yellow oil during the war period.

Plate 2 is an enlarged illustration of a single cotton boll.

When the cotton is picked, it is hauled to the gin. Plate 3 gives a good idea of a gin during the picking season. Loads of seed cotton are lined up awaiting their turn. It looks like a rather uneconomical system to have a whole lot of teams and men standing idle losing a number of hours' good time waiting for the cotton to go through the gin. This picture, however, was

[1] History and Development of the Cottonseed Oil Industry. CHEM. & MET. ENG., vol. 21, No. 13, pp. 661-662.

taken some years ago, when labor was not so scarce as it is now.

A good idea of the interior of a gin house is given in Plate 4, showing the gins to the right and the baling press to the left. Ventilating pipes carry off the dust and dirt from the cotton as it is being ginned. The gins consist of a lot of rapidly revolving saws which tear off the fiber from the seed. The fiber and seed are delivered separately, the fiber going into the baling press, and the seed being delivered to the mills. Plate 5 shows how seed looks in a small pile. It represents about a handful of seed.

Fig. 6 shows two sections of the cottonseed. The little black dots seen throughout the seed contain a resinous coloring matter called "gossypol," which is responsible for the dark color in the crude oil. The seeds are really small nuts about $\frac{3}{8}$ in. long and about $\frac{3}{16}$ in. in diameter. They are surrounded by a leathery shell or hull, from which grow the cotton fibers. The gin

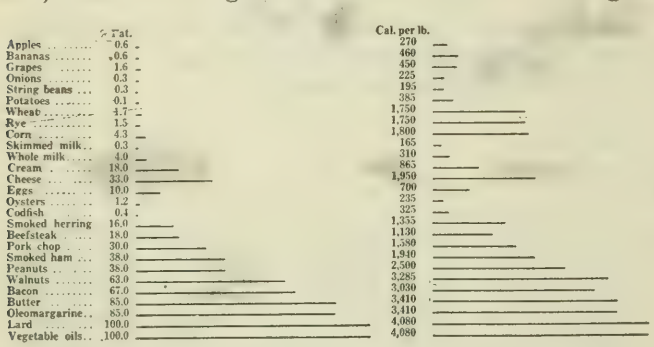

FIG. 1. RELATIVE VALUE OF DIFFERENT FOODS

always leaves a certain amount of fiber adhering to the hull. Fig. 7 shows an enlarged section of the cottonseed, portraying particularly the structure of the hull, as well as the kernel.

Table II shows analyses of cottonseed from Georgia and Texas. Please notice the big variation in the percentage of oil in the meats, that in Georgia being very much higher than that in the Texas seed, while the ammonia and protein are much higher in the Texas than in the Georgia seed.

When the seed reach the mill, they are first unloaded from the cars or wagons and delivered to the seed house. This seed house, Plate 6, is for a small mill. Ordinarily,

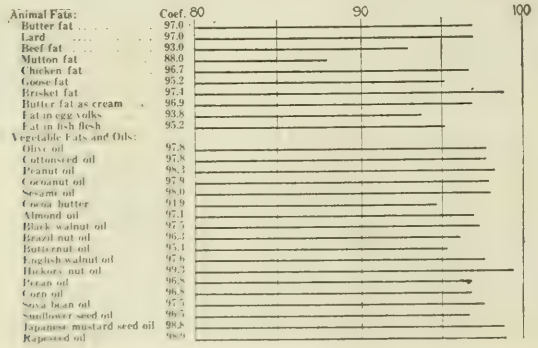

FIG. 2. RELATIVE DIGESTIBILITY OF FATS

at the bottom of the tunnel is a conveyor, into which the seed is shovelled. In a small mill, however, a conveyor is not necessary, as the seed can be put into carts and carried from the tunnel when the house is full. It is then emptied into the elevator boot at the end of the building, as shown in Plate 7.

A shaking screen which separates the seed from the bolls, stones, sticks, etc., is shown in Plate 8. The trash is collected in a bag at one end of the screen, while the clean seed is fed to a conveyor, which carries the seed to the linters, shown in the background of Plate 9. These linters are really gins which remove the lint re-

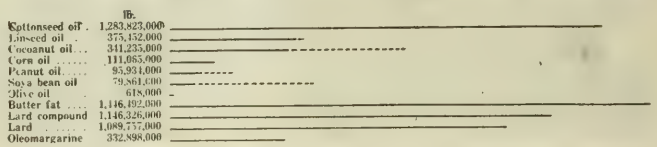

FIG. 3. PRODUCTION IN U. S. OF VEGETABLE OILS COMPARED WITH ANIMAL FATS

maining on the seed. The quality of the lint depends on the amount removed per ton of seed. During the war, the Government demanded the largest possible output, and it was the practice to remove 150 lb. of lint per ton of seed. This lint contained considerable cut hull and trash. Good practice at the present time removes 80 to 100 lb., while, if a superior quality is desired, two cuts are made: the first cut taking off 25 to 40 lb., while the second cut yields the inferior lint, as much being removed as may be desired. The linted seed next passes through the hullers, which chop the seed up fine. The mixture of hulls and meats is then passed through a series of screens and reels, which separate the hulls from the meats. Plate 10 gives a good idea of the appearance of the separating machinery in a modern mill.

Plate 11 shows a picture of a model press room, which looks as though it had been cleaned up for shutting down the mill for an indefinite period. It is altogether too clean for a mill in actual operation!

Plate 12 was taken while the mill was working. In the center is shown a French heater, where the meats are cooked, while, to the left of it, is shown the cake

TABLE II. COTTONSEED ANALYSES

	Georgia, Per Cent	Texas, Per Cent
Hulls	45.00	47.00
Meats	55.00	53.00
Oil in meats	37.00	31.20
NH_3 in meats	6.60	8.40
Protein in meats	36.99	43.50
Mill yields per ton of seed:	Pound	Pound
Cake	1,010.00*	1,056.00*
Oil	337.50	256.00
Linters	155.00	145.00
Hulls	375.00	515.00
Loss	123.00	100.00
* NH_3 in cake, per cent	7.16	8.00

former, where the cooked meats are formed up into cakes before going to the presses. The broom in the foreground is a guarantee that this picture was not fixed up for the photographer.

Another view in the same press room is given in Plate 13, showing the working of the presses. These presses make two or three turns an hour. In figuring the capacity of the mill, it is common practice to figure one ton of seed for each press plate for 24 hr.

Plate 14 shows the meal shed, where the cake, after being taken from the presses and ground, is piled up in bags ready for shipment. Plate 15 is a typical illustration of an old-time oil mill. At one end is the mill proper with the boiler and engine room, next to which is the press room, and, beyond the linters, a separating machine, while at the further end is shown the seed house, on one side, and the hull and meal houses on the other. Plate 16 is a modern mill. The large building to the right is the seed house, and the low building to

the left is the mill proper. This mill is operated mostly by electricity.

The latest thing in oil mill construction is illustrated in Plate 17. It is the New South Oil Mill at Helena, Ark. The concrete cylindrical tanks are used for storing the seed, and, according to reports, there has been no trouble so far this season from the seed heating or otherwise deteriorating.

With the reservations made regarding statistics, Fig. 8, compiled partly from the results given by D. A. Tompkins in his work on "Cotton and Cottonseed Oil," published about 1901, shows the improvement made in cottonseed milling from 1875 to 1920. In the early days of the industry, the seed was considered to be half hulls and half meats. Not much attention was paid to waste, and, besides, the gins left a great deal more fiber on the hulls than they do at present. In 1875, it will be noticed, the yield from a ton of seed was 225 lb. of oil and 675 lb. of meal. At that time, the hulls were

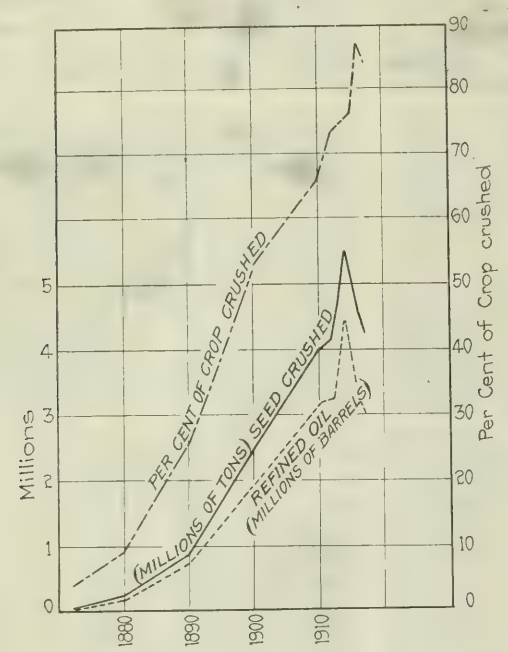

FIG. 4. GROWTH OF THE COTTON OIL INDUSTRY

burned under the boilers and not much attention paid to them. The large proportion of oil left in the meal will be noticed. In 1900 a much larger output of oil is shown, while account is made of the lint and loss, amount of hulls being the same. In 1920 we would have a quite different yield, only 60 lb. of oil being left behind in the meal, which, it will be noticed, amounts to 980 lb. altogether. It will also be noticed there is a large yield of lint, while the hulls are shrunk to 490 lb. The rest of them are something like the salesman's overcoat and the expense account; in this case, the missing hulls have disappeared in the meal.

Fig. 9 shows the results of milling a ton of seed for the year ended July 31, 1919. The crude oil, as it comes from the mill, is very dark in color, averaging about that of claret, but with a somewhat brownish cast. When it reaches the refinery, it is pumped into refining tanks shown in Plate 18, holding from 60,000 to 120,000 lb. These are provided with agitating machinery, and also large steam coils for heating the oil rapidly. Above the tanks are smaller ones for weighing or measuring in the caustic soda required for the refining. The proper amount of caustic is run into the oil, while it is being agitated, and, after the agitation has continued for some little time, small flakes begin to form. The machinery is then slowed down and heat applied. The flakes grow larger and larger, and owing to the decreased density of the oil, on account of the heating, the flakes soon begin to flow, and when in the right condition for settling rapidly, the steam and agitation are shut off, and the tanks are allowed to settle, preferably for 24 hr. Plate 19 represents the bottom of the refining kettle, provided with a cone and heating

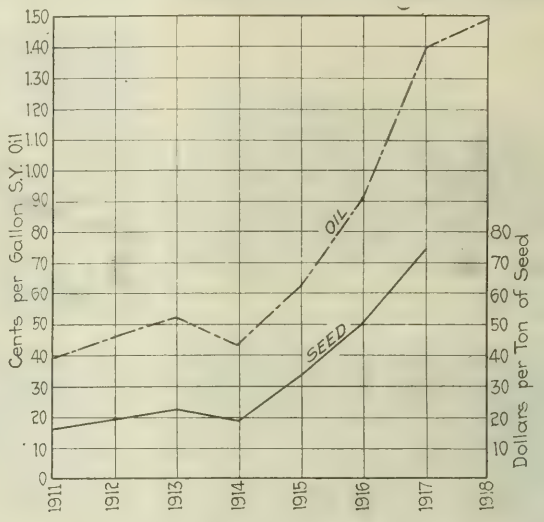

FIG. 5. MARKET VALUES OF SEED AND OIL DURING THE WAR PERIOD

jacket for melting out the soap stock after the oil has been pumped off. The light yellow oil is pumped off into large tanks, such as are shown in Plate 20, where it is allowed to settle and drop out the fine soap, which is still suspended therein.

Fig. 10 shows the relation between free fatty acids in the crude oil and refining losses. These curves were plotted from refinings made all through the season and can be considered as typical. The settled oil is transferred to kettles with heating coils and agitating machinery where a small percentage of fullers earth

FIG. 6. TWO SECTIONS OF THE COTTONSEED

is added and well mixed with the hot oil, which is next pumped through filter presses, as shown in Plate 21. This removes the fullers earth and delivers the clear white oil, which next goes to the deodorizing kettles, after which it comes out almost water white.

The first refineries constructed in this country were mostly frame buildings, which were sufficient to protect the tanks and machinery from the weather. Plate 22 shows one of the oldest plants of the Southern Cotton Oil Co., located at Gretna, La.

Plate 23 shows the refinery of the Southern Cotton Oil Co. at Savannah, taken about 12 yr. ago. The plant has greatly expanded since that time, as shown in the large picture at the head of this article.

Another old plant, built about 1887 by the Olivers at Charlotte, is shown in Plate 24.

With such a demand for the fine quality of oil produced in America, it was necessary to put up plants in Europe. A plant which was in successful operation up to 1916 in Germany is shown on Plate 25. This plant

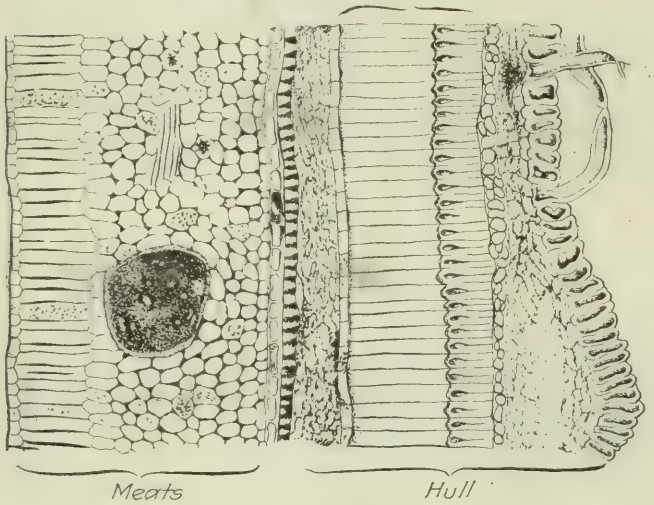

FIG. 7. ENLARGED SECTION OF THE COTTONSEED

rejoices in the euphonious name of the Wesson Gesellschaft für Deutschland mit Beschrenkene Helftung. At the present time, it has somewhat beschrenked. It is of interest in this connection to show how storage tanks are constructed in Germany. The practice prior to the war was to first lay down the bottom of the tank, then set up the top ring on jacks and build the roof, as shown in Plate 26. The tank was gradually raised and new rings put on from the bottom until the bottom ring was finally put on and closed up, as shown in Plate 27. This saved the expense of scaffolding, and, at the same time, kept the men on the ground.

Transportation is an important feature in all industries. It is quite common around oil mills, even today, to see ox teams, as shown in Plate 28. On the face of it, these teams appear rather slow and possibly expensive transportation, but when it is considered that old scrawny steers can be bought very cheap and fattened on meal and hulls at the same time they are making themselves useful as beasts of burden, it is not such a bad proposition as appears on its face. In the early days of the industry, the crude oil was shipped from the mills to refineries in the North in all kinds of cooperage. The speaker has frequently seen lighter loads playing around New York harbor which looked like a package of firecrackers. The barrels, on examination, are found to have been used for kerosene, naphtha, lubricating oils, varnish, whiskey, and what not. In this connection, I remember at the old plant of the N. K. Fairbank Co., 14th St., New York, the night man emptied a lot of oil barrels into a tank to be refined the next morning. The oil in the tank had a flavor never before noticed in crude cottonseed oil. It was found that by mistake a barrel of whiskey had been emptied along with the oil, and there was great lamentation on the part of the steamship company, as well as the men who committed this gross carelessness. Nowadays, crude oil is almost entirely handled in large tank cars, holding as much as 250 bbl. of 400 lb. each. Such a car is shown in Plate 29.

Plate 30 shows the tracks at a modern refinery filled with tank cars ready for unloading. For European shipment, the oil has to be shipped in carefully prepared barrels. Plate 31 shows a steamer being loaded for Europe at our New Orleans refinery.

In a talk on the cotton oil industry, sight must not be lost of the soap stock. The early refineries used to boil this material up with caustic soda and convert it into a soft, yellow soap, which was used more or less by woolen mills. This soap was also boiled down on strong brine until it carried about 30 per cent of water, which made it suitable for export to England, where large quantities were used. About 1886, it was found that by mixing the soap with soda ash, it could be made into very useful washing powder, which has since been advertised extensively by means of the Gold Dust Twins. In the plant of the Southern Cotton Oil Co. at Savannah, the speaker once needed some large soap kettles in a hurry, so he removed the covers from some storage tanks, lagged outside with wood, built a roof over the tops of the tanks, and these were used for some years quite successfully. As these tanks are somewhat of a novelty in the way of soap kettles a picture is shown in Plate 32.

Plates 33 and 34 show the first plant put up in Savannah for the distillation of the black grease made by decomposing the cottonseed soap stock with sulphuric acid. It was more or less of a temporary affair, which met with a sad accident and burned down a couple of years after it was put up.

On account of more or less destructive distillation

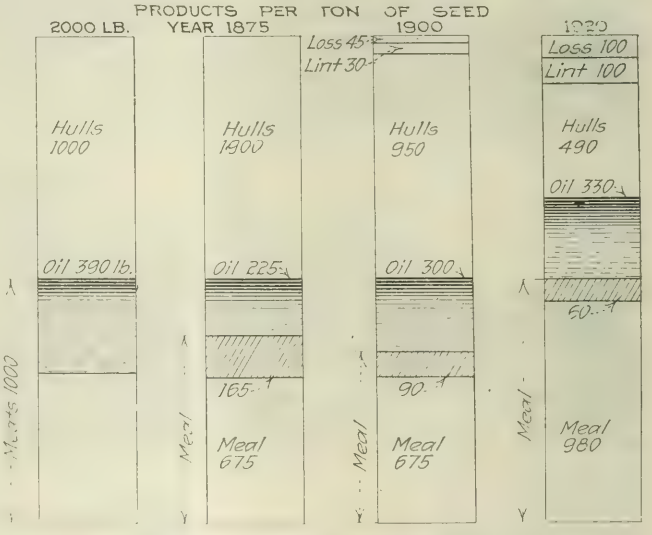

FIG. 8. IMPROVEMENT IN COTTONSEED MILLING, 1875-1920

taking place, owing to the impurities of the black grease, the vapors in the stills were very destructive to copper. Plate 35 shows a copper connection between two of the condensers after it collapsed one day and scared the operators nearly to death.

The modern way of handling soap stock is by means of the Sharples super-centrifuges, which are shown in

53

battery in Plate 36. These recover between 60 and 70 per cent of the entrained oil from the soap stock and reduce the refining loss about 1 per cent. Plate 37 shows one of our latest vegetable shortening plants, located in Chicago. In the manufacturing of vegetable shortening, the oil and hard fat, which, in these days, is almost exclusively hydrogenized cottonseed oil, are mixed in large tanks and then passed over revolving cylinders through which brine from an ice machine is circulated. Plates 38 and 39 show these cylinders in operation. The lard is fed into a trough in which the cylinders set and is chilled on the surface of the cylinder as it revolves. Knives scrape the chilled lard from the surface of the cylinder, in such a way that it continually drops through into a trough in which there is a rapidly revolving shaft covered with blades which break up all the lumps and beat a certain amount of air into the lard. Pumps take the shortening, which is of a creamy consistency, from this trough and pump it directly into the packages.

Plate 40 shows the filling room in the Savannah plant, taken about 15 yr. ago, and Plate 41 shows another view in the packing room. Please notice the large amount of labor present, and also notice that it consists almost entirely of men. Another view of the same work at that time is given in Plate 42, and Plate 43 shows the filling of tubs and large packages. Plate 44 shows the way the product was loaded into cars about 12 or 15 yr. ago.

During the last few years, automatic machinery has been installed and in the words of the song, we "let the women do the work." In Plate 45 girls are shown

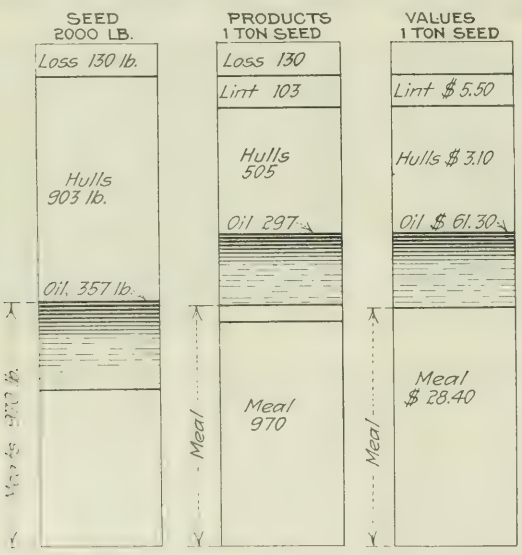

FIG. 9. RESULTS OF MILLING A TON OF SEED

filling large size cans. These are handled altogether by automatic machinery, as is shown in Plate 46, which is a picture of the same filling room shown on a preceding plate. Notice the few hands present and the neat orderly character of the work.

Other views of the same room are given in Plates 47 and 51 and show one of the automatic carriers for handling filled tins. Plate 48 shows the arrangement for filling and automatically soldering oil in cans.

An automatic carrier for loading tubs into cars is shown in Plate 49. This is on the shipping platform and will serve cars along a platform 200 or 300 ft. in length, the only labor needed being to put the tubs on to the carrier and properly pile them in the cars where they are delivered.

In the old days, help around the refineries consisted largely of negroes. Plate 53 shows the gang that used to work in the Memphis refinery of our company.

Plate 52 shows one of the early chemists already

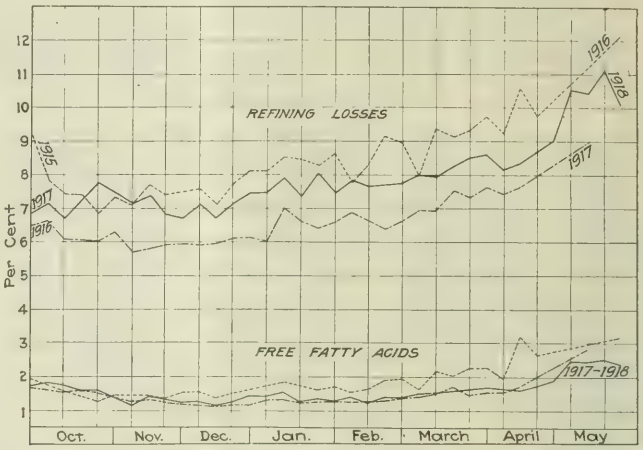

FIG. 10. RELATION BETWEEN FREE FATTY ACIDS IN CRUDE OIL AND REFINING LOSSES

mentioned, and the kind of an outfit used by him for testing his crude oil to see if it was refined properly. This gentleman now occupies an exalted position with one of the large companies.

Plate 50 is another laboratory view, and shows a young chemist grading oil samples for color. In the early days of a certain refinery I know of there was a colored assistant for nearly every white man in the refinery.

A great deal has been said of the wonderful virtues of highly refined cottonseed oil. Eighteen years ago I made some experiments with a certain well-known brand of oil, which has been extensively advertised, believing that the butter fat of cream could be replaced by the oil and successfully worked into ice cream. An experiment tried in my laboratory seemed to prove the theory to be correct, as is shown in Plate 54.

Government Picric Acid Plant for Sale

The ordnance branch of the War Department is offering for sale the buildings, land and equipment comprising the picric acid plant near Little Rock, Ark., which was constructed for war purposes. The buildings which are being offered for purchase include a sulphuric acid plant, a sulphuric concentrator plant, a nitric acid plant, a phenol storage building and a nitrate building, in addition to more than 65 shops, dwellings and small structures.

Not included in the proposed sale, however, are the water supply and gas systems and a power house, which were recently sold to the Arkansas Light & Power Co., providing that company would furnish future purchasers of the remaining buildings and plants with power, gas and water accommodations at prevailing rates.

The plant is readily convertible, officials of the War Department point out, into an oil refinery or fertilizer manufacturing establishment. With the increasing realization on the part of Arkansas and Louisiana cotton and rice growers of the necessity of fertilizer, attention has been called to the particularly favorable location of the plant for the manufacture and distribution of fertilizer.

Recent Chemical and Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

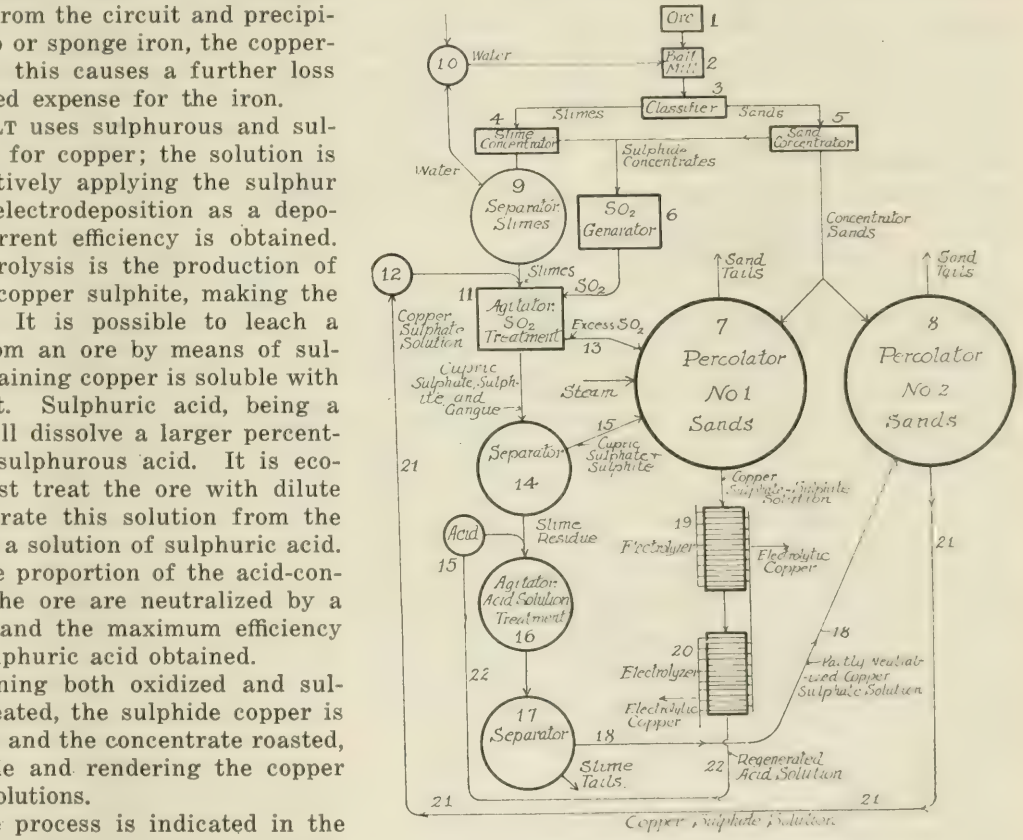
Hydrometallurgical Process for Copper Ores.—In the extraction of copper from its ores by leaching with dilute sulphuric acid the cost of the acid is a major item of expense and, where the ores contain excessive amounts of lime or other acid-consuming constituents, is often prohibitive. The solution of copper is also accompanied by a solution of iron, which is usually associated with oxidized copper ores, and if the copper is to be recovered from the solution by electrolysis, the pressure of excessive amounts of iron results in low current efficiency necessitating the removal of the iron from solution. The usual method is to withdraw a portion of the solution from the circuit and precipitate the copper upon scrap or sponge iron, the copper-free liquor being wasted; this causes a further loss of sulphuric acid and added expense for the iron.

WILLIAM E. GREENAWALT uses sulphurous and sulphuric acids as a solvent for copper; the solution is electrolyzed and by effectively applying the sulphur dioxide liberated in the electrodeposition as a depolarizer an economical current efficiency is obtained. A further result of electrolysis is the production of sulphuric acid from the copper sulphite, making the process self-sustaining. It is possible to leach a portion of the copper from an ore by means of sulphurous acid, but the remaining copper is soluble with difficulty by this reagent. Sulphuric acid, being a more effective solvent, will dissolve a larger percentage of the copper than sulphurous acid. It is economical, therefore, to first treat the ore with dilute sulphurous acid, to separate this solution from the ore and then retreat with a solution of sulphuric acid. By this procedure a large proportion of the acid-consuming constituents of the ore are neutralized by a relatively cheap solvent and the maximum efficiency of the more expensive sulphuric acid obtained.

In case an ore containing both oxidized and sulphide copper is to be treated, the sulphide copper is removed by concentration and the concentrate roasted, supplying sulphur dioxide and rendering the copper soluble in the leaching solutions.

The application of the process is indicated in the accompanying flow sheet. The ore from bin 1 is mixed with water and ground to from 8 to 20 mesh in the ball mill 2, the pulp flows to a classifier 3 and is separated into sand and slime. The sulphide copper is separated from the slimes in the concentrator 4, and from the sand in the concentrator 5, the concentrates being delivered to a roaster 6, designated in the sketch as "SO_2 generator." The concentrator sands are delivered to the percolators 7 and 8. In the flow sheet No. 1 percolator contains fresh sands and No. 2 a charge treated with sulphurous acid or sulphur dioxide only. The slime tailings from concentrator 4 flow to the separator 9 and are dewatered, the water returning to tank 10 and then being fed to the ball mill as desired. The dewatered slimes pass to the agitator 11 for treatment with the SO_2 gases from the roaster 6, together with neutral copper sulphate solution from the treatment of a previous charge in percolator No. 2. A fairly strong gas is preferred for this operation and the excess of sulphur dioxide is introduced into the bottom of percolator No. 1 and is consumed in acting upon the copper and other constituents of the sands that are affected by the gas or its solution in water. The mixture of gangue, cupric sulphate and sulphite, ferrous sulphate and sulphurous acid is separated from the residue in a Dorr thickener 14 and the solution fed to percolator No. 1. The slime residue, now containing the more difficult extractable copper, passes to the acid Dorr agitator 16.

The copper solution from the separator 14 in passing through the sands in the percolator No. 1 issues thoroughly clarified and practically neutral and contains the copper as sulphate and sulphite, ferrous iron and some sulphurous acid. The solution flows to the electrolytic cells, copper being deposited on the cathodes and an equivalent amount of sulphuric acid being liberated at the anodes. This liberated acid reacts with copper sulphite, forming copper sulphate



FLOW SHEET OF PROCESS

and liberating sulphur dioxide, which acts as a depolarizer and also reduces any ferric salts; these in turn act as a depolarizer. The deleterious effect of ferric salts is thus obviated to a large extent.

The solution from the electrolytic cells 19 and 20, which is impoverished in copper and enriched in acid, flows into the acid solution reservoir 15 and thence into the acid agitator 16 and there extracts the copper remaining in the slimes. The pulp flows to a Dorr thickener 17, the slime tails go to waste and the solution to No. 2 percolator, where the remaining acid is consumed in acting on the copper in the sands. The solution from the percolator is now nearly neutral and is delivered to the storage tank 12 and used in treating a fresh batch of slimes in agitator 11 as desired. (1,328,666; Jan. 20, 1920.)

Sodium Fluoride.—To a suspension of sodium fluosilicate in water, a solution of soda ash is added at such a rate that the solution reacts continuously either acid or neutral. The mixture is kept at a temperature of about 205 deg. F. and is agitated constantly until all of the soda ash solution has been added. When the agitation is stopped, the sodium fluoride crystals, being heavier than the silica particles, settle first and may be separated by repeated fractional settling. The crystals contain 98.26 per cent sodium fluoride. (1,324,030; FREDERIC C. BOWMAN, of New York, assignor to General Chemical Co.; Dec. 9, 1919.)

Alkali-Metal Cyanides From Calcium Carbide.—When calcium carbide is heated with sodium (or potassium) chloride or carbonate until the latter fuses and a stream of nitrogen is forced through the mass, alkali-metal cyanide is formed, presumably according to the reactions:

$$2NaCl + CaC_2 + N_2 + C = 2NaCN + CaCl_2 + C$$
$$2Na_2CO_3 + CaC_2 + N_2 + C = 2NaCN + CaCO_3 + C$$

The presence of free carbon in the mass is beneficial if not essential to the formation of the cyanide on a commercial scale. (1,324,119; CHARLES B. JACOBS, of Bloomfield, N. J., assignor by mesne assignments to Air Reduction Co.; Dec. 9, 1919.)

Book Reviews

HENDRICKS' COMMERCIAL REGISTER OF THE UNITED STATES FOR BUYERS AND SELLERS, twenty-eighth annual edition, 1919-1920. 2703 pp. Price, $12.50. New York: S. E. Hendricks Co., Inc.

The constant expansion of the chemical industry is bringing it into closer contact with other manufacturing industries and, as a result, the chemist is looking outside of his own field for new raw materials and new markets. To him, the usefulness of a trade directory such as Hendricks', which covers the entire manufacturing field from raw material to finished product, is self-evident. In spite of the wide range of materials considered, the treatment of each industry is very thorough and the chemist will find that the products of and equipment for the chemical and allied industries have received careful attention. The directory is of particular interest to the sales and purchasing departments. For the former it contains complete lists of all prospective customers and for the latter it shows at a glance the producers of any material required.

An improvement in the new edition is the method of exterior indexing by coloring the front edge red, white and blue to indicate the different main sections of the book. The first section (blue) of 162 pages is the "Index to Trades," in which every product listed in the book is indexed and cross indexed for ready reference. The following section (red) is the main classified trades list and contains 1,813 pages covering over 18,000 different products. In the third section (white), 216 pages are devoted to trade names, arranged alphabetically and followed by the name and address of the manufacturer. An alphabetical list of all the companies referred to in the book, together with their addresses and main lines of business, completes the volume. ALAN G. WICKOFF.

"THE JOURNAL OF THE INSTITUTE OF METALS." Vol. XXII. 428 pp. and 31 plates. Edited by *G. Shaw Scott, M. Sc.* (1919: The Institute of Metals, 36 Victoria St., London, S. W., 1, England. Price 31/6 net.)

This volume contains the technical papers presented before the fall meeting held in Sheffield in September, 1919; the 1919 May Lecture held in London—"Radio-Activity," by Prof. Frederick Soddy; and abstracts of metallurgical literature. This section containing abstracts is by no means the least valuable feature in the eyes of anyone interested in non-ferrous metals; an idea of their excellence may be had if the names of the men who prepared them are listed: The editor, and Messrs. Archbutt, Desch, Hanson, Johnson, Mazzucchelli.

Various contributions of more than usual interest should be cited. Dr. Desch's "Second Report to the Beilby Prize Committee of the Institute of Metals on the Solidification of Metals From the Liquid State" has been reprinted almost entirely in CHEMICAL & METALLURGICAL ENGINEERING, vol. 21, p. 773 (Dec. 24, 1919) under the caption "Effect of Surface Tension on Crystalline Form." Dr. Jeffries' "Note on the Micro-Mechanism of the Aging of Duralumin" is also given in the same volume, p. 553. Messrs. Stead and Spencer's beautiful micrographs of curved crystalline plates contained in their paper "The Ternary Alloys of Tin-Antimony-Arsenic" were utilized in Mr. Seyt's interesting letter on "Contributions by Metallography to L'Art Nouveau" (CHEMICAL & METALLURGICAL ENGINEERING, vol. 21, p. 656).

Other papers are worthy of careful attention by men in special branches of metalworking. Such are "Season Cracking," by W. H. Hatfield and G. L. Thirkell; "Properties and Manufacture of Sterling Silver," by E. A. Smith and Harold Turner; "Britannia-Metal," by F. C. Thompson and F. Orme; "A Typical Bearing Metal," by Miss H. E. Fry and W. Rosenhain; "Molding Sands," by P. G. H. Boswell, and "The Early History of Electro-Silver Plating," by R. E. Leader. All of these papers excited lively discussions in which additional interesting sidelights were disclosed, while two of them are appended by exhaustive bibliographies of the available literature. E. E. THUM.

* * *

SEWAGE DISPOSAL. By *Leonard Kinnicutt, C. E. A. Winslow* and *R. Winthrop Pratt.* 548 pages, illustrated. New York, 1919. John Wiley and Sons, Inc.

The new second edition of this book will be of considerable interest to the large number of engineers familiar with the first edition, and of great value to everyone interested in the general problem of sewage treatment. As a very readable history of the art of treating the collected wastes of civilization brought up to date by the addition of several chapters and supplementary paragraphs, it is a concise, clear presentation of the general problems involved and the various methods of attacking them, with descriptions and tabulations of the results obtained. It should be classed as an intermediate book, as it assumes an elementary knowledge of chemistry and bacteriology, but describes the various processes and accepted theories in a manner that will be clearly understood by the average reader. The details of design are passed over in a general manner to make way for the full discussion of the broader problems of sewage purification within the scope of one volume.

The chapters on Screening, on Sludge Disposal and on Chemical Precipitation have been reconstructed and enlarged. A discussion of the Boston and New Haven studies of the Miles Acid Process has been inserted. The newer processes of two-story tank operation and activated sludge treatment setting forth experience obtained at Cleveland, Chicago and Milwaukee have been discussed in new chapters; and two chapters have been added, one dealing with excretal disposal in the absence of sewerage, and the other dealing with general principles controlling the selection of type and required refinement of operation of sewage treatment plants. It is to be regretted that the valuable tables giving results of operation copied from the first edition were not brought up to date to indicate the effect of time and experience upon the efficiencies of some of the older plants.

The general air of the volume is optimistic concerning the ultimate solution of the sewage problem, and it is pointed out that whereas each newly-discovered process of treatment has been hailed as the end of the search and then has failed to live up to expectations, the knowledge of the subject is constantly increasing, so that the best method of treatment for a given condition may now be selected from a greatly augmented number of processes and special designs. MALCOLM PIRNIE.

Personal

WALTER M. BERRY has been appointed gas engineer for the Bureau of Standards, Washington, D. C., succeeding R. S. McBRIDE, who is now in the Washington, D. C., office of the McGraw-Hill Co.

AUGUSTINE DAVIS has resigned as president of the Davis-Bournonville Co. No successor to the presidency has been elected, and there has been no change in other officers of the company.

BARON G. DE GEER, superintendent of the open-hearth and electric-steel furnaces at Domnarfvet, Sweden, is visiting the steel plants in the United States.

A. H. FAY, mining engineer in charge of accident and certain other statistics for the U. S. Bureau of Mines since the foundation of the Bureau, has resigned to enter private employment.

FREDERIC J. LE MAISTRE has severed his connection with E. I. du Pont de Nemours & Co., and has formed a partnership with Wallace P. Cohoe, of 111 Broadway, New York, under the firm name of Wallace P. Cohoe & Frederic J. Le Maistre, associated consulting chemists and engineers, New York and Philadelphia. The Philadelphia office will be at 810 Bellevue Court Building.

BARON J. MANNERHEIM of Sweden is in the United States as a special representative of the Swedish Pulp Association. He is the guest of Dr. James E. Campbell, president of the Dexter Sulphite Pulp & Paper Co., who is conducting him through the local paper and pulp mills.

R. H. MINTON, recently elected president of the American Ceramic Society, will leave for Europe this month for an extended investigation of conditions in ceramics abroad.

FOREST RUTHERFORD, consulting metallurgist, 120 Broadway, New York City, has returned to New York after making an extended trip through the Southwest.

CASPER SMITH, president of the Smith Chemical & Color Co., New York, has recently returned from a two months' business trip through the United States, extending from coast to coast.

H. L. SULMAN has been awarded the gold medal of the Institution of Mining and Metallurgy, London.

WILLIAM A. WALDIE, for the past few years chief chemist at the Cleveland plant of the Glidden Co., has resigned to associate himself with the Ohio Varnish Co. in the capacity of director of research.

Obituary

JOSEPH M. FLANNERY, president of the Standard Chemical Co., Pittsburgh, Pa., died at his home, Feb. 18. To Mr. Flannery is due the introduction of vanadium in the steel industry, marking an epoch in the advance of steel making.

J. K. PROCTOR, founder and for many years president of the Philadelphia Textile Machinery Co., Philadelphia, Pa., and originator and inventor of the "Proctor" driers, died Feb. 11, of pneumonia.

CHARLES A. WEEKS, the inventor of the Weeks rotating furnace for non-ferrous metals, died on Saturday, Feb. 21. His death was a surprise and shock to friends and associates alike. Previous to the invention of the electric rotating furnace, Mr. Weeks built a number of rotating gas and oil furnaces from which he obtained his original basic ideas covering the subject. He invested his own capital for the manufacture of a furnace of approximately two tons capacity which was installed and operated at the General Electric Co., Schenectady, nearly eight years ago. The reason that the furnace was not immediately placed on the market was because the non-ferrous field had developed only to a small extent—crucibles were cheap and a systematic investigation of losses in melting had not shown up the tremendous losses through volatilization.

Current Market Reports

The Non-Ferrous Metal Market

New York, March 8.—There has been little change since last week's report.

	Cents per Lb.
Copper, electrolytic	19 00
Aluminum, 98 to 99 per cent	33 00
Antimony, wholesale lots	12 00
Nickel, ordinary	43 00
Nickel, electrolytic	45 00
Tin, Straits, spot	64 50
Lead, New York, spot	9 00
Lead, E. St. Louis, spot	8 37½
Zinc, spot, New York	9 30
Zinc, spot, E. St. Louis	9 00

The Iron and Steel Market

Pittsburgh, Pa., March 5, 1920.

Despite the many claims of production of pig iron and steel and the finishing of steel being greatly hampered by transportation conditions, operations continue to grow, although with occasional backsets. The attitude of the iron and steel industry in this matter is in somewhat striking contrast to the sanguine temperament it usually exhibited before the war. Pig-iron production is now at about 90 per cent of capacity, figured against the conservative estimate of 43,000,000 gross tons per annum, or 86 per cent, figured against the more liberal and probably more accurate estimate of 45,000,000 tons capacity.

In some quarters it is being asserted that steel production is not in keeping with pig-iron production, although the ingot report for January showed an 83 per cent production and that pig iron is accumulating at steel works. This, if true, would be extremely awkward for the pig-iron market, which has had the spectacular advance to above $40, and not simply for prompt delivery, but for deliveries extending over the second half of the year. It is decidedly doubtful whether steel products could be sold at this time for delivery throughout the second half of the year at prices that would justify the payment of $40 for the pig iron from which to make the steel.

Inasmuch as iron and steel markets have for years been made partly by psychological influences and not wholly by the actual physical conditions as to supplies and requirements, it is of value to consider the producing trade's mental attitude at this time, as suggested by the above illustrations. In last week's report one aspect of buyers' psychology was referred to—the growing revolt against price dictation by the automobile industry, which does not consume any such percentages of the steel output as to justify

its having much voice in setting prices for the whole market. In the past week the automobile trade has given further exhibitions of its disregard for the cost of materials and its anxiety to secure heavier deliveries. It has paid 12@14c. a lb. for automobile body sheets, leading some sheet mills to buy limited tonnages of sheet bars at $90. A week ago the high point was $80, and the purchases at fancy prices had been made chiefly by middle interests or consumers, for the purpose of making conversion contracts. There are still fairly large deliveries of sheet bars at the March 21 price of $42. The 10-yr. pre-war average was between $25 and $26.

Several large producers have been covering their regular customers for second quarter deliveries at 2.90@3c. for bars, 3@3.10c. for shapes and 3.25@3.50c. for plates, but they are quite indisposed to advertise the fact, some because they have no room for new customers and some, perhaps, because they wish to charge higher prices to buyers not their regular customers.

Market Lacks Real Test

When steel is so scarce and the market exhibits such signs, superficially at least, of there being such buying power, it is altogether without precedent that at the beginning of March producers should be selling only to second quarter. The market lacks the real test, of whether buyers would take hold for third quarter or second half. The Steel Corporation, of course, is sold much farther ahead, but its prices are altogether different.

Export bookings are now very light, the exchange situation and perhaps some other factors preventing there being as large demand in that quarter as formerly. For small lots for prompt shipment, however, export houses are seeking largely in vain.

Conservative estimates are that in the present freight-carrying movement the railroads will take, with a few orders already placed, a total of 40,000 cars. More sanguine estimates place the total at 100,000 cars, but even the larger figure would be less than one-half the number bought in some previous years. Not much more rail buying is expected for this year. As to general construction work, the railroads seem to have little planned. Altogether, the volume of steel likely to be taken by railroads during the remainder of this year is very much smaller than the estimates apparently made by other steel buyers who have been fearful that they would not be able to secure the steel they needed.

In view of the large and increasing production, the growing conservatism of buyers, the smaller export prospects, the quantity of railroad steel to be taken and the disinclination of many investors to engage in construction projects at this time, it seems quite possible that the steel market will assume a new alignment within a few months. There is little if any reason to doubt that there will be a full demand for steel at moderate prices, but some of the prices now going are distinctly immoderate.

Pig Iron

The market is extremely quiet. Bessemer and foundry remain at $42, valley, and there is no particular reason to expect a recession in the near future, but basic, after declining from $43 to $41.50, as recounted a week ago, is by no means strong at the lower figure.

Steel

As noted above, sheet bars have sold at $10 higher, $90, this being in small lots. Producers having regular sheet mill customers have entirely abandoned the idea of covering their customers at $60, but might possibly do $75. Billets are in light demand and still lighter supply, with prices not determined, possibly $55 to $65.

Ferro-Alloys

Small prompt lots of ferromanganuese have been going at $175@$200 and even higher. For second half the regular price is $160, delivered. Spiegeleisen is $57@$60, furnace. Electrolytic ferrosilicon is quoted at $140, delivered, for 75 per cent. Bessemer ferrosilicon is $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, f.o.b. Jackson, Ohio.

The Chemical and Allied Industrial Markets

New York, March 5, 1920.

Buyers are experiencing difficulty in locating supplies in most branches of the chemical market. This condition has been brought about by the heavy exporting of the past few weeks and by certain other details beyond the control of the producers. Many manufacturers are unable to consider any more contracts at present, as their entire production is sold months ahead.

The market continues active in inquiry, with most prices quoted being nominal, as spot material in practically every line is very scarce. *Barium* products have been especially active, and prices have kept pace; producers are sold up and there is very little on the spot market. Quotations ranging from $140@$175 per ton have been received on *barium chloride*. *Soda ash* remains scarce. There were some small spot supplies reported sold at $3 for the light and $3.10 per cwt. on the dense. *Sodium bisulphate*, powdered, has been active during the past week, with quotations of $7@$7.50 per ton for carlots and $8@$10 for less than carlots. Supplies on *caustic potash* at present are short, but the price of 25@32c. per lb. holds firm. *Sodium cyanide*, under the influence of weak demand, dropped to 24@25c. for carlots and 26@27c. per lb. for less than carlots, against 30@32c. and 31@34c. of the previous week. *Caustic soda* still remains under pressure of considerable demand with very little improvement in supplies. Present quotations range from $4.35@$4.60 per cwt. All *ammonium* products, under the influence of the recent coal shortage, remain firm in price. It is reported that the decreasing supply of English *salammoniac* is now exhausted, and a steady increase in this item is predicted by some. *Ammonium chloride*, granular, white, is being listed at 15@16c. for carlots and 17c. per lb. for less than carlots, while *gray* is slightly lower at 13@13½c. per lb. It is impossible to obtain an exact price on *sodium bichromate*, as prices demanded are based entirely on the quantity asked for. Prices as high as 45c. per lb. have been reported.

Coal-Tar Products

There is considerable criticsm among the members of this industry concerning the failure of the proposed bill before the Senate to be passed by that body. General opinion seems to have favored the bill if only for the reason of having some protective measures to check the growth of the German dye industry in the United States and at the same time encourage our domestic producers to meet the demands of this country. Under the influence of this unsettled condition the market has remained quiet, with action in price being displayed by only a few of the items which are feeling an acute shortage. *Dimethylaniline* is off the spot market and producers are contracted for several months ahead. A nominal quotation of 95c.@$1.20 per lb. has been received. The scant supply of the past few weeks on *H acid* has not improved to any extent and the quotation of $1.60@$1.75 per lb. still holds firm. *Salicylic acid*, tech., holds firm under the present demand at 43@45c. per lb., while U. S. P., with a slightly heavier demand, is listed at 55c.@60c. per lb.

Waxes

There has been a slight increase over the usual amount of business in the *wax* market during the past week. Supplies on all grades of *carnauba* are cramped. Nominal quotations have been received, on No. 1, 80@88c. per lb., No. 2 regular, 65@78c., and No. 3, North Country, 46@48c. *Paraffines* remain firm throughout, with a continued heavy foreign demand especially from the Far East.

Naval Stores

Turpentine is again on the upward trend due to shortage of supplies in New York, and present market is about $1.99 per gal. *Rosins* have come up slightly under the pressure of the heavy buying that was felt while prices were down. K-N grades are listed at $18.50@$21.50 and B-D at $17@$18.50. Foreign inquiry in this market has been at a standstill during the past few weeks and those engaged in this trade are anxiously awaiting a more favorable exchange.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0.60 – $0.65
Acetone	lb.	$0.16 – $0.20	.21 –
Acid, acetic, 28 per cent	cwt.	2.75 – 3.00	3.00 – 3.25
Acetic, 56 per cent	cwt.	6.00 – 6.50	7.00 – 7.50
Acetic, glacial, 99½ per cent, carboys	cwt.	12.00 – 12.50	13.50 – 15.50
Boric, crystals	lb.	.14½ – .15½	.15½ – .16½
Boric, powder	lb.	.14½ – .15	.15 – .16
Hydrochloric	lb.	.08 –	.09 – .10

Arsenic, oxide, lumps (white arsenic)	lb.	—	.10¾ – .11
Arsenic, sulphide, powdered (red arsenic)	lb.	.23 – .24	—
Barium chloride	ton	140.00 – 150.00	160.00 – 170.00
Barium dioxide (peroxide)	lb.	.26 – .27	.28 – .30
Barium nitrate	lb.	.11 – .12	.13 – .14
Barium sulphate (precip.) (blanc fixe)	lb.	.03 – .03½	.05½ – .06
Bleaching powder (see calcium hypochlorite)		—	—
Blue vitriol (see copper sulphate)		—	—
Borax (see sodium borate)		—	—
Brimstone (see sulphur, roll)		—	—
Bromine	lb.	.90 – .95	—
Calcium acetate	cwt.	2.00 – 2.05	2.10 –
Calcium carbide	lb.	—	.04¾ – .05
Calcium chloride, fused, lump	ton	20.00 – 25.00	30.00 – 40.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02¼
Calcium hypochlorite (bleaching powder)	cwt.	— 3.50	4.00 – 4.50
Calcium peroxide	lb.	—	1.50 – 1.70
Calcium phosphate, monobasic	lb.	—	.75 – .80
Calcium sulphate, pure	lb.	—	.25 – .30
Carbon bisulphide	lb.	.06 – .08	.09 – .10
Carbon tetrachloride, drums	lb.	.10¾ – .11	.12 – .15½
Carbonyl chloride (phosgene)	lb.	—	.80 – 1.05
Caustic potash (see potassium hydroxide)		—	—
Caustic soda (see sodium hydroxide)		—	—
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.08 –
Chloroform	lb.	.28 – .29	.30 – .31
Cobalt oxide	lb.	—	2.00 – 2.05
Copperas (see iron sulphate)		—	—
Copper carbonate, green precipitate	lb.	.27 – .28	.29 – .31
Copper cyanide	lb.	—	.65 – .70
Copper sulphate, crystals	lb.	.08¼ – .09	.09 – .09½
Cream of tartar (see potassium bitartrate)		—	—
Epsom salt (see magnesium sulphate)		—	—
Formaldehyde, 40 per cent	lb.	—	.45 – .65
Glauber's salt (see sodium sulphate)		—	—
Glycerine	lb.	—	.24½ – .26
Iodine, resublimed	lb.	—	4.10 – 4.30
Iron oxide, red	lb.	—	.03 – .20
Iron sulphate (copperas)	cwt.	1.20 –	1.25 – 1.75
Lead acetate, normal	lb.	.12 – .13	.14 – .23
Lead arsenate (paste)	lb.	—	.13 – .17
Lead nitrate, crystals	lb.	—	.70 – .80
Litharge	lb.	.11½ – .12¼	.12½ – .13
Lithium carbonate	lb.	—	1.50 –
Magnesium carbonate, technical	lb.	—	.13 – .14½
Magnesium sulphate, U. S. P	100 lb.	3.75 – 3.45	3.50 – 3.75
Magnesium sulphate, commercial	100 lb.	3.00 – 3.10	3.10 – 3.20
Nickel salt, double	lb.	.14 –	.15 –
Nickel salt, single	lb.	.12½ – .13	.17 –
Phosgene (see carbonyl chloride)		—	—
Phosphorus, red	lb.	—	.60 – .65
Phosphorus, yellow	lb.	—	.35 – .37
Potassium bichromate	lb.	.32 – .33	.34 – .37
Potassium bitartrate (cream of Tartar)	lb.	—	.56 – .60
Potassium bromide, granular	lb.	—	.50 – .65
Potassium carbonate, U. S. P	lb.	.60 –	.65 – .70
Potassium carbonate, crude	lb.	.26 – .27	.28 – .30
Potassium chlorate, crystals	lb.	.16 – .20	.21 –
Potassium hydroxide (caustic potash)	lb.	.25 – .32	.35 – .42
Potassium iodide	lb.	—	3.35 – 3.60
Potassium nitrate	lb.	.19 –	.21 –
Potassium permanganate	lb.	—	$0.65 – $0.95
Potassium prussiate, red	lb.	1.00 – 1.05	1.10 – 1.20
Potassium prussiate, yellow	lb.	—	.40 – .70
Potassium sulphate	ton	$225.00 –	—
Rochelle salts (see sodium potas. tartrate)		—	—
Salammoniac (see ammonium chloride)		—	—
Sal soda (see sodium carbonate)		—	—
Salt cake (sodium sulphate)	ton	18.00 – 21.00	—
Silver cyanide	oz.	—	1.25 –
Silver nitrate	oz.	—	81 – 82¼
Soda ash, light	100 lb.	2.50 – 2.60	— 3.00
Soda ash, dense	100 lb.	2.70 – 2.75	— 3.10
Sodium acetate	lb.	.06½ – .07	.07 – .08
Sodium bicarbonate	100 lb.	2.40 –	2.75 – 3.00
Sodium bichromate	lb.	.33 – .34	.35 – .36
Sodium bisulphate (nitre cake)	ton	7.00 – 7.50	8.00 – 10.00
Sodium bisulphite Powered	lb	.05½ – .06½	.07 – .07½
Sodium borate (borax)	lb.	.08½ – .08¾	— .09
Sodium carbonate (sal soda)	100 lb.	1.35 – 1.40	1.50 – 1.75
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.24 – .25	.26 – .27
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	—	4.85 – 5.25
Sodium hyposulphite	lb.	—	.03¾ .04
Sodium molybdate	lb.	2.50 –	3.25 –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	.15 – .17	— .18
Sodium peroxide, powdered	lb.	—	.30 – .32
Sodium phosphate, dibasic	lb.	.03½ – .04½	.04½ – .05
Sodium potassium tartrate (Rochelle salts)	lb.	.40 – .42	.43 – .45½
Sodium prussiate, yellow	lb.	.23 – .29	.30 – .40
Sodium silicate, solution (40 deg.)	lb.	.01½ – .02	.02 – .02¼
Sodium silicate, solution (60 deg.)	lb.	.02¼ – .03	.05 – .06
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.15 – 1.50	1.60 – 2.00
Sodium sulphide, crystal, 60–62 per cent (conc)	lb.	—	.05 – .06
Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 –
Sulphur chloride	lb.	.05¾ –	.06 –
Sulphur, crude	ton	22.00 –	—
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½ –	.46 – .50
Tin oxide	lb.	.50 – .60	.65 –
Zinc carbonate, precipitate	lb.	—	.20 –
Zinc chloride, gran	lb.	.13 –	.13½ – .15
Zinc cyanide	lb.	.49 –	.50 –
Zinc dust	lb.	.11¾ – .12½	.13 – .15
Zinc oxide, dry American	lb.	—	.09½ – .12
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

*Nominal quotations.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 — $1.10
Alpha naphthol, refined	lb.	1.40 — 1.60
Alpha naphthylamine	lb.	.40 — .50
Aniline oil, drums extra	lb.	.34 — .45
Aniline salts	lb.	.42 — .50
Anthracine, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde (f.f.c.)	lb.	2.00 — 2.10
Benzidine, base	lb.	1.25 — 1.35
Benzidine, sulphate	lb.	1.00 — 1.15
Benzoic acid, U.S.P.	lb.	.90 — 1.10
Benzoate of soda, U.S.P.	lb.	.80 — 1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 — .36
Benzol, 90%, in drums (100 lb.)	gal.	.25 — .29
Benzyl chloride, 95-97%, refined	lb	.35 — .40
Benzyl chloride, tech	lb.	.25 — .35
Beta naphthol benzoate	lb.	.50 — .55
Beta naphthol, sublimed	lb.	.65 — .80
Beta naphthol, tech	lb.	.45 — .55
Beta naphthylamine, sublimed	lb.	2.25 — 2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 — 1.10
Cresylic acid, 95-97%, dark, in drums	gal	.85 — 1.00
Cresylic acid, 50%, first quality, drums	gal	.60 — .70
Dichlorbenzol	lb.	.07 — .10
Diethylaniline	lb.	1.40 — 1.50
Dimethylaniline	lb.	.95 — 1.20
Dinitrobenzol	lb.	.26 — .37
Dinitroclorbenzol	lb.	.25 — .30
Dinitronaphthaline	lb	.45 — .55
Dinitrophenol	lb	.32 — .36
Dinitrotoluol	lb	.38 — .45
Dip oil, 25%, tar acids, car lots, in drums	gal	.38 — .40
Diphenylamine	lb.	.55 — .65
H-acid	lb.	1.60 — 1.75
Metaphenylenediamine	lb.	1.15 — 1.80
Monochlorbenzol	lb.	.12 — .15
Monoethylaniline	lb.	1.50 — 1.75
Naphthaline crushed, in bbls. (250 lb.)	lb	.06 — .08
Naphthaline, flake	lb.	.07 — .08
Naphthaline, balls	lb.	.08½ — .10
Naphthionic acid, crude	lb.	.75 — 1.25
Nitrobenzol	lb.	.14 — .19
Nitro-naphthaline	lb.	.30 — .35
Nitro-toluol	lb	3.75 — 4.25
Ortho-amidophenol	lb.	.15 — .20
Ortho-dichlor-benzol	lb.	.80 — 1.25
Ortho-nitro-phenol	lb.	.25 — .40
Ortho-nitro-toluol	lb.	.25 — .45
Ortho-toluidine	lb	2.50 — 3.50
Para-amidophenol, base	lb	2.50 — 3.25
Para-amidophenol, HCl	lb	.12 — .18
Para-dichlor-benzol	lb	1.00 — 1.35
Paranitraniline	lb.	1.35 — 1.50
Para-nitro-toluol	lb	2.15 — 3.00
Paraphenylenediamine	lb	1.75 — 2.50
Paratoluidine	lb	.60 — .70
Phthalic anhydride	lb	.12 — .25
Phenol, U. S. P., drums (dest.), (240 lb.)	gal	2.00 — 2.50
Pyridin	lb	3.75 — 4.50
Resorcin, technical	lb	6.50 — 6.75
Resorcin, pure	lb.	.43 — .45
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.55 — .60
Salicylic acid, U. S. P.	lb.	.90 — .95
Salol		

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.22 —	$0.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42 —	$0.45
Beeswax, refined, yellow	lb.	.47 —	.48
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1. (nominal)	lb.	.80 —	.88
Carnauba, No. 2, regular (nominal)	lb.	.65 —	.78
Carnauba, No. 3, North Country (nominal)	lb.	.46 —	.48
Japan	lb.	.17 —	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	..... —	.07½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.10½
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.08
Paraffine waxes, refined, 128-130 m.p.	lb.	.11 —	.11¼
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.14
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist.	gal	.....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal	.48
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal	1.60
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.00	—$18.50
Rosin E-I	280 lb.	18.05	— 18.75
Rosin K-N	280 lb.	18.50	— 21.50
Rosin W. G.-W. W.	280 lb.	21.50	— 24.25
Wood rosin, bbl.	280 lb.	15.50	— 17.50
Spirits of turpentine	gal.	.....	— 1.99
Wood turpentine, steam dist.	gal.	.....	— 1.93
Wood turpentine, dest. dist.	gal.	.....	— 1.85
Pine tar pitch, bbl.	200 lb.	8.50	— 8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	— 14.75
Retort tar, bbl.	500 lb.	15.00	— 15.25
Rosin oil, first run	gal.	.93	— .95
Rosin oil, second run	gal.	.96	— .97
Rosin oil, third run	gal.	1.10	— 1.15
Rosin oil, fourth run	gal.	.....	— 1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.42½ —	$0.44
Upriver coarse	lb.	.31½ —	.35
Upriver caucho ball	lb.	.31½ —	.34½
Plantation—First latex crepe	lb.	.40½ —	.49
Ribbed smoked sheets	lb.	.46 —	.48
Brown crepe, thin, clean	lb.	.41 —	.43
Amber crepe No. 1	lb.	.45 —	....

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.19 —	$0.20
Castor oil, AA, in bbls.	lb.	.20 —	.23
China wood oil, in bbls.	lb.	.23½ —	.25½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18½ —	.19½
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½ —	.23
Corn oil, crude, in bbls.	lb.	.19 —	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	17.50 —	18.00
Cottonseed oil, summer yellow	lb.	19.00 —	20.00
Cottonseed oil, winter yellow	lb.	.24½ —	.25½
Linseed oil, raw, car lots	gal.	1.77 —	
Linseed oil, raw, tank cars	gal.	1.72 —	
Linseed oil, boiled, car lots	gal.	1.80 —	
Olive oil, commercial	gal.	2.50 —	3.00
Palm, Lagos	lb.	.16 —	.16½
Palm, bright red	lb.	.15½ —	.17½
Palm, Niger	lb.	.15 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.22¾ —	.24
Peanut oil, refined, in bbls.	lb.	.27 —	.28
Rapeseed oil, refined in bbls.	gal	1.70 —	
Rapeseed oil, blown, in bbls.	gal	1.60 —	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.18½ —	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.16¾ —	.20

FISH

Winter pressed Menhaden	gal.	$1.15 —	...
Yellow bleached Menhaden	gal.	1.20 —	...
White bleached Menhaden	gal.	1.22 —	....
Blown Menhaden	gal	1.28 —	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00	—$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.04½ —	.05½
Blanc fixe, pulp	ton	30.00 —	50.00
Casein	lb.	.16 —	.18
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	.04½ —	.06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar	ton	13.50 —	18.00
Fluor spar, acid grade, lump, f.o.b. mines	net ton	30.00 —	45.00
Fluor spar, acid grade, ground, f.o.b. mines	net ton	50.00 —	52.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00
Graphite, crucible, 85% carbon content	lb.	..... —	.07½
Graphite, crucible, 86% carbon content	lb.	..... —	.08
Graphite, crucible, 87% carbon content	lb.	..... —	.07
Graphite, crucible, 88% carbon content	lb.	..... —	.08½
Graphite, crucible, 89% carbon content	lb.	..... —	.08¼
Graphite, crucible, 90% carbon content	lb.	..... —	.09
Graphite, crucible, 91% carbon content	lb.	..... —	.08½
Graphite, crucible, 92% carbon content	lb.	..... —	.09½
Graphite, crucible, plus 92%	lb.	..... —	.12
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, orange, fine, nominal	lb.	1 55 —	1.60
Shellac, orange, superfine	lb.	1.65 —	1.70
Shellac, A. C. garnet	lb.	1.30 —	1.35
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	16.00 —	60.00
Talc, imported	ton	60.00 —	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	38-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	33-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	45-50 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.22
Ferro-manganese, 70-80% Mn	gross ton	160.00 —	170.00
Spiegeleisen, 16-20% Mn	gross ton	50.00 —	60.00
Ferro-molybdenum, per lb. of Mo	lb.	2.50 —	2.75
Ferro-silicon, 50%	gross ton	85.00 —	95.00
Ferro-silicon, 75%	gross ton	150.00 —	175.00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	.90 —	1.10
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50 —	7.50

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.60 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	.....
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	.....
Petroleum coke, refinery, Atlantic seaboard	net ton	..... —	14.00
Fluor spar, gravel, f.o.b. mines	net ton	..... —	25.00
Manganese ore, 45% Mn and over	unit	.75 —	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00 —	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	9.00 —	15.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	7.50 —	10.00
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	.....
Rutile, 95% TiO_2	lb.	.11 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

*Government prices.

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

MIDDLETOWN — Wesleyan University, 374 High St., is having plans prepared for the construction of a 2-story chemical laboratory. Estimated cost, $500,000. Henry Bacon, 101 Park Ave., New York City, archt. and engr.

Idaho

OROFINO—The Crustaline Lime Co. is in the market for a 125-ton daily capacity rotary kiln, etc. Total estimated cost, $100,000.

Illinois

CHICAGO—The Steel Sales Corp., 129 South Jefferson St., has purchased a site at Crawford Ave. and 35th St. and plans to build a 1-story, 400 x 600-ft. steel fabrication plant on same. Estimated cost, $250,000.

HIGHLAND PARK—The city is having plans prepared and estimates submitted for the construction of a filtration plant, extensions to distribution system and installation of a 5,000,000-gal. additional pumping equipment. Alvord Burdick, 8 South Dearborn St., Chicago, engr.

KEWANEE—The city is having a study made of its problem of sewage disposal. Alvord & Burdick, 8 South Dearborn St., Chicago, engrs.

ROCKFORD—The city is having plans prepared for the construction of an intercepting sewer and a disposal plant. Alvord & Burdick, 8 South Dearborn St., Chicago, engrs.

Indiana

BLOOMINGTON—The city is having plans prepared for the enlargement of present sewage disposal plant. Alvord & Burdick, 8 South Dearborn St., Chicago, engrs.

KOKOMO—The Pittsburgh Plate Glass Co., Vaile Ave., has awarded the contract for the construction of new buildings and extensions to its plant, here, to Stone & Webster, 120 B'way, New York City. Estimated cost, $2,000,000. J. W. Buzzell, contract mgr.

SEYMOUR—The Water Co. plans to improve power station. Improvements consist of a new sedimentation basin of 2,000,000-gal. capacity and rebuilding of the steam plant.

Iowa

AMES—The city had plans prepared for the construction of a sewage disposal plant, consisting of pumping plant, Imhof tank, sludge bed and trickling filters, etc. Estimated cost, $100,000. P. E. Hopkins, mgr. dept. of engr.

OAKDALE—The Bd. of Control, State House, Des Moines, will soon award the contract for the construction of a 2-story laboratory in connection with the State Sanatorium, here. H. F. Liebbe, State House, Des Moines, archt.

Kansas

COFFEYVILLE—The Kansas Oil Refining Co. plans to build additions to its oil refinery, 2 mi. from here. Estimated cost, $500,000. H. R. Heal, genl. mgr.

Louisiana

NEW ORLEANS—The New Orleans Gas Light Co., Bayonne and Common Sts., has awarded the contract for the installation of a new purification system in its proposed plant, to the Western Gas Constr. Co., Fort Wayne, Ind. Estimated cost, $312,000.

NEW ORLEANS—The Surgical Supply Co., 1425-1427 Canal St., is in the market for buffing machines, nickel plating equipment, etc. John A. Moran, secy. and treas.

Maryland

CANTON (Baltimore P. O.)—The Baltimore Copper Smelting & Rolling Co., 4th Ave. and 5th St., had plans prepared for the construction of a 1-story, 204.3 x 329.8-ft. copper rolling mill at 1st and 2nd Sts. and 3rd Ave. Estimated cost, $130,000.

Massachusetts

CAMBRIDGE—Lever Bros. Co., Portland St., is having plans prepared for the construction of a 6-story mfg. plant addition. C. Timain, 201 Devonshire St., Boston, archt. and engr.

CHESTNUT HILL (Boston P. O.) — Boston College, University Heights, is having plans prepared for the construction of a 5-story chemical and physical laboratory on the campus, here. Maginnis & Walsh, 100 Boylston St., Boston, archts. and engrs.

LEE—The Smith Paper Co. has awarded the contract for the construction of a 2-story, 50 x 140-ft. paper mill, here, to the Lynch Bros. Brick Co., Holyoke. Estimated cost, $60,000.

WEST SPRINGFIELD (Springfield P. O.) —The Gilbert & Barker Mfg. Co., Cold Springs Ave., will soon award the contract for the construction of 5 factory buildings, including a 1-story, 80 x 400-ft. brass foundry, 1-story, 40 x 80-ft. zinc building, a 1-story, 160 x 230-ft. sheet metal building, etc. Estimated cost, $750,000. McClintock & Craig, 33 Lyman St., Springfield, archts. and engrs.

Michigan

DETROIT—The General Testing Laboratories, analytical and research chemists, 97 Woodward Ave., plan to enlarge their plant and are in the market for equipment for general physicians' analytical work and bacteriology. J. A. Wolf, genl. mgr.

MARYSVILLE — Smith, Hinchman & Grylls, archts. and engrs., 710 Washington Arcade, Detroit, will soon award the contract for the construction of a 1- and 2-story, 380 x 420-ft. foundry at Michigan Ave. and Cuttle Rd., for the General Aluminum & Brass Co., Boulevard and St. Aubin Sts., Detroit. Estimated cost, $500,000.

MILFORD—The village is making surveys and plans and submitting estimates for the construction of a complete sewer system, including vitrified sewers and disposal works. Estimated cost, $100,000. C. W. Hubbell, 2348 Penobscot Bldg., Detroit, engr.

PLEASANT RIDGE (Detroit P. O.)— The village plans to construct complete storm water and sanitary sewer systems with sewage disposal works in the streets in the vicinity of Woodward Ave. C. W. Hubbell, 3248 Penobscot Bldg., engr.

Minnesota

DULUTH—The Northwest Products Co., c/o Marshall Wells Co., Lake Ave., has awarded the contract for the construction of a 1-story, 44 x 60-ft. paint mfg. plant, to Jacobson Bros., 410 Columbia Bldg. Estimated cost, $15,000.

Nebraska

LINCOLN—The city, together with four suburbs, is having a report prepared for the construction of additional intercepting sewers and sewage disposal plant. Alvord & Burdick, 8 South Dearborn St., Chicago, engrs.

New Jersey

BAYONNE—The Nitrate Agencies Co. will build a factory on West 1st St. Estimated cost, $50,000.

New York

BUFFALO—The General Drop Forge Co., 1738 Elmwood Ave., is having plans prepared for the construction of a 1-story, 100 x 100-ft. heat-treating plant. Estimated cost, $75,000. Ernest McGeorge, 1900 Euclid Ave., Cleveland, O., archt. and engr.

NEW YORK—The Bd. of Purchase, Municipal Bldg., will receive bids until March 12 for furnishing and delivering copper sulphate to the dept. of Water Supply, Gas and Electricity. Grover A. Whalen, chairman.

NEW YORK—The Natl. Gum & Mica Co., 12 West End Ave., will build a 25 x 100-ft. factory on West End Ave. Work will be done by day labor. Noted Feb. 4.

SALAMANCA—The Kendall Refining Co., Kendall Ave., Bradford, Pa., plans to construct a 2-story, 30 x 40-ft. office and storage building and three steel, 12,000-gal. tanks, on Broad St. Estimated cost, $50,000-$60,000.

Ohio

ASHLAND — R. A. Davis, Mayor and Pub. Serv. Dir., City Hall, will receive bids until March 16 for the construction of a filter building and installation of equipment in same. Noted Feb. 18.

CLEVELAND—The Aetna Rubber Co., 815 East 79th St., plans to construct a 1- and 2-story, 100 x 130-ft. factory. Estimated cost, $100,000. H. Kappler, mgr.

Pennsylvania

HOLMSBURG JUNCTION (Philadelphia P. O.)—The Precision Grinding Wheel Co., manufacturer of grinding wheels, 1215 Filbert St., Philadelphia, is building the first unit of a modern plant on the New York Division of the Pennsylvania R.R. Complete equipment will be installed in same. Grinding wheels made of synthetic corundum or crystallized aluminum oxide, also silicon carbide, will be manufactured by the vitrified, shellac, silicate and rubber processes. H. A. Plusch, mgr.

SPRINGDALE—The West Pennsylvania Power Co. is receiving bids for furnishing filter equipment for the proposed 1,000,000-gal. filtration plant. Chester & Fleming, Union Bk. Bldg., Pittsburgh, engrs.

STEELTON—C. P. Turner, engr., Bethlehem Steel Co., is building a 2-story, 50 x 100-ft. laboratory, for the Bethlehem Steel Co. Estimated cost, $50,000. Bissel & Sinkler, Otis Bldg., Philadelphia, archts.

Texas

ORANGE—The Mogul Oil Refining Co. plans to build a 10,000-bbl. refinery. Estimated cost, $1,000,000.

Wisconsin

CARROLLVILLE—H. J. Esser, archt., Camp Bldg., Milwaukee, will soon award the contract for the construction of a 3-story, 375 x 500-ft. food factory, here, for the United States Glue Co. Estimated cost, $500,000.

MILWAUKEE—The Sewage Comn. will receive bids until April 8 for furnishing and installing a fine screen plant for the sewage disposal plant. T. Chalkley Hatton, chief engr.

RACINE—The Racine Mfg. Co., 6th and Mead Sts., is receiving bids for the construction of a 1-story, 100 x 150-ft. dry kiln on Mead St.

Quebec

MONTREAL—The Dominion Glass Co., Wellington St., is in the market for a platinum evaporating dish of a 125 c.c. capacity to be used for laboratory work. C. K. McLeod, chemist.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will hold a meeting on March 26, the subject of which is "Peace Uses for War Products."

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theatre: "Helium," Monday, March 29, at 4 P.M., Dr. R. B. Moore, chief

chemist, U. S. Bureau of Mines (*Lantern*); "Romance of Leather Making," Tuesday, April 13, at 4 P.M., E. A. Brand (*Lantern*); "Water Supply and Drainage in War Cantonments," Wednesday, April 21, at 4 P.M., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers Process), Thursday, April 29, at 4 P.M., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 P.M., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Fire-foam," Friday, May 14, at 4 P.M., F. A. Epps, chief engineer, the Foamite Fire-foam Co. (*Experimental, cinema and lantern*).

THE FARADAY SOCIETY (London) will hold a meeting on March 23, at which there will be a general discussion on "Basic Slag From the Metallurgical and Agricultural Standpoints."

THE INSTITUTE OF METALS will hold its annual general meeting March 11 and 12 at the Institute of Mechanical Engineers, Storey's Gate, Westminster, S. W. 1, London, England.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Industrial Notes

THE GLIDDEN CO. of Cleveland has taken over the Yarnan Rosin & Turpentine Co. of Brunswick, Ga., and Gulfport, La.

THE AMERICAN METALLURGICAL CORP., Franklin Trust Bldg., Philadelphia, Pa., announces the opening of an office at Credland Chambers, 111 Queen St., Sheffield, England, the title of the headquarters there to be the Midland Metallurgical Ltd. The foreign headquarters will be under the direction of Beecroft & Partners, an old and well known engineering organization of Staffordshire, England, G. C. Castle to be directly in charge. The foreign headquarters will carry on the same type of work as carried on by the American Metallurgical Corp., namely, covering the entire field of electrometallurgy and chemical developments.

R. C. GOSROW, metallurgical engineer and electrometallurgist, announces the establishment of his office at 701 Claus Spreckels Bldg., San Francisco, Cal., to engage in consulting work on the metallurgy of iron, steel, ferro-alloys and ore-reduction processes, the heat treatment of steel and steel improvement, the design, construction and operation of electric furnaces, electric furnace processes. He will also be Western representative for the Pittsburgh Furnace Co. of Milwaukee, Wis.

C. R. HAYWARD, assistant professor of metallurgy at the Massachusetts Institute of Technology, and H. M. Schleicher, formerly director of the Central Research Laboratory of the U. S. Smelting, Refining & Mining Co., have opened an office under the name of Hayward & Schleicher at 69 Massachusetts Ave., Cambridge, Mass., as research metallurgists.

THE WILKENS-ANDERSON CO., Chicago, Ill., announces that W. G. Calkins of Detroit, Mich., has developed a new combustion boat for the determination of carbon in steel, known as the NoNoX combustion boat, which is a practically non-oxidizing metallic boat, combining the refractory qualities of non-metallic boats such as porcelain, silica, etc., with the strength and shock resisting properties of a metal. This company also announces that Herbert S. Wilson, chief chemist of the Collons Safety Razor Co., has devised the Wilson carbon determination apparatus, which is a new departure.

THE MONO CORP. OF AMERICA, 48 Coal & Iron Exch., Buffalo, N. Y., announces that it has purchased the entire stock of Mono apparatus and accessories from the F. D. Harger Co., Buffalo, N. Y. This includes all rights for the manufacture and sale of its various types of Mono apparatus for the automatic analysis of CO_2, CO, O, H, SO_2, N, Cl, etc. F. D. Harger has not severed his connection, but will serve as general manager of the new corporation. A service and inspection department, connected with the laboratory, is now in operation and a competent chemical engineer in charge. Capable erectors will be placed at the disposal of customers in connection with the erection of new work and regular inspection trips will be arranged to visit existing installations with a view to bringing about closer co-operation between the customer and the corporation.

GEORGE B. CAREY AND ASSOCIATES of Lexington, Ky., have purchased the Chinn Mineral Co.'s calcite and baryta fields at Muncy's Landing, near Harrodsburg, Ky., and plan to start working them at once.

THE SHERWIN-WILLIAMS CO. has recently purchased the Acme White Lead & Color Works of Detroit and Frank Hemingway & Co., manufacturers of chemicals, dyes and insecticides, with plants at New York and Bound Brook, N. J. This old established Cleveland concern owns lead and zinc mines, operates its own smelter, lead corroding plants, lithopone plant, linseed oil mill, dye and color plants and can factory. It owns the Sherwin-Williams Co. of Canada, Louis Berger & Sons, Ltd., of London and Louis Berger & Son and the Sherwin-Williams Co. of Australia.

THE ESSEX ANILINE WORKS, INC., will remove its present main offices at 39 Oliver St. to 88 Broad St., Boston, Mass. The laboratory will remove to the works at South Middleton, Mass., and shipments of dyestuffs will be made from that point.

THE MICHIGAN SMELTING & REFINING Co., Detroit, Mich., announces that at the annual meeting, held in the administration offices, John R. Searles was elected president and general manager to succeed the late Joseph Sillman, founder of the business. Other officers and directors were elected as follows: Norman Sillman, vice-president; Henry Levitt, secretary and treasurer; directors: John R. Searles, Emory W. Clark, Walter P. Crysler, Leo M. Butzel, Henry Levitt, Norman Sillman and Chas. O. Patch.

THE PRECISION GRINDING WHEEL CO., Philadelphia, Pa., has recently secured the services of H. A. Plusch as secretary and factory manager, and A. S. Vane has been made president and manager.

THE MATHIESON ALKALI WORKS, INC., has established its headquarters in New York City, and hereafter it will sell all of its products direct, instead of, as heretofore, disposing of the greater part through Arnold Hoffman Co., Inc., of Providence, R. I. The company expects to occupy its permanent executive and general offices at 25 West 43rd St., New York, on and after March 5. Accordingly on and after that date, all communications should be sent to that address.

J. C. HENRIQUES and M. A. STONE, JR., have organized a staff of consulting engineer, and formed the Engineering & Appraisal Co., Inc., with offices at 103 Park Ave., New York, opposite Grand Central Station. Their field of work will cover the design and construction of mills, factories, power plants and chemical works; the design and development of special machinery and the formulation of commercial propositions on which the formation of new manufacturing corporations may be based. The company is prepared to design and construct industrial plants for every purpose. Members of the staff are specialists in the utilization of waste steam and the application of steam to chemical and other processes; the derivation of oxygen, nitrogen and other gases; the application of refrigeration and cold storage; the evaporation and concentration of solutions and liquids, and the design and development of special machinery.

THE ADVERTISING ENGINEERS, INC., 50 Union Sq., New York City, has opened an office for the purpose of carrying on the business of counselors and complete service for advertisers of engineering and technical products. Curtis F. Columbia will act as Eastern manager. He was formerly publicity engineer for the New Jersey Zinc Co. and the United States Gypsum Co. and has for a great number of years been closely connected with the metallic industries. Associated with Mr. Columbia are Virgil G. Marani, former Building Commissioner of Cleveland; Victor Hugo Halperin, formerly advertising manager of the General Fireproofing Co.; F. W. Leggett, director of publicity of the Bell Telephone Co.

Manufacturers' Catalogs

THE AMERICAN STAVE & COOPERAGE CO., Chelsea, Mass., is distributing a booklet on its tanks, profusely illustrated.

THE METALLURGICAL RESEARCH ENGINEERING CO., Chicago, Ill., is issuing a series of useful charts giving in tabular form results of a number of physical tests on the steels of various analyses and heat treatments.

THE LINK-BELT CO., Chicago, Ill., has just issued two new catalogs. Book No. 375, entitled "Link-Belt Labor-Saving Elevators and Conveyors," illustrates and describes in 108 pages the many different types and the purposes to which they can be used. Book No. 380 is on electric hoists and overhead cranes, which covers in 100 pages electric hoists, monorail trackwork for electric hoists, electric telphers, overhead traveling cranes and revolving locomotive cranes, which are illustrated and described.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., is issuing a new small folder describing C-H Electric Space Heaters known as Pub. 494. One of the illustrations shows the space heater with a 2-ft. rule held alongside to illustrate further the fact that this heater is 2 ft. long. It is referred to in the folder as "Two Feet of Electrical Heat." A large broadside has also been printed, reproducing many of the current advertisements on this space heater and including in it a list of publications in which the advertisements are appearing, together with the dates. This company has also issued two booklets: Booklet A, on "Motor-Operated Brakes for Alternating Current Service," and Booklet S, on "C-H Magnetic Separators."

THE WALTER A. ZELNICKER SUPPLY CO., St. Louis, Mo., is distributing a folder (No. 275) giving a list of the special offerings of rails, cars, locomotives, steam shovels, generator sets, air compressors, engines, boilers, hoisting engines, pipe, steel piling, tanks, etc.

THE NORTON CO., Worcester, Mass., has just issued nine booklets as follows: Health Bulletin; Storage, Handling and Supervision of Grinding Wheels; Safety as Applied to Grinding Wheels; Alundum Tile and Terrazzo Aggregates; Test of Alundum Tile at Columbia University; Safety Code for the Use, Care and Protection of Abrasive Wheels; Indiana Hill an Industrial Village, by Clifford S. Anderson; Principles of Cylindrical Grinding and Norton Service.

HOLZ & CO., INC., New York City, is distributing Bull. No. 22-23, on the Holz Universal Photo-Micrographic and Macrographic Metallographic Bench Model 1920, for magnifications from 1 to 3,500 diameters, with apparatus for "selective" vertical illumination and other important improvements.

W. S. ROCKWELL CO., New York, has issued Bull. 200, which illustrates and describes in detail a new and novel type of furnace—side-opening heat-treatment furnace. It was developed to heat treat material varying widely in shape and size. This furnace is 36 ft. wide. Stock approximately this length may be placed in the furnace for heat treatment, or the furnace may be partitioned off into individual chambers 5 ft. 9 in. wide or multiples thereof. Thus, while one chamber was heating stock say 5 ft. long, the other part of the furnace could be heating stock either much longer than 5 ft. or smaller. This furnace is now being widened to provide a working chamber 105 ft. wide in the clear, the length remaining the same. This increased width will provide facilities to anneal and heat treat the largest shafts and similar pieces handled in this forge shop. The doors of the furnace can be raised or lowered independently of one another. They are operated by compressed air and counterweights. They are dovetailed and form guides within themselves that prevent the escape of hot gases. The roof of the furnace is constructed of flat tiles, avoiding the thrust caused by the ordinary arch construction. The furnace is underfired, assuring a uniform heat treatment. It is provided with preheaters over the vents. The air in these preheaters thus returns through the burners the greater portion of the heat in the spent gases that would otherwise be lost. The fuel consumption in this furnace is extremely low, due to the efficient application of the heat and the utilization of the waste heat ordinarily lost. Oil or gas may be used as fuel. Expansion of the brickwork, or of the furnace as a whole, is taken up by the heavy springs at the side of the furnace.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

Mr. Lane Points the Way

IN HIS letter of resignation as Secretary of the Interior the Hon. FRANKLIN K. LANE wrote to the President as follows:

"In parting, let me say a general word as the fruit of my experience here. Washington is a combination of political caucus, drawing room and civil service bureaus. It contains statesmen who are politicians and politicians who are not statesmen. It is rich in brain and in character. It is honest beyond any commercial standard. . . . But it is poorly organized for the task that belongs to it. . . . Ability is not lacking, but it is pressed to the point of paralysis because of an infinitude of details and an unwillingness on the part of the great body of public servants to take responsibility. . . . We have so many checks and brakes upon our work that our progress does not keep pace with the nation's requirements. We could save money for the Government if we had more discretion as to how we should use that given us. . . . As matters are now devised there are too few in the Government whose business it is to plan. Every man is held to details, to the narrower view, which comes too often to be the department view or some sort of parochial view. We need for the day that is here and upon us . . . more opportunity for planning, engineering, statesmanship above, and more fixed authority and responsibility below."

These are words of wisdom. In somewhat the same line of thought the Hon. FRANK O. LOWDEN, Governor of Illinois, said at a meeting in Brooklyn the other day that while industry has advanced within the last century to meet new conditions, the art of government had stood still. In some respects it had gone backward. We have bureaus and commissions by the hundred, and these overlap in function, but lack correlation. We have no department of public health, and yet there are about forty-two bureaus in Washington that relate to it. On taking office in Illinois he found a great number of commissions, and commissions are usually given to discussion rather than to action. In co-operation with the Legislature they succeeded in superseding the commissions with nine departments of government—and no more—with one man at the head of each, and he is made responsible for its conduct. The head of the Department of Finance has no other obligation, but he can withhold disbursements even of money appropriated if he does not believe the expenditure is proper. The appeal over such a decision is to the Governor. In the United States Government all departments are spending departments. Even the Secretary of the Treasury is loaded with administrative details—such as the United States Coast Guard, Public Buildings, etc.—and appropriations for all departments may be spent in full without check. Unless our wasteful methods are reorganized, taxation will constantly grow, and with the present burden, if we run into bad times, it will take us a very long time to overcome them; because no one will venture expenditures for new enterprises with the increased hazard of loss and the certainty of taxation if profits ensue.

This sounds right to us also. The fact is for nearly 150 years we have been run by politics in affairs of government, and politics have failed. We are growing impatient under the inefficiency of political administration. We are sick and tired of politics, although we must have them, just as we must have boots and shoes. But just as we do not want to restrict our lives and thoughts to boots and shoes, so we do not want our government to consist of politics and nothing else. The inefficiency of both Republican and Democratic Congresses of the United States for many years past is a thing to be ashamed of. We have not the patience to listen to the men who "point with pride" to the achievements of any of them. We want to hear of opinions and plans without any fireworks. That letter of HERBERT C. HOOVER to his friends probably did not please the politicians. They were not used to it. They want points to yell over, and this was modest but earnest. To us it appealed as the very attitude of mind which we long for in our representatives in government.

Practicing Industrial Good-Fellowship

THERE is more merit than fault (until the habit becomes a nuisance) in the man who stands up for his home town and district. The trouble is that in our patriotic boasting we may confine ourselves to the talking points that we have learned, and mere recitations often lose weight and even interest in discussions among the thoughtful. Thus a vapid, fat, lazy, inert man of the East, who cannot see the difference between an inch and a centimeter, is likely to make the observation with half-closed eyes, between the puffs of his cigar, that a man from the West is unable to perceive the fine distinctions which are clear to his brother of the East. And a similarly undesirable person from the West sometimes offends with the assertion that because a man is from the East he must perforce lack vision and understanding. Such persons give us a pain in the mind.

On the other hand we may observe traditions and habits that have developed in various parts of the country which are, in a way, sectional and it is to a certain conflict of habit in industry between the East and the West that we now desire to call attention.

When the late Dr. JAMES DOUGLAS undertook to engage in smelting copper, he was modest enough to be-

lieve that he did not know everything there was to be known on the subject. He caught, let us say, the air of the great plains and the big hills, and he thought large. He felt that no matter what his part in it might be, the American copper industry was a thing in itself, and the more it prospered the better it would be for all concerned. He was scrupulous in the defense of the interests for which he was responsible, but as an artist in smelting copper he wanted to learn as much as he could, and he was enough of a psychologist to know that the way to learn is to tell. So he kept open house for metallurgical engineers and, since turn about is fair play, others made him welcome also.

The Western copper mining and smelting industry grew by leaps and bounds, and its traditions of hospitality remain to this day. Occasionally an engineer or metallurgist of one of the great establishments in Montana or Arizona goes on a vacation for a month or so, and instead of coming to New York to analyze Broadway it is probable that he will go where competitive operations are in progress and visit his brother engineer or metallurgist. Everything is open to him. He finds some new wrinkles that he resolves to adopt, and he tells his friend how he or his staff has conquered difficulties that still loom large in the eyes of his host. The patentable ideas in industrial improvement are far fewer than those that are not patentable, and as a result of this friendly visit the stockholders of both concerns may profit. There is no tragedy in the accretion of profits by competitors.

We have not reached the last word in metallurgy, by any means, but just because of this open-mindedness and give-and-take quality of Western engineers they have ventured to build much larger units and they have succeeded in producing metals with far greater economy than if everyone had worked in secret and been limited by his own imagination and technical experience. It is fair to say that industrial good-fellowship has contributed largely to the American copper industry.

This tradition is less developed in the East in chemical industry. We have in mind two engineers who came from the West and were engaged as respective managers of competitive works making a standard product. They had worked together in a friendly way in the West and were familiar with the tradition of industrial good-fellowship. One of them was even imbued with the belief that this tradition might find a welcome in the East. He had trouble with a certain step in a process and was about to post off to his friend to confer with him about this and other methods of procedure. He planned, as usual, to match his experience with that of his friend and to see how conditions and quality and yields might be improved. He had some ideas that he hoped to try out, but he wanted first to talk them over with someone competent by education and experience to advise with him. The directors got wind of his intention and they proceeded to throw fits. Their manager was about to confer with their greatest competitor and thought to give away all their secrets! (The competitive corporation in the meantime was doing very well, thank you, with *its* secrets.) Such a breach of sound business methods had never been heard of by the board, and the manager was informed, with such charity and patience as should be employed with innocent offenders, that he must not go. He had better not, they said in their abundant caution, even associate with his friend. If he could get the information desired without giving anything in return, that would be desirable, but he must bear in mind that the hazard of letting information as to their establishment slip out was to be avoided. On the other hand, if he could manage to lure away some employees that worked under his friend, this would find favor with them, and they were even prepared to make a special appropriation to accomplish it.

Here they struck a snag. The poor fellow suffered from inhibitions. He had grown up to believe that it was contrary to professional ethics to hire away employees from other works, and he would not even try to do so.

He is a chastened man, and the directors continue to direct—which is as it should be. Directors should direct or get out and give way to men who know enough to do so. But as we have intimated before, one of the greatest needs of chemical industry in America is resignations or obituary resolutions among the boards of directors of a considerable number of establishments.

Technicalities
Concerning Alcohol

ALCOHOL has long been distinguished by marked legislative attention, having been revenued and licensed for years and years and finally regulated to such a degree that only those proficient in law could make out exactly what rights still belonged to it. Even in regard to these, our most noted lawyers find scores of technicalities of a pro and con variety. As an illustration, take the brief of the law firm of ELIHU ROOT endeavoring to persuade the Supreme Court that the Eighteenth Amendment to the Constitution, which made national prohibition possible, was not legally adopted and is therefore invalid. Mr. ROOT contends that this method of legislation is novel, not supported by precedent and is distinctly opposed to proper procedure. Also the amendment "directly and substantially" tends toward the "destruction of the right of the several states to local self-government" and interferes with the taxing and police powers of the state.

It is a humorous incident that Congress in proposing the amendment left out the usual preamble advising the states that two-thirds of both houses of Congress deem the amendment necessary, which, by the way, ought to set an excellent example to those concerned with the enforcement of the law. Also the length of red tape to which users of industrial alcohol must submit ought to be beneficially influenced by this practical precedent in Congress. It is at least hoped that the preambles and other extravagant time-consuming non-essentials will not continue to play a predominant part in matters pertaining to industrial alcohol regulations.

New regulations for the alcohol industry have recently been enacted and a concise interpretation will be found on another page in this issue. A careful study is recommended to those who are in any way concerned with industrial alcohol, not only for their present guidance but to determine what changes can be made in future regulations to lighten the burden on the users of it in industry without impairing the effectiveness of the prohibition law. The Government is clearly on record as being desirous of promoting legitimate uses of alcohol. It remains for industry to co-operate with the Government in order to determine and put into effect regulations which will be satisfactory to all concerned.

Users should bear in mind that at present only four denatured alcohol mixtures are free from both governmental regulations and taxes and may be sold, distributed and used without any restrictions. The ten-part-wood-alcohol mixture has been withdrawn because of the great number of deaths caused by its use as a beverage. The courts have decided to hold for trial all parties found responsible in wood alcohol poisoning cases, and heavy sentences have been imposed on all those convicted. Nevertheless other denaturants, such as certain petroleum distillates, pyridine, nitrobenzol, sulphuric ether, etc., are more than filling the gap made by removing the ten-part-wood-alcohol product from the open market. It is hoped, however, that better formulas will be developed that will give the public a less obnoxious denatured alcohol, at once fool-proof and nonpotable.

While all authorized denatured alcohols are tax free, pure ethyl alcohol is allowed to go tax free only under bond and regulations, and only to those who make scientific application of it. Special care must be taken to prevent thefts and resultant misapplications, the occurrence of which results in the $4.18 tax being collected from the bond. There is no more ingenious burglar than the alcohol thief. He has been known to bore through the floor of a car or room right into steel drums, if necessary, to secure his prize. Desire is the mother of ingenuity.

The Steel Industry Can Function

FEARS entertained, or at least expressed, last December, that the iron and steel industry would not be able to function well this year, or at least during the early months, are now largely dispelled. The change in viewpoint is partly psychological, and therefore carries a favorable augury for other industrial activities of men. During the war the feeling was, "It can be done," but after the war there seemed to come a feeling, "It can't be done." There was always something claimed to be in the way. Since the steel industry was formerly noted for its sanguine temperament, its more courageous viewpoint at this time may be expected to be followed by a better feeling all around in industry.

The steel industry was afraid it would not have enough labor, or that if it had labor the men would not know how to work or would not be willing to work, and fears were also expressed that there would not be enough transportation, particularly for coal and coke. In January there was little complaint of labor shortage and not much of labor inefficiency, yet throughout the month there was much complaint of car shortages, affecting the movement of beehive coke, of coal for byproduct ovens and steel plants and of intermediate and finished products. Yet when records were compiled it was found that pig-iron production in January was 14 or 15 per cent greater than in December, and steel ingot production was 83 per cent of capacity, taking capacity at 49,000,000 tons a year. In December some mills had predicted that they would not be able to average more than about 75 per cent production during the first quarter of the new year, this being based on assumptions of a lower rate than that in January and of a higher rate in March.

The actual test of operation has furnished some other surprises, or divergences from prognostications. During the war there was heavy new construction of open-hearth steel furnaces, whereby a common estimate was that steel ingot capacity was increased by 40 per cent during the war, from about 35,000,000 tons a year at the beginning of 1915 to about 49,000,000 tons in 1919. Then it was asserted that steel-rolling capacity had not been increased correspondingly, hence at the close of the war, with the manufacture of shell steel, involving little rolling, discontinued, the steel industry would find itself capable of making more steel, in ingot form, than it could finish. Unfinished steel would therefore be found relatively plentiful and finished steel relatively scarce.

Nothing of the sort has developed. Ingots have not been offered in the market at all. Blooms and billets have been scarce and have brought very high prices relative to the average prices at which finished steel has been delivered. The circumstance is the more remarkable from the fact that the demand for finished steel as a whole has not followed the usual analysis or distribution among the various finished products. With such conditions, unfinished steel should be abnormally plentiful, through some finishing departments being unable to supply the demands upon them and other finishing departments having an especially light demand for their particular forms of product.

Another prediction made before the close of the war was that sheet rolling capacity would be found insufficient to the demand, because so few sheet mills had been built during the war. In the last analysis such a condition might be proved, theoretically, to exist at present, but the actual experience in the trade in the past few weeks has been of sheet consumers bidding up prices of sheet bars, purchasing any lots they could secure, and experiencing no difficulty in finding sheet mills with reserve capacity, ready and anxious to make conversion contracts to turn consumers' sheet bars into sheets for them. The fancy prices have been paid not for the conversion of the bars into sheets, but for the sheet bars themselves.

Again, there was argument as to the supply of basic pig iron. It was maintained in some quarters that there had been so much new construction of basic open-hearth furnaces that basic pig iron would be made extremely scarce, while one rejoinder was that the scarcity might not occur, because the steel mills would experience a greater scarcity of labor than the blast furnaces, whereby the steel mills would not be able to consume pig iron in proportion to their physical capacity. Pig iron did become scarce, it is true, and prices advanced rapidly, but the advance was led by foundry iron, not basic, the basic grade for a long time trailing far behind foundry iron in the matter of price.

These and other observations that could be made all make the same showing—that the steel industry really can function, and function well. It can operate in circumstances that were claimed would present insuperable obstacles. The industry should now take on fresh courage, forget theoretical obstacles, and bend all its energies toward building up markets, rendering service to consumers, producing its material at the lowest possible cost and encouraging consumption by selling its output at the lowest margin consistent with a fair return upon the capital and effort involved in production.

Readers' Views and Comments

Mr. Hoover and the Presidency

To the Editor of Chemical & Metallurgical Engineering

SIR:—In view of the notes you have published recently regarding Mr. Hoover and the Presidency you may be interested in giving your readers an opportunity to get a little deeper insight into the man and his history. The accompanying quotation is reported to be from a letter written by Mr. Hoover to Casper W. Hodgson, a Stanford classmate, and is taken from a recent issue of the New York *World*.

It discloses the saving grace of humor so essential to the peace of mind of those who become popular subjects of conversation.

> I have noted your feeling that I should answer some of the solemn discourses on my private life and crimes. I do seem to get into the way of politically minded folks even when trying to keep out of politics.
>
> Some things that have been said of me cause me a sense of financial oversight. For instance, I have made quite careful inquiries and I regret that so far I cannot find—
>
> (a) The $10,000,000 I am said to have made in my early youth, or even middle age, or altogether, or any respectable part of it.
>
> (b) The investments that I am supposed to have in Great Britain.
>
> Like the negro porter who was asked to change $10, I am grateful for the compliment. I am sorry that these sums do not exist, for they would be useful for Children's Relief.
>
> I have also given deep consideration to the other items mentioned:
>
> (a) Am I a British subject? Did I ever apply for such citizenship? No. Many generations of persecuted Quaker ancestors would rise in their graves at such a discovery. They should remain quiet, however, for no Californian could live three months in London climate and become a British citizen if he knew it. One thing that reassures me that this did not happen without my knowledge is that the British refused to allow me to come into their island during the war without an American passport. Also, I feel that my accent was disinfected of any English, French, Chinese, Russian or other taints by my presence in the United States a portion of every calendar year of my life except three—even including the five in which the United States has exercised its right to draft my services, a good portion abroad.
>
> (b) Did I ever rent a "residence" abroad? I plead guilty of this crime, but in mitigation I do appeal to the feelings of fathers who object to hotel life for babies and children.
>
> (c) What about the political lunch where I was supposed to have entered upon a dreadful conspiracy against the weal of the American people? My real distress in this matter is not to prove an alibi, or even to complain that my name was not even mentioned, as the guests assert, but it is that I was not even invited and therefore lost an excellent lunch.
>
> (d) I plead guilty to the criminal charge of pursuing my engineering profession in foreign parts again and again. I have a fervent hope, however, that this new doctrine of criminality will not deter our citizens from extending American professions and business anywhere in the world. They always bring something home and pay taxes on it.
>
> (e) I gather also that it is moral turpitude on my part to have managed large enterprises. The hope to rise from the ranks of labor to the ranks of management will, however, probably not be crushed from the hearts of the American boy even by this onslaught.

Whether Mr. Hoover is ever elected President or not, the politicians will at least have become acquainted with a man who is independent, incisive and direct.

ENGINEER.

Chemistry for Undertakers

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the December, 1919, number of the *American Funeral Director* there is a contribution by Prof. C. A. Moadinger on "Chemical Conditions of the Body and Fluids" which is so full of new ideas that I could not forbear to make a transcript of some of them for the benefit of my fellow-readers. In a boxed note on the text, it is stated that the professor comes from Brooklyn, which is confirmed by the telephone directory. From the same source it appears also that he is an undertaker. In regard to the chemistry of human bodies both in life and in death he states that only lately has he been able to resume his work, that in this he has addressed himself more particularly to elementary features, and that he has "gotten" it down to a state that he believes will be understood by his audience.

"The first chemical condition of the body" that he studied was the organic salts which go to make it up, and these organic salts, he tells us, are phosphates of lime and carbonate of lime. Next to water, phosphate of lime is said to be the principal ingredient of the body, while of the carbonate there is only one-seventh as much. If we have an excess of lime in the blood, there occurs a lime deposit on the inner and middle coats of the arteries; then we have arteriosclerosis.

If into a body which contains an excess of lime, embalming fluid is injected, why is it that the fluid does not seem to be assimilated, and why does the body remain soft? The professor puts the question and answers it, as follows: "You had an excess of lime in the blood. The excess of lime, by the action of the formaldehyde that you injected, caused the carbonate of lime, which is flakes. If you take a phosphate of lime solution, or lime-water, and put a little formaldehyde into it and hold it up, you will see it flaky all through. The carbon from the formaldehyde combining with the lime forms carbonate of lime, which is flakes, and these get into the little blood-vessels and capillaries and plug them so that no fluid is allowed to pass through. That is the condition you have with excessive lime in the blood." Evidently, flakes cause undertakers as much trouble as they do steel makers!

In cases of hardened arteries the professor notes that frequently the injections of embalming fluid seem ineffective; that the injection is "hard" and the bodies are not so rigid as they might be. "This," he says, "is due to the fact that your osmotic action was lost, the lime forming a coat on the inner walls and preventing the passage of the formaldehyde and other chemicals through the blood-vessels through the tissue. You know osmosis is the passage of one liquid through a membrane into another liquid."

Other difficulties in embalming he also attributes "to the action of the formaldehyde upon the lime, which forms a carbonate of lime."

"Another chemical in the body," he says, "is known as magnesium, and is found in the muscles and the brain, but more predominant in the muscles than in the brain—here we have again by the action of formaldehyde on this magnesium a carbonate of mag-

nesium formed, which is insoluble and forms flakes." Chloride of sodium he declares to be the most important chemical found in the body, and he says it is contained in all the parts; in blood, bones, brain, hair, and in every tissue of the body. He explains its ubiquity as follows:

> We must have salt, first as an alkaline in the blood to keep it in the alkaline condition; to keep it from coagulating so that it will give us a clear, perfect flow. Sometimes you crave something salty—which shows your system is in need of sodium chlorine to carry on the work of lubricating the blood—sodium chloride acted upon by formaldehyde produces no other chemical. But sodium chloride aids osmosis, and if it were used more in embalming fluids, you would get better osmosis. Common salt injected into the body aids in preventing the formation of carbonate of lime from phosphate of lime.
>
> We have a sodium potassium and potassium phosphate in the body, and these are found mostly in the kidneys—some are alkaline and some are acid. The action of formaldehyde on sodium phosphate and potassium phosphate has no bad effect outside the body.
>
> The sodium and potassium carbonates are entirely different because they contain a certain amount of carbon which is found in the body, and the action of formaldehyde on carbonates increases rather than destroys them, and we get a higher degree of carbonization so that we have a precipitate thrown down from the sodium and potassium carbonates.
>
> The sodium and potassium sulphates are in very small amounts in the body, and play but little part. If anything they aid considerably to cosmetic effects, and that is all.
>
> The formation of uric acid from eating fresh beef forms in the kidneys in the form of crystals which are insoluble. These crystals break down—decompose, as it were—to form carbonate of ammonia, which forms in the kidneys and gets in the urine. This penetrates the system and gives the peculiar odor to bodies dying from Bright's disease. In these cases the action of formaldehyde is entirely lost—it is changed into an entirely different composed part; the ammonia takes up more of the carbon from the formaldehyde, changes it back into an acid similar to formic acid, and the action is lost as far as disinfectant, astringent and preserving properties are concerned.

It is rare indeed that so many novel observations in chemistry are recorded in a single paper. Prof. Moadinger contributes two new organic salts in sodium phosphate and sodium carbonate. The reaction of formaldehyde in "forming" carbonates is worthy of note. A new definition of osmosis is contributed. We learn of the "predominance" of magnesium in human muscles, of the lubrication of blood by sodium chlorine, and of common salt as an "aid" to osmosis. The point as to the alternating acid and alkaline reactions of "sodium potassium and potassium phosphate" seems well taken, especially in regard to the kidneys, while an entirely unexpected function of formaldehyde in increasing "carbonization" is recommended to the attention of all persons engaged in work on synthetic resins. Entirely new is the action of sodium and potassium sulphates as aids to "cosmetic effects." It suggests additional research as to the cosmetic effect of lithium sulphate and opens up the entirely new field of *cosmesis*, whatever that may be. New to the writer also is the dissociation of uric acid to ammonium carbonate, and the third note on the behavior of formaldehyde, this time in the presence of ammonia.

Not infrequently, Mr. Editor, you have urged in your editorial columns the spread of chemical understanding among the people. I offer these selections from Prof. Moadinger's address before the Missouri Funeral Directors' Association as the very flower of popular chemistry.

MARTIN SEYT.

New York, N. Y.

American-Scandinavian Foundation Fellowships

THE traveling fellowships established by the American-Scandinavian Foundation of New York City promise to rival the Rhodes scholarship plan in interest aroused among American colleges. Twenty fellowships, each with a stipend of at least $1,000, and in some cases $1,200, will be awarded in May to American students, men and women, for technological research and humanistic study in the Universities of Sweden, Denmark and Norway. When it was announced a year ago that young American engineers and students of science would be given opportunity to study under such eminent scientists as Svante Arrhenius, founder of the theory of electrolytic dissociation, or Hjalmar Lundbohm, director of operations on the great iron mountains at Kiruna, officials of American technological institutions recommended for consideration the names of promising recent graduates. The men who were appointed, and who are now in Sweden, represent the best known scientific schools from Massachusetts to Wyoming. It is required that all candidates be of American birth, and all of these men had rendered scientific or military service in the army of the United States.

Scope of Fellowship Plan Extended

Since that time, the scope of the fellowship plan has been greatly extended. The number of fellowships has been doubled so that five students will be sent to Denmark and five to Norway in addition to the ten to be appointed for Sweden. Not only will fellows be appointed for the study of chemistry and physics, hydro-electrical engineering, metallurgy and forestry—in all of which subjects Scandinavian countries excel—but also for agricultural sciences and for language and literature. Denmark's agricultural system and her system of folk high schools have attracted to Denmark many an educational commission from foreign countries; and English literature has drawn freely from the North from the time of the sagas of Beowulf to that of the tales of Hans Andersen. Fellows will also be appointed to Norway for the study of oceanography, the new science of the sea fathered by Fridtjof Nansen and Helland-Hansen; and for the study of weather forecasting under Prof. Bjerknes of the Bergen Geo-Physical Institute.

These twenty fellowships for American students are one-half of a group of forty exchange fellowships between America and the Scandinavian countries financed on the one side by twenty American individuals and corporations, and on the other side by twenty Scandinavians. In other words, ten students will come here from Sweden, five from Norway and five from Denmark.

How to File Applications

Application papers with letters of recommendation must be filed at the office of the American-Scandinavian Foundation, 25 West 45th St., New York, before April 1. The selection of fellows will be made by a jury of university professors and technical experts appointed by the Foundation.

Successful candidates will be notified about May 1 and are expected to sail from New York in early summer, so that they may have several weeks before the opening of the universities, to travel about in the countries to which they are appointed, familiarizing themselves with the language and life of the people.

Award of the Nichols Medal to Dr. Langmuir

THE Nichols Medal of the American Chemical Society was awarded for the second time to Dr. Irving Langmuir of Schenectady on Friday evening, Feb. 5, at Rumford Hall of the Chemists' Club, New York. Despite snow, sleet, rain and wind, it was a capacity audience, and its enthusiasm was as great as though some new and gifted star had arisen in the opera firmament.

Prof. Ralph H. McKee of Columbia presided, and Dr. William H. Nichols, past president of the Society, made the presentation.

Dr. Nichols gave a brief sketch of Dr. Langmuir's life and work, and with no regret that he had given up teaching and devoted himself more abundantly to research with the splendid opportunities and facilities at hand in Schenectady, he could not resist the thought what an inspiration he would have been to the coming generation of chemists if he had continued to teach. Dr. Nichols intimated that plans were in the making to improve materially the situation of professors of chemistry at universities and technical schools. Details may not be divulged as yet, but he hoped they would be in initial operation within the coming year. In awarding the medal he expressed the general approval of the recipient's fellow chemists, not only of the originality and vast scope of his work, but also of his constant disposition to accord credit to all those whose contributions had illuminated him and who had aided him in his research.

DR. IRVING LANGMUIR

In accepting the medal Dr. Langmuir said that his curiosity in regard to the structure of atoms and molecules had begun when he was studying physical chemistry with Professor Nernst at Göttingen. Research in reaction velocities fixed in his mind the idea that there must be reasons for the phenomena exhibited, and that it was our business to find them out. Atoms and molecules had seemed real things to him rather than vague and shadowy concepts. His subsequent work confirmed this curiosity.

About a year ago he had been asked to deliver an address on adsorption at a colloquium of the staff of the research laboratory of the General Electric Co. at Schenectady. He felt that such a lecture would be but a review of the work already done and already available. On the other hand, in regard to the structure of atoms and molecules there was a field in which thought should be encouraged. The researches of physicists indicated atomic structures as built up of electrons revolving in circular or elliptical orbits around a nucleus. But if chemical reactions depend upon atoms and molecules, these must have some definite structure; they must have individuality; and there is not much individuality in concentric circular orbits all in one plane.

In a short section relating to the Cubical Atom in a paper on "The Atom and the Molecule" by Prof. G. N. Lewis of California, and published in the *Journal of the American Chemical Society* in 1916, he believed that enlightenment might be found. This, he said, had been his real starting point, and his work followed that of Prof. Lewis, who had, however, considered only the simpler elements. The speaker thought the theory might apply to all elements, and subsequent research has confirmed him in the belief. So leading, indeed, was this little four- or five-page note on the Cubical Atom in its suggestion that he ventured the opinion that Dr. Lewis was at least as fully entitled as himself to receive the medal. During the war, while engaged on submarine problems, he met many foreign men of science of the first rank and was surprised to observe that Lewis's contribution seemed to be wholly unknown to them.

We can, he said, count the atoms in a gram molecule more easily than we can take the census of a city. Atomic and sub-atomic magnitudes are as available to us as those of astronomy, but we are less accustomed to consider them. A few examples may help. Thus if a lump of matter the size of a baseball were magnified to that of the earth, the atoms would be the size of a baseball. If the molecules of a cubic inch of air were changed to grains of sand small enough to pass through a 100-mesh sieve, the sand would fill a trench 3 ft. deep and a mile wide from New York to San Francisco. Recent work has shown that atoms consist primarily of a nucleus. Here all the positive charges are concentrated. The number of positive charges in the nucleus of an atom is the same as the atomic number of its element in the periodic scale. Thus hydrogen is No. 1, helium No. 2, lithium No. 3, etc., right up to uranium which is No. 92, and the nuclei of the atoms of different elements differ from one another in the number of their positive charges in this respect. Arranged around each nucleus are electrons in the same number as its positive charges. All electrons are alike. The nucleus of an atom is very small and its diameter is not more than one hundred-thousandth of that of the atom itself. If we were to magnify an atom to the diameter of one mile, then the electrons would be about 5 ft., while the nucleus would be about the size of a walnut.

Bohr's theory of rotating electrons has found favor among physicists, but it does not satisfy the chemist. It does not explain the simplest facts. It does not explain, for instance, why lithium is not an inert gas. Lewis could not accept Bohr's theory, and he made electrons stationary, but this concept is not necessary. All that Dr. Langmuir claims is that whatever the rotation or movement of an electron in an atom may be, it is not in an orbit around the nucleus except perhaps in the cases of hydrogen and helium, but rather within a circumscribed space in relation to the nucleus. An electron in an atom has, to borrow a biological term, its restricted *habitat*, and within this habitat there is no objection to its rotation or movement. This provides three-dimensional space for the electron instead of holding it to rotate in a single plane of two dimensions. The key to the octet theory is the inert gases. These are stable, do not form molecules, and apparently have a

structure in which an approximate balance of forces obtains. Low boiling points indicate this, for the obvious reason that the field of force surrounding the atoms must be very slight. If we should consider consciousness as a function of inert things, it would appear that these erstwhile pariah elements represent an ideal of matter. All chemical energy, change and reaction would appear as due to an effort to achieve their constitution. They represent a form of arrangement toward which electrons of the outer shells of other atoms seem driven to compose themselves. Abundant reasons were given to explain why, as the associations of positive and negative charges of these inert elements grow in complexity with increasing atomic weights, the number of other elements which may conform to their structure also increases. We shall give but a slight outline of some of the features presented, and refer to Dr. Langmuir's several contributions to the *Journal of the American Chemical Society*, of which the first appeared in June, 1919, and to an article on the Langmuir Postulates by Ellwood Hendrick in our issue of July 15, 1919.

Outline of the Langmuir Postulates

The hydrogen atom has one positive charge at the nucleus and one electron. Helium has two positive charges and one electron in either hemisphere surrounding the nucleus. That of the atom of every other element has positive charges corresponding to the atomic number and, as in the helium atom, a pair of electrons, as with helium, surrounding it. Additional electrons to make up the number of the positive charges are arranged within concentric spheres outside this kernel (consisting of the nucleus and two electrons) so as to indicate a cube. In other words, if we were to divide two concentric spheres surrounding the kernel into eight parts we should find within the eight spaces between the spheres the "habitat" of each electron, and this is called its cell. It does not leave this cell unless its place is on the outside of an atom. The average position of electrons in each shell or pair of concentric spheres is at one of the eight corners of a cube. The chemical activity is chiefly on the outside of atoms, and among the inert gases all eight places in the outer shell are occupied by electrons, which explains the internal balance of forces and the chemical inertia of their atoms. No other element has this arrangement, and when the octet-forming drive of the seven outside electrons of an atom of fluorine, for instance, draws from an atom of sodium its single outside electron so that the arrangement of electrons of both is similar to that of a neon atom, then the fluorine atom becomes a fluorine ion, because it is negatively charged, while the sodium atom becomes a positively-charged sodium ion. (The atomic numbers are F, 9; Ne, 10; and Na, 11). Electrostatic force will hold the two ions together. Such combinations of ions do not form molecules, but join in a lattice, as described by Bragg. Molecules are formed as set forth in the papers referred to by the sharing between atoms of pairs of electrons in common.

The concept of the cubical atom is one of convenience rather than of precision, as is the benzene ring. Atoms of the inert gases are probably in fact approximately cubical in the arrangement of their electrons, but in a molecule consisting of atoms and ions having different concentration of charges at their nuclei, it stands to reason that the cubical forms are subject to considerable distortion.

A pleasing incident was a number of models of atoms and molecules prepared by Leffert Lefferts, which were displayed with gusto by Dr. Langmuir. That of acetic acid, which looked something like the framework of a toy airplane, was immediately recognized by the speaker for what it was designed to be, as indeed were all the other models as well.

Given adequate familiarity with the Langmuir Postulates along with the proper scholarship in science, a chemist should be able to visualize definitely the structure and form of atoms and molecules, and to consider the play of forces within and without them. He should even be able to predict within approximate limitations the physical qualities of a substance before it is synthesized. He should be able to foretell the gas, liquid or solid phase at ordinary temperatures, its electrical conductivity, crystal forms, color, etc.

When Dr. Langmuir presented his first paper on the subject at the Buffalo meeting of the American Chemical Society, Professor Washburn of Illinois offered the opinion that the occasion was momentous, and that we had listened to the greatest contribution to chemistry since John Dalton presented the atomic theory. We have not heard that he has changed his opinion.

British Production of Alcohol From Coal

The extraction of alcohol from coke-oven gas on a commercial scale was proved to be possible at a meeting of the Cleveland Institute of Engineers at Middlesbrough (England) by Ernest Bury, of Skinningrove Iron & Steel Works. Mr. Bury showed that he had succeeded in extracting ethyl alcohol and its derivatives. The practical working of Mr. Bury's process at the Skinningrove plant, where 5,800 tons of coal are carbonized per week, revealed an average yield of 1.6 gal. of alcohol per ton of coal carbonized. The ethylene in the gas is absorbed in sulphuric acid, forming ethyl sulphuric acid, which is hydrolyzed to ethyl alcohol.

The total weight of coal reduced to coke in the United Kingdom in 1918 having been 14,635,000 tons, the application of Mr. Bury's process to the entire amount of coal would yield 23,416,000 gal., the value of which would be £2,341,600 ($11,395,000). The recovery of alcohol at the gas works of the country would yield a further 27,000,000 gal., or alcohol and benzol, taken together, would amount to 114,000,000 gal., to meet the requirements of the country, which amount to 160,000,000 gal. per annum.

Condition of the Belgian Plate and Window Glass Industry

The revival of the Belgian plate and window glass industry continues in spite of the shortage of industrial fuel and certain raw materials, notably sodium sulphate, and the transportation difficulties.

The average increase in labor costs since the armistice has been 150 per cent, taking into consideration the shortening of the hours with the general introduction of the 8-hr. day. A general increase of 10 per cent was recently granted, and operatives are now claiming further advances of from 10 to 20 per cent.

At present all of the eighteen window glass plants in operation before the war are again producing; in nearly all of them, however, only one furnace is lighted, and others cannot be started until regular fuel supplies are forthcoming.

Government Chemists' Salaries

Although chemists are classified separately, as are all of the other technical groups, they receive the same salary recommendations from the Commission on Reclassification of Government Salaries which reported to Congress on March 12. The Commission has not recommended as great increases as were recommended to it by the chemical advisers from the employees themselves, but the increases, if they are approved and accepted by Congress as the basis for action, will be sufficient to reduce materially the difficulty of holding the right sort of men.

To carry out the work started it is recommended that the Civil Service Commission be greatly strengthened and its functions enlarged to include the maintenance of continual classification work and adjustments of wages to meet changing economic conditions. Many other aspects of the working conditions, vacations, retirement, etc., are covered.

Senator Jones of New Mexico, chairman of the joint Congressional Committee on the Reclassification of Salaries, commented on the report as follows:

> Generally speaking, the lower clerical services and lower grades of other services have been remunerated reasonably well. They have received, perhaps, more than is paid for similar service in private employment. In the technical branches of the service, however, the pay has been grossly inadequate. It has not been comparable at all with the salaries paid for the same service in private employment.
>
> Our report will show that there was a crying necessity for this work. The personnel in the Government service is being employed and the work is being conducted without reference to any system. There is little to prompt efficiency and literally nothing to insure a maintenance of effort. To my mind one of the most important features of the report is that part which contemplates increased pay for increased efficiency and decrease in pay when there is decrease in efficiency. If this can be put into practice, I believe it will enable the work of the Government to be carried on more effectively with fewer employees. It will remove injustice and will increase the morale in the Government service.

Production Costs in the Dye Industry

The Tariff Commission has recently issued a pamphlet (Tariff Information Series No. 15) on costs of production in the dye industry during 1918 and 1919. The report is divided into two parts: The first contains a discussion of tables that show in detail the costs of sixteen intermediates and fifteen dyes; the second compares these domestic costs with the prices at which these products sold before the war and at which they are now selling in various markets.

In view of the unstandardized and varying methods of production and of accounting in this industry, the Tariff Commission strongly emphasizes the uncertainty of conclusions drawn from this report and the possibility of error in administrative action based upon such data. The figures are, however, the most trustworthy that can be immediately secured under present conditions in the industry, and in any discussion of the cost of production, the tables given in this report must be accepted as the nearest approach to accuracy now possible.

Tables VI and VII of the report are of particular interest in that they compare American prices on about forty dyes during the period from 1917 to February, 1920, with the German prices f.o.b. warehouse in the United States in 1914 and the reparation commission's prices with the mark valued at par. Table VI gives prices in dollars per lb. while Table VII gives relative prices on the basis of 100 for the German prices of 1914. The accompanying table gives, by way of illustration, the figures for malachite green taken from these two tables.

COMPARATIVE PRICES OF MALACHITE GREEN

	Dollars per Lb.	Relative Prices
German prices, 1914	0.390	100
Tariff Commission report, 1917	6.280	1,610
Tariff Commission report, 1918	5.60	1,435
Market prices, February, 1920	3.50	898
Reparation commission, mark at par	3.2414	831

A marked decrease in the prices of the American products from 1917 on will be noted in the case of nearly all of the dyes listed. It will be noted that for the most part the German prices (reparation commission) are a little higher than domestic prices and that if they were revised with the mark valued at 20c. (the German offer to Dr. Herty), the quotations in the two countries would be surprisingly close together. Furthermore, the reparation prices do not include duties, freight charges, etc., which would have to be paid before the goods could reach the ultimate consumer in the United States. This does not mean necessarily that the American producers can successfully compete in all phases of the dye industry, because in some classes of products, such as vat and alizarine dyes, which are not shown in these tables, but which are of fundamental importance to a well-rounded industry, the foreign producers still have a competitive advantage born of long practice in complicated productive processes. Other complicating factors which make it impossible to draw general conclusions from these price comparisons are conditions of the rates of international exchange.

Pennsylvania Safety Congress

The Pennsylvania Safety Congress for 1920 will be held at Harrisburg, March 21 to 25 inclusive. This Congress is a continuation of the conferences devoted to welfare and efficiency which were held prior to the war, but which have been discontinued since 1917. Arrangements for the Congress are being made by the Department of Labor and Industry, Harrisburg, which will furnish programs and other information upon request. Some topics to be discussed are the cost of industrial accidents, relations between foremen and employees, Americanization, women in industry, rehabilitation of the industrial cripple, occupational diseases and similar subjects.

Tariff Bills Before Senate

Before this issue appears in print it is probable that the Senate Finance Committee will have reported favorably all of the tariff bills which have passed the House and are now pending before the Senate committee. The dyestuffs, laboratory glassware and magnesite bills already are on the calendar and it is probable that similar action will be taken with regard to the measures prescribing duties for tungsten and zinc.

In reporting the laboratory glassware bill, which also carries laboratory porcelain ware, optical glass, scientific and surgical instruments, the committee said:

> Your committee is satisfied from the showing made that we have the skill, the men, and the manufacturers who are willing and able to produce a better quality of articles than can be produced in any other country, and in quantities sufficient to supply all the demands of the United States, if they are properly protected.

Aluminum Rolling-Mill Practice—I Commercial Pig and Scrap

The First of a Series of Articles Discussing the Details of Rolling-Mill Practice for Aluminum, Including All Phases of Work From Pig Metal to Finished Sheet—Metal for Melting Is Considered in This Installment

By ROBERT J. ANDERSON and MARSHALL B. ANDERSON

THE practical details involved in the commercial production of aluminum sheets have not been described hitherto, so far as the writers are aware. A few papers dealing with the working and annealing of aluminum and its light alloys have appeared, to which detailed reference will be made later, but as to the rolling of substantially pure aluminum for the manufacture of sheets, very little, if anything, is on record. With the thought that a detailed discussion of the problems involved in aluminum sheet rolling may be of interest to the non-ferrous industry in general and to aluminum rolling-mill superintendents in particular, the present series of articles is offered. The scope will be mainly confined to the commercial manufacture of practically pure aluminum sheets, but a few notes on the rolling of certain light aluminum alloys will also be included.

General Considerations

Aluminum rolling, for the purpose of manufacturing sheet aluminum, differs from steel, brass and copper rolling in at least one marked essential, viz., the relatively low temperatures employed for hot work; further, all of the final reduction to gage is performed in the cold. Relatively low temperatures are employed for hot rolling, because of the relatively low melting point of the metal, i. e., 658.7 deg. C. In finishing to gage, depending upon conditions, the rolling may be done entirely without annealing between passes, or there may be some annealing done. At the present time, the most suitable rolling and annealing temperatures which should be employed for definite conditions are subjects of considerable conjecture. In fact, considerable doubt is entertained by the writers that many systematic scientific investigations on these matters have been made. However difficult the proof of that statement may be, the fact remains that very little information is available. A good field would appear to be open in aluminum rolling for the application of the methods of physical metallurgy; the use of the microscope in studying the changes brought about on annealing worked aluminum sheet should result in information of real value to those engaged in aluminum rolling. If duralumin is to be rolled in large quantities and to meet exacting specifications, no reasonable amount of control can confidently be expected without the metallographic microscope. The main immediate outlet for duralumin will be in the form of sheets, rods and tubes, and the structural changes resulting from working, heat treatment and aging can be interpreted most readily by microscopic methods in conjunction with physical tests.

In order to present a broad survey of commercial aluminum-rolling practice, together with the more important details involved, the discussion is divided into two main parts, first, the production of rolling ingots, and second, the mechanical treatment of aluminum. The various processes through which the metal passes from the time pig aluminum is unloaded from cars until the finished sheets are boxed and ready for shipment will be set forth. Unless otherwise stated, the aluminum referred to in the following paragraphs is metal containing 99 per cent Al and over (based on the difference method of analysis), with copper, silicon and iron in subordinate amounts.

Commercial Pig Aluminum

Commercial aluminum of fairly high purity is obtainable in large quantities, and such metal containing over 99 per cent Al goes into much of the present output of aluminum sheet. About 98 to 99 per cent metal is also rolled, and considerable secondary (remelt) aluminum is used for sheet manufacture. Primary or virgin aluminum is ordinarily received by the rolling mill in the form of cast pigs of various sizes and weights. Two typical commercial pigs are those known as 33-lb. (15-kg.) four-notch bars and 3-lb. (1.4-kg.) six-notch bars, but larger or smaller pigs may be furnished according to requirements.[1]

TABLE I. VARIOUS SPECIFICATIONS FOR PIG ALUMINUM

Navy Department Specifications for Ingot Aluminum

Chemical Properties: The chemical requirements shall be in accordance with the following table:

Al (Min.) Per cent	Fe (Max.) Per cent	Si (Max.) Per cent	Other impurities (Max.) Per cent	Sum of Fe and Si and other impurities. Per cent
99.40	0.60	0.60	0.10	0.60

Bureau of Aircraft Production Specification for Ingot Aluminum

Ingot aluminum shall be ordered under three grades, conforming to the following chemical requirements:

Grade	Al per cent (Min.)
Special	99.5
Standard No. 1	99.0
Standard No. 2	98.0

American Society for Testing Materials Tentative Specifications for Aluminum Ingots for Re-Melting and for Rolling

Two grades of aluminum are considered under these specifications, as follows:

A grade, containing not less than 99 per cent Al
B grade, containing not less than 98 per cent Al.

There are two well-defined grades of primary aluminum pig, viz., grade 1 and grade 2. The former is supposed to contain over 99 per cent Al, and the latter 98 to 99 per cent Al. These grades are also referred to as grades A and B, respectively. Typical specifications for aluminum pig may be cited. Table I shows the specifications of the Navy Department and the Bureau of Aircraft Production, and the tentative specifications of the American Society for Testing Materials.

[1] The nomenclature regarding forms of aluminum is rather muddled; for example, pigs are also called bars and ingots. For the sake of uniformity, metal for melting will be called pig aluminum, and metal for rolling will be termed ingot.

In connection with the extracts in Table I from the complete specifications, various instructions are given that the metal must be of uniform quality, strong, tough and sound; the specifications also state that the pig must be free from blowholes, shrinkage cracks, foreign matter and other defects. Further amplification on this subject is not considered necessary in the present article, and the writers' object in citing the above excerpts is merely for the purpose of indicating the general trend. Actually, specifications for aluminum ingot have not been entirely settled upon as yet.

The chief impurities found in the present-day commercial aluminum are copper, iron and silicon, so far as is now known, although the recent work of Rhodin[2] indicates that appreciable amounts of aluminum oxide (calculated as Al_2O_3) are usually found. Whether the quite large amounts found by Rhodin are normally present in average virgin pig aluminum is somewhat doubtful, but any difference method for aluminum based on determinations of copper, iron and silicon and omitting aluminum oxide is certainly liable to be in error. The presence of appreciable amounts of aluminum nitride, aluminum carbide and other aluminum compounds, as well as occluded particles of the reduction pot bath, is yet to be established, but apparently merits consideration. The supposition most generally held at the present time is that the normal and usual impurities in primary aluminum pig are copper, iron and silicon; these elements are usually determined in analyzing aluminum pig; the difference between 100 per cent and the sum of these elements is said to be aluminum. The writers are unable to accept this view of the matter and think that the difference represents aluminum plus aluminum oxide at least, and possibly some other compounds.[3]

As indicative of the composition of typical aluminum pig, the analyses in Table II may be consulted. With the exception of sample 10, these were all classed as grade 1. High-grade commercial metal may contain up to 99.6 per cent Al, but under the present reduction practice it is apparently not feasible to attempt any higher degree of refinement.

TABLE II. TYPICAL ANALYSES OF ALUMINUM PIG

Sample number	Percentages of Elements				
	Cu	Si	Mn	Fe	Al
1 1	0.09	0.29	nil	0.30	99.32
2	0.16	0.27	trace	0.36	99.21
3	0.12	0.34	trace	0.34	99.20
4	0.11	0.37	trace	0.32	99.20
5	0.12	0.44	trace	0.30	99.14
6	0.11	0.40	trace	0.36	99.13
7	0.18	0.40	trace	0.32	99.10
8	0.19	0.42	trace	0.31	99.08
9	0.23	0.35	nil	0.40	99.02
10	0.22	0.45	trace	0.39	98.94

Methods for Sampling Aluminum Pig

When shipments of aluminum pig are received at the rolling mill, samples for chemical analysis should be secured, and the shipments should be checked chemically on receipt. The car shipments are weighed and placed in a stock storage according to lot, and the metal is drawn out at future intervals for melting and casting into rolling ingots.

There are several methods in use for sampling shipments of pig aluminum, and these vary in accuracy with the mode of sampling as well as with the size of the shipments. For sampling carload lots or smaller lots of pig aluminum, it is necessary to select pigs at random. For larger lots, as many samples as necessary may be selected according to the judgment of the chemist, who should supervise all sampling. In any event, it is better to secure too many pigs rather than too few.

In the fabrication of sheet aluminum, where for certain grades of sheet the specifications call for all-virgin rolling ingots, it is possible to obtain a reasonable check on car shipments by analyzing samples from various casts, say the first, middle and last casts from the melting furnace charge. Of course, this will not be possible under normal conditions when scrap aluminum is charged with the virgin pig, unless the disposition of the scrap is followed; that is a difficult matter to attempt in any plant and is hardly worth while.

For 33-lb. (15-kg.) pigs, the metal should be drilled through each notch, the separate drillings well mixed, and run over with a magnet to remove any iron contamination from the drill or drill press. Sufficient of the well-mixed drillings, about 25 to 50 g., are retained for chemical analysis. Small six-notch pigs may be drilled through each notch also, in as many places as is necessary to obtain a sufficient sample. It may be advisable in cases where more accuracy is desired to melt together in a graphite crucible sufficient pieces broken from ingots, say the end and center notches, for six-notch pig; when molten, a dip sample may be taken, poured into a chill mold, and drilled in the ordinary way at numerous points. The well-mixed drillings constitute the sample. This procedure is hardly advisable except in case of dispute. Drillings should be fine, thin chips. Coarse, uneven drillings, or those which come in long curls are undesirable, since they will be non-representative in case of segregation in the pigs. Further details will not be elaborated, since this is a matter of more particular interest to chemists than mill managers.

Scrap, Briquets and Bales

A large amount of aluminum[4] is turned over annually in the form of scrap, some of which goes into melting-furnace charges for ingot production and the remainder into foundry charges for alloy castings. Roughly, the scrap aluminum produced in a rolling mill with a fabricating department may be divided into three classes, as follows:

(a) Furnace scrap, including splashings from tapping and pouring, and drippings and skimmings from crucibles.

(b) Rolling-mill scrap, made up of slab and sheet shearings; buckled slabs and sheets which have caught in the mills during rolling; and defective sheets such as those which are rejected because of occluded dross, stains on annealing, and for other reasons.

(c) Fabricating scrap, resulting from sundry fabricating processes, and including shearings, clippings and punchings from punch-press operations, chips, fine and coarse "hay" from beading and trimming operations, and so on. Melting-furnace scrap and medium and heavy rolling-mill scrap is usually returned as such to the furnace; there is little opportunity for contamination by foreign materials; they are also so massive, with the exception of shearings from light-gage sheets, as to be less liable to oxidation during melting than fine scraps.

[2] J. G. A. Rhodin, "Contributions to the Chemistry of Aluminum and Aluminum Alloys," *Trans.*, Faraday Soc., January 1919, vol. 14, pp. 134-49.

[3] There is sufficient evidence to show that other oxides may be present, but that is a matter which will be dealt with in a later paper.

[4] J. P. Dunlop, "Secondary Metals in 1917," Mineral Resources of the United States, 1917, Part I, pp. 327-29.

For economical handling, light rolling-mill scrap and fabricating scrap should be baled, and the latter possibly briquetted, although it is often charged in its original scrap condition. There is no necessity for attempting to bale large shearings, such as from slabs, plates and heavy sheets, nor do they lend themselves readily to baling. Fine fabricating scraps and long, thin shearings, such as result from re-squaring cuts on light-gage sheets, should be baled. In the case of fine "hay," it appears that briquetting might be advantageous.

A mechanical baler can form a bale of convenient weight and dimensions for charging; such a bale may have approximate dimensions of 12 x 12 x 12 in. and weigh from 15 to 35 lb. (30 cu. cm., weighing 7 to 16 kg.), the weight of a given bale being dependent upon the amount of air space.

Briquetting has been previously discussed;[5] it may, however, be advisable to point out under what plant conditions it may be economical to briquet as well as to distinguish more sharply between briquetting and baling. It is a well known fact that briquetting furnishes a metallurgical product from fine scrap which is practically equivalent to heavy scrap provided no contamination from foreign materials has arisen. However, whether a given plant will do briquetting or baling depends upon local conditions. Thus, if a plant operates a rolling mill for the production of sheets, there is obviously no need for the installation of a briquetting machine, unless large quantities of fine light scraps are purchased outside, since practically no *small* scrap results from rolling-mill operations. If most of the scrap made in the plant is medium-sized, baling will probably prove economical, provided sufficient scrap is made. Utensil-plant scrap has been successfully baled with a reduction in melting-furnace dross losses. In the event that a plant near by can do briquetting and baling, it may be advisable to send the appropriate scraps outside for treatment. Economic considerations will rule necessarily in any case. Both briquets and bales furnish good charging forms because of their convenience in handling; further, their value is increased over the value of loose scrap. Metallurgically considered, fine scraps, in the loose condition, cause high dross losses because of relative ease of oxidation, and also for the reason that these kinds of scraps are difficult of immersion beneath the surface of a molten bath. Scrap when briquetted or baled is greatly to be preferred both from the mechanical and metallurgical standpoints, but briquetting and baling can hardly be considered competitive; each has its own applications.

Part II, dealing with melting furnaces and ingot pouring, will be published in our next issue.

Movement of Tank Cars

Headquarters of the Division of Transportation of the American Petroleum Institute have been established at Room 554, 29 South La Salle St., Chicago. The organization of this department has been commenced and vigorous action is being taken toward carrying out the purposes for which it was created. Assistant directors have been appointed for field work in various territories, and everything possible will be done to accomplish results at an early date. Correspondence relative to the speeding up of the movement of tank cars should be sent to M. J. Gormley, director.

Brine Corrosion of Petroleum Equipment

By Ralph R. Mathews and Philip A. Crosby

Petroleum coming from the Healdton Field, Oklahoma, contains salt water in varying proportions, and also a small amount of sediment or silt. Most of the silt is very finely divided and when separated from the oil has a powder-like appearance. The salt water separates from the petroleum very slowly, and on standing in a tank for six months or even longer from 0.2 to 0.4 per cent is still present.

Just why the water is held in the oil so tenaciously is not exactly clear, but it appears that the finely-divided silt is in suspension in the oil and helps to support and retain the water. Due to this close association of the salt water with the petroleum, some of it travels through the pipe lines to the refineries, even though it may be in storage in the field for a considerable time. Thus the oil will probably arrive at the refinery containing 0.5 to 1.5 per cent of B. S. & W[1]. as determined by dilution, and whirling in an electric centrifuge at approximately 1,200 r.p.m. Our experience has shown this B. S. & W. is 60 to 75 per cent salt water.

To the uninitiated it no doubt seems easy to remove the salt water by washing with good, clean, warm water, or by adding a chemical which will precipitate the objectionable salts from the water and in turn from the oil. The difficulty arises here in getting an intimate mixture between the water or aqueous solution and the tiny drops of water in the oil, which probably have a protecting oil film around them. Chemicals which break down this surface tension and would thus free the drops of water have been successfully applied to the treatment of B. S. from tank bottoms, but their application to crude oil has not given the desired results. It is probable that the large volume of oil in comparison with the small amount of water is responsible for the negative results obtained. Various methods of electrical dehydration have also been applied to recovering oil from B. S. and petroleums of high water content. The reduction, however, is generally not below 1 per cent B. S. & W., thus leaving too large amount of the objectionable salt water. The centrifuge will probably reduce the B. S. & W. to 0.3 to 0.4 per cent, but its application is expensive, and there would still be enough salt water remaining to cause the trouble indicated below.

A typical analysis of the brine shows the following figures:

	G. per liter	Grains per U. S. Gal.
SiO_2	0.008	0.44
R_2O_3	0.127	7.42
$CaCO_3$	0.074	4.33
$CaSO_4$	0.011	0.64
$CaCl_2$	4.275	249.72
$MgCl_2$	1.526	89.15
NaCl	61.140	3572.20
Total solids	67.161	3923.90

The above indicates approximately a 6.5 per cent solution of sodium chloride, and special attention is directed to the content of magnesium chloride.

Observations of Corrosion

The results outlined here were obtained at a refinery where the petroleum is pumped through stills and heated to the desired temperature. The mixture

[1]B. S. & W. is an oil man's term and is interpreted as bottom settlings and water. Thus it really means the per cent of water, silt and other foreign matter in the oil.

of oil and vapors passes into an apparatus which allows the vapor to separate from the residual oil (fuel oil.) The vapor then passes through a series of dephlegmators, where it is fractionally condensed. Thus from the top of the last dephlegmator the lightest vapor passes through a condenser and the gasoline flows from there into the receiving house. Lines lead from the other dephlegmators through coolers and into the receiving house, where the necessary "cuts" are made.

The dephlegmators are arranged with water coils in the top, and after a few months service these coils began to leak. Later the tubes of the condensers started leaking water into the gasoline. Investigation showed excessive corrosion had taken place and one hole over an inch in diameter was found in a water coil when the dephlegmator top was removed.

Some of the rusty deposit found at the points of worst corrosion was removed to the laboratory and examined. It gave a slightly acid reaction and consisted largely of ferrous iron and chlorides.

Acidity of Oil Vapors

On the bottoms of the last two dephlegmators were steam lines and valves which had never been used. The lines were at the lowest points of the bottoms and any aqueous condensate would have a tendency to collect in them. There was a slight leak around the valves on these lines and a deposit showed a distinctly acid reaction and was found to consist mostly of ferrous iron and chlorides. Thus the indications pointed to corrosion by hydrochloric acid, and in order to try further to substantiate this theory a water line was tapped into the top of the next to the last dephlegmator. By means of it a small amount of water was forced down through the up-coming oil vapors. The water was trapped out in the receiving house and a sample obtained. This was examined in comparison with a sample of water taken before going through the dephlegmator and was found to have acquired an acidity equal to 8.23 grains of HCl per gal. of water.

Laboratory distillations of the oil were made, using a glass flask, and the water recovered was found to contain a small amount of hydrochloric acid. In one extreme case enough acid vapors came over during a laboratory distillation to turn blue litmus red when it was moistened and held at the mouth of the bottle containing the gasoline. The water recovered in this case was titrated, and calculation showed that the acid formation would be at the rate of 0.012 g. of HCl per liter of oil.

In view of the above evidence there seemed little doubt hydrochloric acid was responsible for the rapid corrosion, and the next step was to locate its source.

Action of Magnesium Chloride at High Temperatures

In looking for the source of the hydrochloric acid, the magnesium chloride in the salt water seemed most likely the cause. Molinari[2] states that "magnesium chloride volatilizes at a red heat and partially decomposes in the presence of minimal quantities of water, forming hydrochloric acid and magnesium oxychloride." This reaction starts at as low a temperature as 175 deg. C. If the reaction is carried to completion the ultimate products would be hydrochloric acid and magnesium oxide.

Stillman[3] says of magnesium chloride: "The latter compound, while not scale forming, is considered an active corrosive agent upon the supposition that at the temperature of 100 deg. C. and higher it is decomposed and hydrochloric acid formed and liberated."

The oil in passing through the stills is heated to approximately 260 deg. C., and at this temperature a large amount of the magnesium chloride present in the salt water in the oil is without doubt decomposed and hydrochloric acid formed. Then the acid vapors are carried with the oil vapors into the dephlegmators.

Final Observations and Conclusion

It was noted that most of the corrosion took place in the last two dephlegmators and in the condensers used with the last dephlegmator. It seems that is due to higher temperatures in the preceding dephlegmators. Thus in the next to the last dephlegmator the temperature drops to approximately 110 deg. C. and the most severe corrosion was noted on the water coils where there must have been a cooling below 100 deg. C. Some water vapor is always associated with the oil vapors, and it no doubt condenses on these water coils. The water readily collects the acid vapors and reaction starts on the metal at that point. Some of the acid vapors also carry over into the condensers, eventually causing them to give way.

We have noted this action from salt water in Healdton petroleum, but are of the opinion that petroleums from other fields could cause the same trouble, provided they carried even small amounts of salt water containing magnesium chloride.

By way of summing up, the following may be stated as covering this case in brief:

Hydrochloric acid is formed from magnesium chloride in salt water present in Healdton petroleum during distillation.

Oil vapors which contain the above acid vapor cause corrosion and produce rapid deterioration of the fractionating apparatus.

With Healdton petroleum containing 1 per cent of salt water, the amount of acid produced may be as large as 3.39 lb. of hydrochloric acid per 1,000 bbl. of oil.

Acknowledgment is made to Dr. F. W. L. Tyderman, superintendent of this refinery, for encouragement and advice in carrying out this investigation.

New Paper Fibers

A new and very strong paper fiber has been discovered in Mexico which consists of the macerated bark of a tree called *cuazuma* or *cuahulose*. The tree is abundant in the State of Jalisco, and its bark is sometimes 20 to 30 cm. in thickness. It may be produced, it is said, at low cost.

Another promising paper material is from the leaves of a tree, *Chamserops humilis*, locally known as *doum*, which grows along the coast of Morocco in easily accessible regions. It is a dwarf palm that matures rapidly, and the annual product available is reported at about 100,000 tons. The pulp contains 75 per cent actual fibers which average 2.5 x 0.01 mm. It has satisfactory felting power, thick membrane, great tenacity, complete homogeneity, and great suppleness. The raw material may be obtained at from 3 to 5 fr. per 100 kilos.—*Le Papier*, vol. 22, p. 175 (1919.)

A Classification of Filter Plates and Frames and Their General Usage

A Description of the Basis of Classification of Filter Plates—Flush or Recessed Types With Port or Cock Outlet Subtypes—Plain, Simple or Thorough Washing Arrangements With or Without Separate Outlets for Wash Subarrangements

By D. R. SPERRY

THERE are a great many different arrangements of filter plates and frames in use at the present day, but there has previously been no attempt to classify them scientifically. In the past the various types and arrangements have been indicated by empirical numbering or by such loose designation as "two-eyed," "three-eyed," "four-eyed," etc. The former is unscientific, because it is empirical; the latter is unscientific, because the designation is not exact, as it can be shown that the mere statement of the number of eyes which a plate has does not designate any particular type or arrangement. A two-eyed plate, for example, may be used for more than one purpose.

The object of this article is to present a classification of filter plates and frames by means of which all of the various types and arrangements which are in use at the present day can be easily enumerated. It is also desired to show in a general way what is the purpose of these various types and arrangements, so as to guide chemists, chemical engineers and others in an intelligent selection of the proper filter press for their problems. It should be understood that the classification here given does not apply to any particular make of filter press, but applies to all makes and is general.

Basis of the Classification of Filter Plates

The whole family of plates and frames used in the industries can be divided into two types—the recessed and the flush types. The recessed type plate is a plate which has a recess on each surface, usually about five-eighths of an inch deep, though in some cases thinner, while the flush plate has no recess at all, but is flush from edge to edge. Referring to the chart, Fig. 1, one will find on the left hand edge under the general heading of "Type" the words "Flush" and "Recessed." The whole family of commercial plates is included in this diagram and the plates belonging to the recessed type are all of those above the horizontal dividing line, while those belonging to the flush type are those below the horizontal line.

In practice it will be found that in addition to the two types of plates there are three different arrangements known as plain, simple washing and thorough washing. Again referring to the chart, one will find on the upper edge the word "Arrangement" and under this, the words "Plain," "Simple Washing" and "Thorough Washing." These three arrangements divide both the flush and the recessed types.

It will now be found that there are smaller subdivisions to both the "Type" and "Arrangement." Referring to the subdivisions under the "Flush" type and the "Recessed" type, these merely refer to the kind of outlet employed; that is, whether it is a cock outlet or a port outlet. This is very simple and needs no further explanation.

Referring to the subdivisions under "Arrangement," one will find under the heading of "Simple Washing" two divisions, one "Without Separate Outlet for Wash"; the other, "With Separate Outlet for Wash." The same two subdivisions will be found under "Thorough Washing." The meaning is quite clear.

It will be found that in this classification there appear certain blank spaces. These spaces, like the blank spaces appearing in the periodic classifications of the elements, may some day be filled, but at present they are not, at least as far as actual use in the industries is concerned.

It should be borne in mind that the type and arrangement of a plate has nothing whatever to do with the kind of surface on the plate nor does it have anything to do with the position in which the eyes or grommets are placed nor of the material of which the plate is constructed. The classification refers strictly to the type and arrangement and does not take into consideration such external characteristics as these things. For instance, the No. 11 plain plate, in the upper left hand corner of the diagram, would still be the No. 11 plate even if the surface was of the pyramid type and the grommet was in the center instead of in the upper left hand corner.

To recapitulate, all plates may be divided into two types, "flush," and "recess." Further, either of the two types may be divided into three general arrangements, "plain," "simple washing" or "thorough washing." This is the basis of filter-plate classification.

Usage of the Different Types of Plates

In solving a filtration problem it is always well to try tentatively the recessed type. It is always best to use the recessed type if it is applicable, because its first cost is less than the flush type due to the fact that flush type plates must invariably have frames, whereas the recessed type does not have to have frames. Suppose, for example, it is desired to clarify a certain vegetable oil. We would first investigate the possibilities of the recessed type for this purpose. We find, however, that in order to filter this particular oil it is necessary to use filter paper, and if this is carried out with the recessed type of plate, the paper will break due to the strain set up by the corners of the recess. This at once discards the possibility of using the recessed type of plate; therefore the flush type must be used, as in the flush type of plate the paper can lie flat and will not be subject to strains around the edges.

Suppose, however, that another problem occurred; namely, the filtering out of fullers earth from lard. In this case heavy canvas is used for a filtering medium and lard has no particularly deteriorating effect upon the fabric. It is therefore practical in this instance to use the recessed type of plate.

In a third case, one might have a problem in which a substance is to be filtered, the solids of which are bulky and porous; such, for example, as a mixture of mash and wort. Trying tentatively the recessed type of plate, one will find that it can not be employed in this instance due to the fact that the maximum recess which practice has shown to be possible, namely, three-quarters of an inch, will not produce a cake thick enough for this material, which will easily form a cake perhaps 3 or 4 in. thick. This at once discards the recessed type and makes the problem one involving the flush plate and frame type.

Another problem might be that of filtering a mixture of graphite water and clay such as is used in the manufacture of "lead" for lead pencils. In this particular problem it is necessary, due to the denseness of the solids, to filter a long time at a constantly rising pressure which may run to above 200 lb. per sq.in. It is desirable and indeed necessary in this case to have the cake very thin, possibly not more than three-eighths or one-half an inch. This at once throws the problem into the recessed type, as it is not practical to make a frame thin enough to produce the sized cake desired, but it is very practical to make a recessed plate with a shallow recess.

Still another problem might be the filtration of a certain aluminum salt which is strongly alkaline. Trying the recessed type for this problem, it will be found that the cloths would soon break around the edges due to the recess, as it is a fact that strong alkali has a rotting effect upon the fibers of the cloth. This discards the possibility of using the recessed type and puts the problem into the flush type, where there is little or no sag around the edges of the filtering surface.

Usage of the Different Arrangements of Plates

These five problems show in a general way how one arrives at the proper *type* of plate to use. After the type has been determined, it is next necessary to find out what arrangement is wanted. If the material to be filtered does not have to be washed, the arrangement is to be of the "plain" type. If, however, the material to be filtered has to be washed, then it must be either "simple washing" or "thorough washing." The physical and chemical characteristics determine which of these two types of washing should be employed. For example, if the material to be filtered is of a very dense nature, so dense in fact that a reasonable filling time builds up a cake on each chamber surface not thick enough to join the solids on the adjacent sides of the chambers, simple washing should be employed; that is to say, the wash water is introduced along the same channel that the material to be filtered entered. In this instance, if thorough washing is used, an excessive strain would be put upon the cloth on the surface corresponding to that surface of the plate against which the wash water is introduced, due to the fact that the cloth would be obliged to sag until it was supported by the solids deposited. In simple washing, however, this objection is entirely eliminated. Furthermore, the solids, through

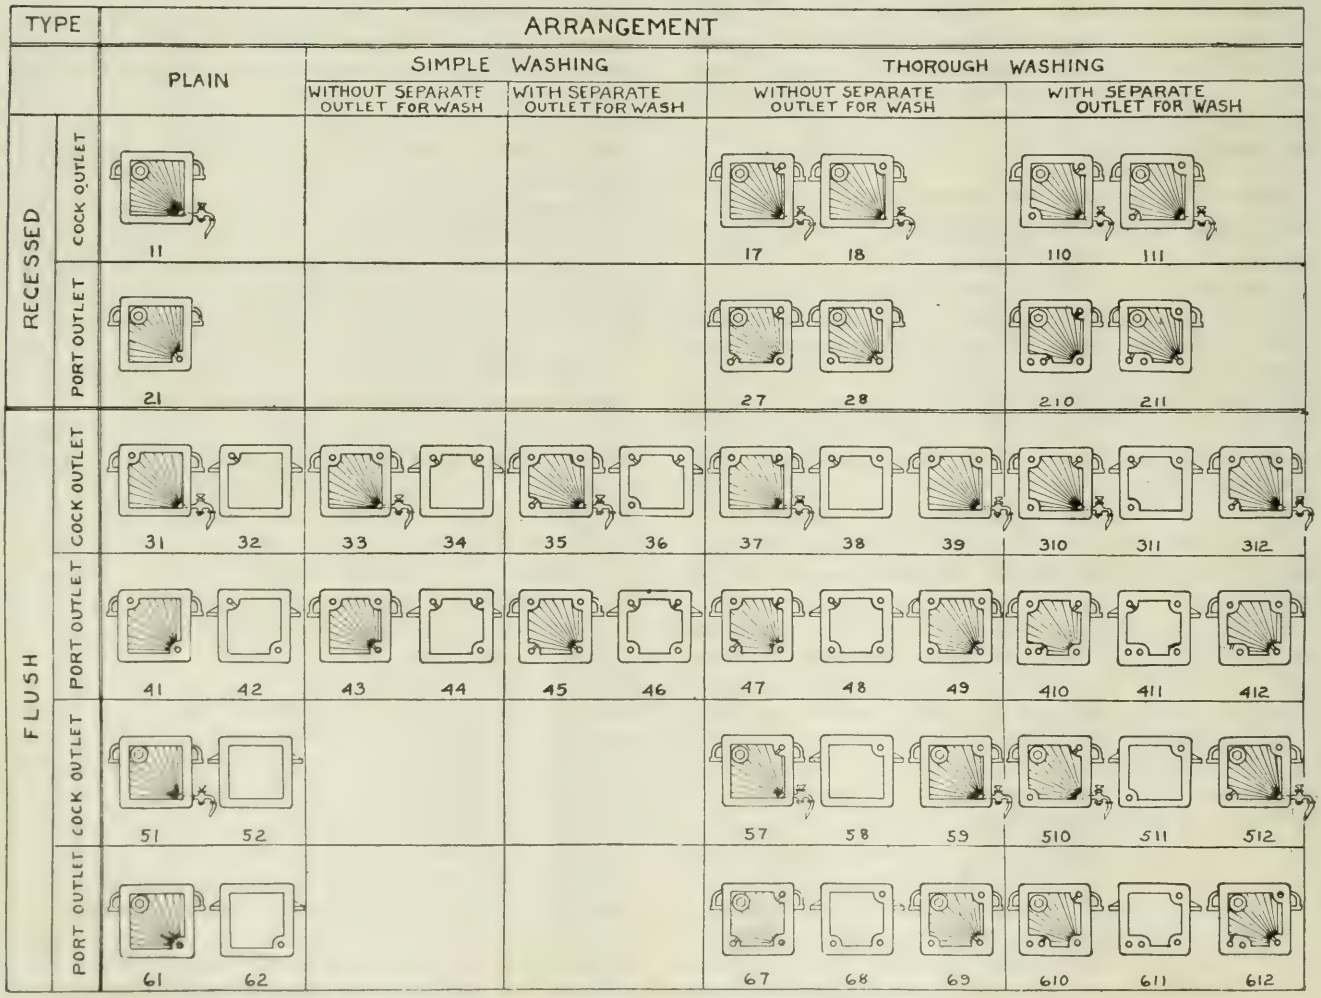

FIG. 1. CLASSIFICATION OF FILTER PLATES, TYPICAL PLATES AND FRAMES

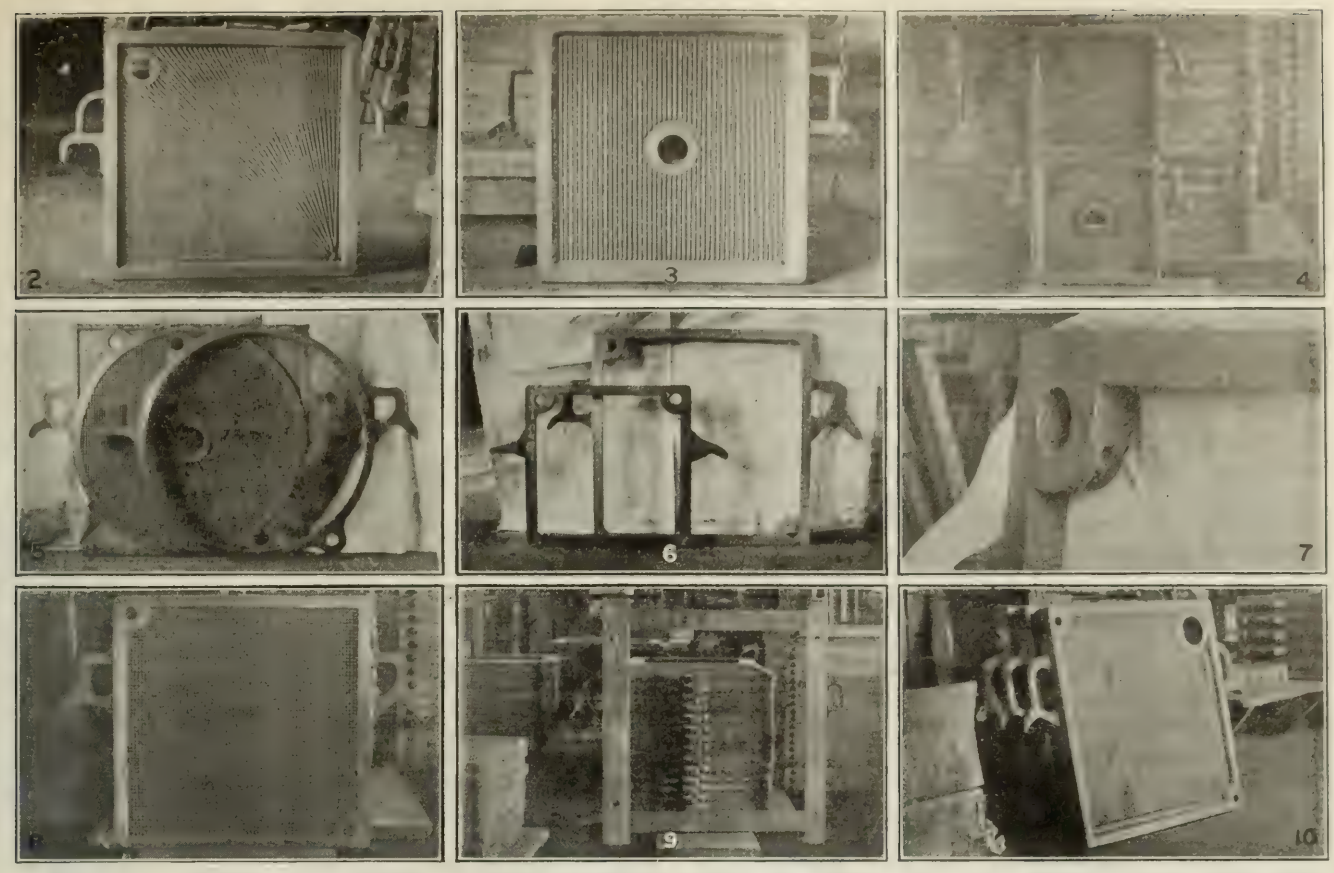

Fig. 2—No. 11 plate, radial grooved surface, corner feed. Fig. 3—No. 11 plate, parallel corrugated, center feed. Fig. 4—No. 11 plates; above, pyramid surface, center feed; below, radial grooved, corner feed. Fig. 5—No. 31 plate, No. 32 frame. Fig. 6—Small frame, No. 38; large frame, No. 32. Fig. 7—"Close-up" showing connection between eye and interior of frame. This is a feed eye; a wash eye would have no port leading to interior of frame. Fig. 8—No. 31 plate, pyramid surface. Fig. 9—No. 38, wood frame. Fig. 10—No. 11 steam-heated plate, parallel corrugated. Small eyes are for steam inlet and outlet.

which the wash water has to pass, are one-half as thick in the case of simple washing as in thorough washing, and since the solids are assumed to be very dense, this reason alone would warrant the use of simple washing.

On the other hand, suppose that the material to be filtered and washed will, in a reasonable filling time, entirely occupy the chambers of the filter press. If we were to try simple washing in this case, we could scarcely reach the solids at all but come in contact merely with those solids next to the feed port. It would therefore be necessary to use thorough washing.

Usage of Port or Cock Outlets, Subtypes of Plates

Treating now the sub-headings appearing under the words "Flush," "Recessed," "Simple Washing" and "Thorough Washing," the determination as to whether the outlet should be a cock outlet or a port outlet depends upon various things. If one were to filter a substance the liquid of which was highly volatile and valuable, such as alcohol or ether, it would be inadvisable to use a cock outlet, on account of the loss by evaporation. This would immediately demand a closed discharge so that the volatile filtrate could be conducted to a closed vessel without contact with the atmosphere. In the case, however, where there is no danger of loss by evaporation, the cock outlet is ordinarily used. The cock outlet or open discharge, as it is sometimes called, should always be employed if possible, because in case of breakage of a cloth the whole filtering operation will not be interrupted as in the case of closed discharge, but the operator merely turns off the cock which runs cloudy and goes on with the process.

Whether or not there should be a separate outlet for wash depends upon several conditions. Frequently it is desired to have a permanent wash outlet pipe connection which runs the wash water to some desired point. Oftentimes where thorough washing is employed, a valuable volatile substance may be the washing liquid instead of wash water. It may be some solvent, such as alcohol. In this instance, every other cock washing system would be out of the question owing to the loss by evaporation, and a separate outlet for the wash would be necessary.

The every other cock washing system, which is thorough washing without separate outlet for wash, is generally desirable, because in the case of a cloth giving out it can be at once detected by the eye or by chemical and physical tests; otherwise, it is not likely to be found out until considerable damage results.

Other Systems of Plates

The above classification, as already stated, covers those plates and frames most commonly used in practice in the United States. There are other systems which could be added, but owing to the fact that they are so rarely used, they are here omitted. One of these is the "three-plate system." We have not included this, as it is almost unknown in the industries and would therefore merely serve to complicate the classification.

There may be other eyes in a plate and yet those eyes would have nothing whatever to do with the type or arrangement. A case in point is that of the hollow or steam-heated plates in which there may be an eye for the entrance of the steam and an eye for the drip.

This would add two eyes, but would not in any way affect the type or arrangement of the plate. Again, it may be desired to have two separate outlets for the filtrate, thus adding another eye. This would not in any way affect the type or arrangement, but would be the same as though there were but one outlet for filtrate. A No. 11 plate with two outlets would still be a No. 11 plate; a No. 21 plate with two eyes in the lower corner, both of which are outlets for filtrate, would still be a No. 21 plate.

It will be found occasionally in practice that frames are used with recessed plates. This is not good practice and is not necessary in any event. Where this arrangement is found, it is usually due to the fact that recessed plates were originally purchased and later it was desired to increase the cake thickness and this was done by inserting No. 52 frames between the plates, or it may be that the press was made up that way originally in order to make use of certain stock material in cases where delivery is the paramount question, but in general there is no excuse whatsoever for a recessed plate with frames.

Description of the Plates

The writer has included in this article a number of illustrations showing the appearance of various typical plates and frames, the number of which is in each instance given.

Figs. 2, 3, 4 and 10 all show pictures of No. 11 plates. Here we find three different plate surfaces, radial, parallel corrugated, and pyramid; furthermore, some have the feed in the upper corner, while others have the feed in the center. Yet all are No. 11 plates. Fig. 9 is discussed later.

Fig. 5 shows a round plate and frame with grommet hole and two eyes with cock discharge. One would be inclined to regard this as belonging to the 510-11-12 series, but as a matter of fact it is a No. 31 plate and No. 32 frame. The lower eye is the feed channel; the upper eye is a circulating feed return, while the central opening is for the purpose of supporting certain mechanical features. Designating this plate as two- or three-eye would be far indeed from telling to what system it belongs.

Fig. 6 shows two frames; both have two eyes, and since they both serve entirely different systems, to call them two-eyed frames would tell very little. The small frame is a No. 38 frame; one eye is for feed, while the other is for wash water. The large frame is a No. 32 frame, as both eyes are for feed. The one feed eye ordinarily used is split into two separate eyes. Examination of these two eyes would disclose a port leading into the interior of the frame in each case (Fig. 7).

Fig. 8 is a No. 31 plate. The large frame shown in Fig. 6 is used with this plate.

Fig. 9 is a No. 38 wood frame; one would imagine that it was a No. 311 frame, but it so happens that the large eye is the feed eye, while the two smaller eyes are both wash inlets. Here the ordinary one eye used for washing is divided into two eyes.

Fig. 10 is a No. 11 steam-heated or hollow plate. Seemingly this is a No. 110 or No. 111 plate, but the two small eyes are for the purpose of conducting steam to the interior of the plates and removing the drip, and have nothing to do with type or arrangement, therefore for purposes of classification are negligible.

Batavia, Ill.

Photo-electric Spectrophotometry

In connection with the color-standardization work of the Bureau of Standards, it is desired to have available a number of independent methods of making spectrophotometric determinations, especially in the visible part of the spectrum, for it is generally admitted that the fundamental basis of color specification is spectrophotometry. To supplement the color methods at present in use at the Bureau, and especially to overcome the well-known uncertainty of measurements made in the blue and violet, a method for accurate and convenient photo-electric spectrophotometry, suitable for routine determinations, has been developed, which has proven very satisfactory as to speed of operation, ease of keeping in working condition, and reliability of measurement.

The null method used has made it possible to eliminate many errors common to photo-electric deflection methods. The only variable in the process of making a determination of the transmission at any wave length is the accurately measurable distance of a small light source from the slit of the spectrometer. Measurements of spectral transmission can be made from 380 millimicrons in the extreme violet to about 650 millimicrons in the red.

Measurements of diffuse spectral reflection relative to that of magnesium carbonate have also been made. In addition, the method is applicable to the measurement of the relative radiant power of two sources and to the measurement of fluorescence, and could be extended into the ultra-violet if quartz parts were used instead of glass.

Traveling Exhibition of Canadian Goods in France

An exchange of exhibition trains for showing in one country the products of another is a recent trade-extension project that is attracting attention in Canada. The Canadian National Railways have arranged for the transportation of exhibits of French goods through Canada, and Canadian manufacturers will be able to secure a similar exhibition of their goods on a train that will be taken through the principal cities of France.

France, it is stated, is badly in need of commodities that can be supplied by Canada, especially shoes and woolen underwear. There is an immediate need of immense quantities of such goods, which the industries of France cannot produce in sufficient volume for some time. The view is taken that it is necessary only that Canadian goods should be known in order to find a larger market in France, and the plan of a traveling exhibit has everything to recommend it.

Sizes of Feet

Commerce Reports of Feb. 11, 1920, contains the following information on "Measurements Used in Exporting Swedish Lumber":

"According to Trade Commissioner Axel H. Oxholm, 69 per cent of the lumber exported by a company in northern Sweden is cut to English feet, 7 per cent to Danish feet (1 Danish foot = 0.9711 English foot), 8 per cent to "metric feet" (1 metric foot = $\frac{1}{3}$ meter = 1.0936 English feet), 7 per cent to Spanish feet (1 Spanish foot = 1.0783 English feet), 4 per cent to Dutch feet (1 Dutch foot = 1.0768 English feet), 4 per cent to German feet (1 German foot = 1.0639 English feet), and 1 per cent to decimeters (1 decimeter = $3\frac{15}{16}$ English inches)."

PRESENT PLANT OF THE COLLINSVILLE ZINC CORPORATION

Making Lithopone at Collinsville, Ill.

Historic Zinc Smelting Plant of the Collinsville Zinc Corporation Rehabilitated for the Manufacture of Lithopone—High Price of Paint Base Interested Capital in Converting Old Industry to New Manufacture in Works Long Idle—First Unit in Successful Operation

BY CHESTER H. JONES

THE original plant on the property of the Collinsville Zinc Corporation was erected in 1873 by Dr. Octavius Lumagi at Collinsville, Ill., eleven miles east of the Pennsylvania R.R., for the purpose of utilizing as fuel the refuse slack from the coal mines in the immediate vicinity. One small set of Belgian block furnaces, a hand-operated blende-roasting furnace and a limekiln for burning zinc carbonate constituted the original works. In 1878 Otto F. Meister and Henry Wyman leased the Lumagi plant, purchasing five additional acres of land. New block furnaces were constructed and in 1890 the first Brown horseshoe roasting furnace in the world was erected by Herman Brown. This furnace has been put in operation with the remainder of the works under the present management.

Fig. 1 illustrates the original plant as installed and is a good example of the printer's art of that time in portraying industrial activity. It illustrates the ideas of other days in what was then regarded as "some project," recalling much of the romance surrounding the development of the zinc industry of America.

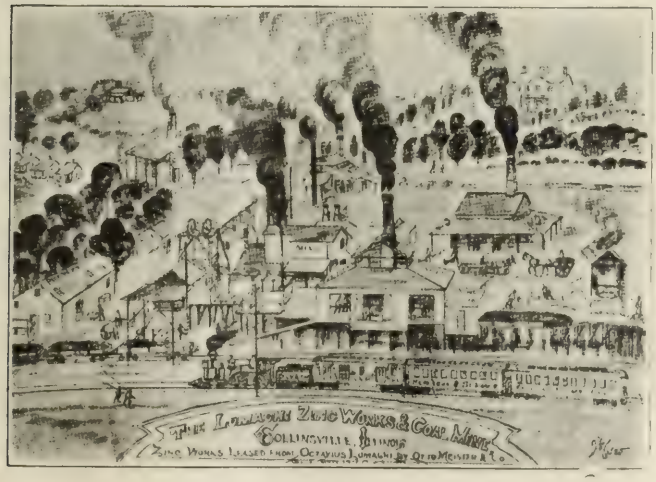

FIG. 1. THE ORIGINAL ZINC SMELTER

A touch of the personal interest of the old employee in his business is also evidenced in the return of Ben Raymond, now a successful bank director in the district, who was connected with the works as superintendent during the first period of activity. Regardless of other interests, he came back on his own initiative to start the old furnaces when the new company commenced operations.

The Collinsville Zinc Corporation secures the zinc ore from its Lost Hill mines at Moselle, Mo., which have about 300,000 tons now "in sight." The lithopone manufactured at the present works, shown at the head of this article, made from a combination of this ore with barytes, is used in manufacturing paints, enamel, rubber tires, linoleum, shade cloth, wall paper, printing inks, etc. Its production is described in the following paragraphs.

Present Plant

The plant as it exists today comprises ore and coal mills, five Brown horseshoe furnaces (sixth under construction), nine Belgian block furnaces, leaching plant, lithophone driers, and finishing plant, pottery kilns, power plant and necessary shops. The leaching and lithophone drying plants with necessary conveying equipment are additions to the zinc-smelting equipment for making lithophone and the first units with a 30-45-ton capacity of lithophone per 24 hr. are in operation. When the proposed schedule is carried out a total quantity of 300 tons per day will be produced.

Lithophone Manufacture

The zinc ore is shipped from the company's mines and unloaded from cars to the stock piles near the mill, while the barytes comes from southeastern Missouri points less than 100 miles distant. The largest barytes deposits in the United States are in this district. These

two raw materials are consumed in the ratio of 30 per cent zinc ore to 70 per cent barytes.

The zinc is fed to a baffle drier which consists of a short brick stack about 6 ft. square fired from beneath, the ore being intercepted by horizontal baffles in its downward course. It is received at the bottom by a jaw crusher (Blake) and subsequently enters corrugated rolls where it is reduced to pass 10-mesh screen, and is finally elevated to a storage bin.

It is removed from this storage by hand to narrow gage tramcars similar to those used in ore mines and is conveyed about 100 ft. across to the receiving hoppers which feed each pair of Brown furnaces.

Zinc Roasting

These furnaces have a 10-ft. hearth constructed on a circle with the inner edge of the hearth built on a 70-ft. diameter. The inner wall is shown in Fig. 2. Openings for inspection and repairs are provided on both walls with buckstays between. The post in the foreground is near the center of the circle. The ore occupies a time of 20½ hr. in passing through the length

FIG. 2. INTERIOR CIRCULAR WALL OF BROWN FURNACE

of the furnace. Capacity of each furnace is about 1,000 lb. (408 kg.) per hr. of roasted ore having a sulphur content of less than 3 per cent.

Fig. 3 shows the feed end where the hopper gate is automatically tripped to deliver ore to the hearth over the chutes, as appears to the left of the wooden post. The rabbles are operated by steel cable guided in sheave pulleys. About 3 hp. is required to drive the entire rabble mechanism, which travels through the furnace at 1½ min. per revolution. The fire stack connection is located near the feed end.

Heat is supplied from three fireplaces, two located at discharge end, farthest away from stack, and one near the feed end. This is varied on some of the furnaces by having five fireplaces, three being near discharge end and two near the stack. Powdered coal is used for fuel. Firebrick is used throughout in construction of the furnace.

Fig. 4 shows the discharge end of the horseshoe with a rabble arm emerging beneath the sheet-iron door. The door is hinged to open by pressure of the carriage. When one of these rabbles comes into the open space or end of the horseshoe, between the discharge and feed ends of the hearth, it is automatically detached from the driving cable; at this moment another carriage, which has been cooling in the space, is automatically attached and is carried into the feed end of the furnace.

While the roasted ore, consisting of ZnO and $ZnSO_4$ (the latter from residual moisture), was previously removed by hand tram, on track shown in foreground,

FIG. 3. FEED END BROWN FURNACE

Fig. 4, provision is being made to form a slurry with water and pump to the leaching plant, 150 ft. distant.

Leaching the Partly Roasted Zinc

The slurry is carried over to the leaching plant, where it is distributed to each of 6 wooden tanks, 8 ft. diameter x 10 ft. high, and provided with drop bottoms for removing sludge on completion of the lixiviation. This series of tanks is arranged in a cascade at the top of which is a larger wooden tank, lead-lined, containing a 20 per cent solution of H_2SO_4, being made by diluting chamber acid. This solution is fed to the cascade. All the tanks are heated by steam coils. The solution of zinc sulphate thus produced is pumped to six 14 ft. diameter x 10 ft. high wooden neutralizing tanks equipped with steam coils for keeping at boiling temperatures. The exact method at this point is not revealed. The neutralized zinc sulphate liquor is then ready for mixing.

Barytes Treatment

The barytes is carried from the stock piles by screw conveyor to an Allis-Chalmers No. 2 Pulverator. The section of screw conveyor feeding the pulverator is steam jacketed for drying the barytes. The pulverized material is fed to the boot of a steel elevator, where 30 per cent powdered coal is added and the mixture elevated to four steel hopper-bottomed storage bins. Tramcars convey from these bins to the Belgian block furnaces. Here the barytes ($BaSO_4$) is roasted to barium sulphide (BaS), the coal in the mix acting as a reducing agent. Detail of these furnaces will be covered further on.

The BaS thus produced is known as black ash or water-soluble barium sulphide. This is mixed in a

FIG. 4. DISCHARGE END OF BROWN FURNACE

slurry and pumped back to the leaching plant, where the solid is removed in a Cyclone classifier (about 2 ft. in diameter) and the water returned to the furnaces. Only a small amount of BaS goes into solution during transportation.

Leaching Black Ash

The black ash sludge drops from the Cyclone to the center of the first of three leachers arranged in series. These leachers are steel tanks about 15 ft. in diameter and 15 in. high. Each tank is divided by concentric steel walls so spaced as to form six annular channels of equal width between center and sides. Within each

FIG. 5. FIRST DRIER UNIT

channel a shoe or paddle is suspended from the arms slowly rotating above the tank.

Clear water flows in at the center together with the black ash as referred to above and the solution flows outward over each partition, while the solid is carried along in part so that a thorough mixing results. At the final outlet of the series of tanks practically all of the BaS is carried in clear solution. The water is heated by steam during process. This is said to give more thorough leaching results than any other method so far attempted. The clear liquor is pumped to five 10 ft. diameter x 15 ft. in height steel storage tanks and the residual sludge returned to the Belgian block furnaces.

Mixing Solutions to Produce Lithopone Liquor

The clear liquors of neutral zinc sulphate and barium sulphide are pumped from their respective storage tanks to four 8 x 10 ft. wooden tanks equipped with slowly revolving agitators and mixed in the proportion of 30 per cent zinc to 70 per cent barium content. These tanks are located in the first drier building adjoining the leaching plant.

The resulting solution is pumped to the 8 x 6 ft. Oliver filter located above the drier shown in Fig. 5. The filter delivers over the splash board shown in the upper part of the picture just to the left of the center.

The driers, of which there are two complete units located in separate buildings, are each composed of a circular brick structure about 20 ft. outside diameter and 3 ft. high. A floor of brick supported by arch construction is built 6 in. from the top to form a shallow pan over which the material is moved by rabble arms equipped with shoes as shown in Figs. 7 and 8. Heat is applied by coal fire from beneath. The revolving arms are constructed of steel I-beams and the mechanism and drive suspended from above. Hoods of sheet iron over each arm prevent the material from dropping directly on the rabble. A 10-hp. back geared motor drives the whole.

The filter is driven by a 2-hp. motor and the vacuum maintained by a 9½ x 8 in. Doak vacuum pump. A steel bin (shown in the upper right hand Fig. 5) receives the dried material from the first unit.

Belgian Block Furnaces

After the initial drying the powdered substance is trammed to the Belgian block furnaces, where it is calcined at a temperature of about 900 deg. F. (480 deg. C.), red heat, and quenched in water while hot. Proper quenching is the key to successful operation, as the reaction must not be allowed to proceed too far.

There are nine double Belgian block furnaces, each half furnace containing 128 retorts, or 256 retorts per furnace. Each retort receives about 100 lb. of material. The two fireboxes are fired by hand with ordinary stoking coal. Fig. 6 shows a section of one face of the furnace with the refractory lids in place over each retort. The sheet iron cover on the floor is removed when discharging and the material raked from the retorts falls into the quenching pit beneath.

The retorts are supported at the ends in the walls with space around each retort to permit heat to circulate unobstructed and facilitate removal of individual retorts for repairs. Each block furnace is equipped with two stacks, and two fireboxes, one set for each face. A vertical firebrick wall separates the heat chambers.

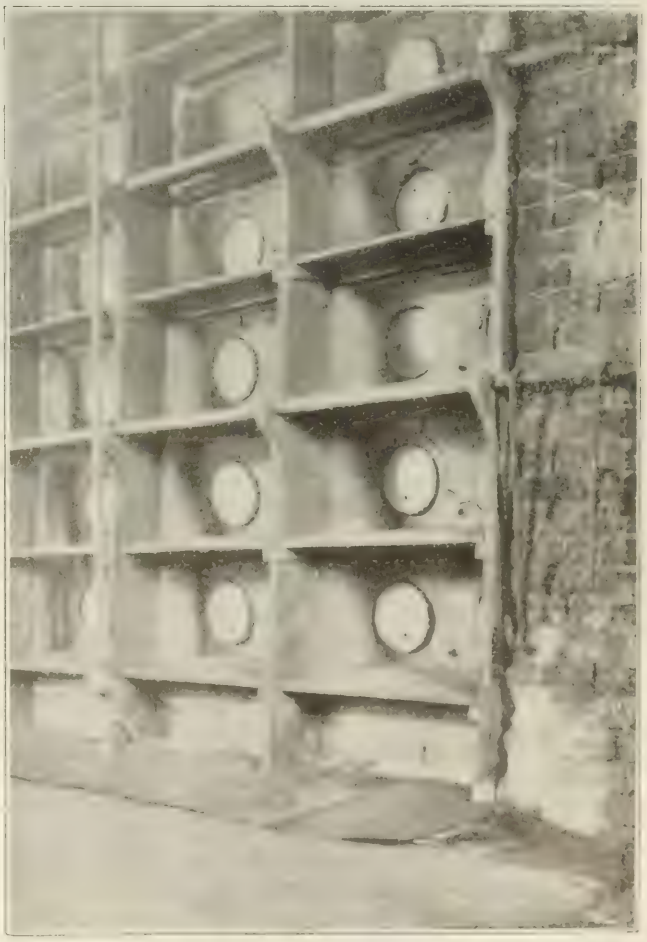

FIG. 6. SECTION OF FACE OF BELGIAN BLOCK FURNACES

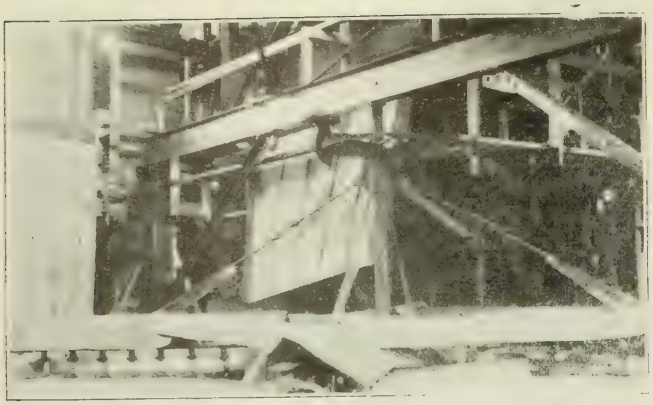

FIG. 7. SECOND DRIER IN FINISHING PLANT

The slurry formed by quenching of the calcined lithopone is pumped to the second drying unit in the finishing plant, where it is passed through an Oliver filter wheel (12 x 8 ft.), the delivery board of which is shown in the center of Fig. 7.

It will be noted that the drier is driven by chain and bevel gears. Fig. 8 shows brick construction and details of rabble plows.

After the final drying the finished material is removed from the drier bed by screw conveyor, fed to a Fuller-Lehigh mill, where it is ground to pass 300 mesh, elevated to wooden storage bins, whence it is drawn through chutes and packed in wooden barrels, lined

FIG. 8. LITHOPONE DRIER BED AND PLOWS

with paper bags, for the market. The commercial lithopone thus marketed analyzes about 30 per cent ZnS and 70 per cent $BaSO_4$.

Future

With the condition of the market such as to demand this product for paint base at high prices, this adaptation of the plant is timely. The new construction work during the coming season will call for added supplies of paint pigments.

The ultimate development of this plant to full capacity of furnaces will call for a period of construction and involve considerable additions in equipment and machinery. The work is proceeding under the direction of A. F. Versen, general manager, assisted by H. E. Gillaspy, general superintendent.

We acknowledge the many courtesies extended by Mr. Versen during the preparation of this article.

Directory of Special Libraries

The Special Libraries Association is enumerating the special library collections of the country, for the purpose of preparing an adequate directory of special libraries. A work of this nature will be as useful to librarians and investigators as a directory of manufacturers is to the purchaser of machinery or supplies. It will be a census of special information sources in the United States.

A special library has been defined as:

"A good working collection of information upon either a specific subject or field of activity; it may consist of general or even limited material serving the interests of a special clientèle; and preferably in charge of a specialist trained in the use and application of the particular material."

Any company having such library is requested to assist in the compilation of the directory by sending in the following information:

1. Name of institution or company.
2. Name by which library is known.
3. Name of librarian or custodian.
4. Can it be classified as any of the following: financial; business; legal; engineering or technical; institutional; municipal; reference; agricultural.
5. If not, how can it be classified?
6. Does it serve a special clientèle?
7. Would your librarian be willing to assist other special libraries to a reasonable extent?

The above data should be sent to William F. Jacob, chairman Library Census Committee, care of General Electric Co., Schenectady, N. Y., who will be glad to answer any question relating thereto.

California Institute of Technology

The California Institute of Technology is the new name for the larger institution developed from the Throop College of Technology at Pasadena. It has lately received $800,000 for general purposes and two endowments of $200,000 each for the support of research in physics and chemistry. In addition to this, $380,000 has been received for the construction of new buildings. An impressive architectural plan for the whole campus has been prepared by Dr. Bertram G. Goodhue, the well-known architect of New York and California.

The faculty has been strengthened in enviable measure. Dr. Arthur A. Noyes has resigned from the Massachusetts Institute of Technology and becomes director of chemical research. Dr. Robert A. Millikan of Chicago will spend one term each year and supervise research and instruction in physics. Dr. Albert A. Michelson (Nobel laureate), also of Chicago, will spend much time there engaged in research on the fundamental problem of earth tides, and Dr. Harry Bateman, formerly of Cambridge and Johns Hopkins Universities, is professor of aëronautical research and mathematical physics.

Special emphasis is placed upon the development at the Institute of the training of engineers of the creative or research type. To strengthen the courses in general culture, Alfred Noyes, the English poet, will give lectures on English literature and Paul Perigord has been appointed professor of economics.

Market for American Chemicals in Sweden

A material increase in the purchase of American drugs and chemicals in Sweden is reported by Walter H. Sholes, the American consul stationed at Gothenburg.

He reports that active introductory methods can stimulate greatly American business in that country.

Political and Commercial Control of the Nitrogen Resources of the World—II

A Description of the Commercial Aspects of Nitrogen Resources: Natural, Byproduct and Fixation Compounds, and of the Recent Developments and Changes in the Nitrogen Industry Practice*

By Chester G. Gilbert†

FREE nitrogen has no economic significance. To be available in the industrial arts it must be in a state of chemical combination. The form of compound is of secondary importance, since this may be modified more or less readily to suit the need, but its value is conditioned in terms of its availability in the form of nitrogen compounds. In consequence, the several sources are classifiable industrially under three heads:

1. Natural compounds—nitrogen occurring naturally in the form of marketable compounds.
2. Byproduct compounds—nitrogen rendered available incidentally in the course of operations otherwise directed.
3. Fixation compounds—nitrogen whose availability is dependent on special fixation treatment.

Natural Compounds

Chilean nitrate is the outstanding representative of this class. The guano industry, or what there is left of it, and a few other odds and ends of production from organic sources, belong here as well, but their combined output is relatively so small that the Chilean industry comprises what amounts to a monopoly of the natural resources. It is not operated as such, however, but by private capital, which owns and operates the oficinas, paying the Chilean Government a royalty or export tax amounting to about $11.20 per ton. British and Chilean interests share about equally in making up the far greater part of the capital invested. The balance is largely German and American. The total capitalization in 1909 amounted to approximately $134,000,000, representing an actual valuation of about $30,000,000. Various efforts on the part of the commercial interests involved to effect combinations for the purpose of stabilizing production have been attempted but have not been entirely successful, and the general tendency has all along been toward overproduction.

The operations, as already outlined on page 445, are crude and the cost of production is correspondingly high, amounting to around $25 to $30 per ton at seaboard, inclusive of the $11 export tax. The nitrate is marketed largely through commission houses. The American situation is mostly in the hands of three companies, W. R. Grace & Co., E. I. du Pont de Nemours & Co., and Wessel, Duval & Co. The magnitude of the Chilean industry as a whole and its relative importance are shown in Table I and Figs. 2, 3 and 4.[1]

Byproduct Compounds

To this class of compounds belong, with the few minor exceptions already noted, the nitrogenous products of organic derivation as a whole, and those from carboniferous sources, such as coal and oil shale. From the former source comes a miscellany of organic refuse resulting from activities dealing with animal, vegetable and fish products, and carrying nitrogen in the form of organic ammoniates commonly left as such for use in agriculture. From the latter the nitrogen recovered is all chemical nitrogen in the form of ammonia or ammonium salts, mostly ammonium sulphate.

Organic Nitrogen Supply

The organic production is impossible of definite analysis from any angle. The lack of systematically compiled records and back of that the miscellaneous largely decentralized character of the output, along with the fact that the producing costs are for the most part indistinguishable, leaves altogether too much to the imagination. Much of the supply is derived from connections of sanitation, especially of local sanitation, such as the rural practice, for which there is no measure whatever. Another prominent source of supply is represented in what is known as tankage, the refuse from animal-rendering plants; but here too the issue is lost in the scattering of the production, the indefiniteness of composition, and the fact that not all of the product is used as a source of nitrogen, some of it going into the preparation of animal food. The same is true of cottonseed meal and various other less prominent forms of organic waste resulting from industrial activities. Fish scrap and slaughter-house refuse from meat packing also contribute prominently and at the same time rather more definitely to the supply of agricultural nitrogen; but even here adequate figures are not available. The Federal Trade Commission undertook to analyze the 1913 consumption, with results given in Table II.

TABLE II—ESTIMATED CONSUMPTION OF NITROGEN IN COMMERCIAL FERTILIZERS FOR 1913

Materials	Fertilizing Substance	Tons Consumed	Content (per cent)	Units Consumed†
Nitrate of soda	Ammonia	260,000	18 0	4,680,000
Sulphate of ammonia	Ammonia	130,000	25.0	3,250,000
Cyanamide	Ammonia	15,488	18 0	278,784
High-grade tankage	Ammonia	210,000	10 5	2,205,000
Concentrated	Ammonia	18,351	14 5	266,090
Dried blood	Ammonia	40,000	17 0	680,000
Dried fish scrap	Ammonia	50,000	11.0	550,000
Cottonseed meal	Ammonia	660,000	7.5	4,950,000
Total				16,859,874

†A unit is 1 per cent of a ton, or 20 pounds.

This estimate, however, takes into account only the more strictly industrial sources, leaving rural sanitation and the like out of the reckoning.

The basis of this article by Mr. Gilbert was issued in mimeographed form for Government use as one of the Political and Commercial Geology Series prepared under the direction of J. E. Spurr, to whom book rights are reserved.

*For Part I see Chem. & Met. Eng., vol. 22, No. 10, March 10, 1920, p. 443.

†Curator of Mineral Technology, U. S. National Museum.

[1]See Chem. & Met. Eng., vol. 22, No. 10, 1920, pp. 444, 445, 446, 447.

Aside from the conversion of organic ammoniates, which is practiced on a large scale only in a few instances, notably that of the Paris system of sewage disposal, four general types of industrial operation figure more or less in the production of byproduct ammonia. They include coal distillation, bone carbonization, oil-shale distillation and blast-furnace operations. The American production, however, is all derived from the first two types. Both the others are active producers abroad, especially in Scotland, but neither of them has as yet obtained a foothold in this country. The American recovery in connection with bone carbonization is of minor consequence. Practically the whole supply comes from the gas works and byproduct coking operations. Fig. 3, in the shaded area designated "ammonium sulphate production," shows the magnitude and trend of the production from year to year since 1900.

Magnitude of Byproduct Nitrogen Compounds

The organic nitrogen recovered in all of the various byproduct connections taken together probably constitutes 40 to 50 per cent of the total supply. Coal product ammonia in this country adds another 12 to 15 per cent. So over half of our supply is of byproduct derivation. The domestic output is supplemented in the case of the organic form by considerable importations from South America, and as shown in Table I, until interfered with by the war, small amounts of ammonium sulphate were imported annually from Europe. Essentially, however, the byproduct supply is of domestic origin. Despite its magnitude, it occupies an anomalous sort of position industrially. It is recovered incidentally for what it is worth, and sold for what it will bring. The cost of production is largely charged off against the major operations with which its recovery is associated, and the returns are credited in conformance as a saving in the cost of the major operations. This is equally true whether the source be that of the domestic animal on the farm, a coke oven, or a packing house.

Controlling Factors in the Byproducts Nitrogen Supply

The industrial output is built up as a sequence to industrial concentration. This is evidenced all down the line, notably in the output of coke-oven ammonia from the steel industry and in that of organic ammoniates from the meat-packing industry. It is this influence of co-ordinated industrial concentration, along with the call for the major operations, that controls the supply of byproduct nitrogen; so the development and handling of the industrial output comes naturally to be largely in the hands of trade combinations. Thus, the coal product ammonia situation is largely at the disposal of The Barrett Co., the tankage and other animal product ammoniates gather for disposal at the hands of the packing interests, and the nitrogenous fertilizers from cottonseed are for the most part prepared and marketed by interests subsidiary to the Cotton Oil Co.

Byproduct Supply Is Not a Determining Factor in the Price of Nitrogen

The manufacturing interests involved are concerned primarily in the manufacture of other than nitrogen products. The byproduct nitrogen recovered has to compete for its market against what comes from the two other industrial classes of supply, and its price goes just low enough to enable it to do so. The limits set in the incidental character of the output leave no special incentive to carry the price competition further. Whatever additional latitude of advantage as to cost of production it possesses goes not to promoting a further reduction in the price of nitrogen but to lowering costs with reference to the major theme of production. Gas-house ammonia, for instance, does not affect the nitrogen market so much as it does the cost of gas, and the organic ammoniates recovered in connection with meat packing have not lowered fertilizer costs so much as they have kept down the cost of meat to the consumer. Thus, the byproduct class of supply, though the leading one in the point of magnitude and by far the cheapest to produce, has little to do with determining the price of nitrogen. The selling price of byproduct nitrogen is determined by the price the product from competing sources brings. In this country it is controlled by the price of Chilean nitrate, and not, as commonly imputed, by the trade combinations that develop and handle it.

Fixation Compounds

Nitrogen has five general habits of combination—that with oxygen, giving rise to nitric acid and its retinue of nitrate salts; that with hydrogen, giving ammonia and the ammonium salts; that with carbon, to form cyanogen and the cyanides; that with basic elements, yielding nitrides; and organically, in the form of organic ammoniates. Various projects have been advanced for turning these to account in the fixation of atmospheric nitrogen. For the most part they have met with little or no practical success, but there are exceptions to the rule of failure in all five directions.

Direct Oxidation—Arc Fixation

Nitrogen does not oxidize at all readily under any ordinary conditions, but its natural indisposition to combine with oxygen may be overcome by passing a mixture of the two gases through an electric arc. The atmosphere furnishes the nitrogen and oxygen ready mixed, so all that is needed in the way of raw materials is an abundant power supply. Arc fixation was developed in Norway, where the possibilities in the way of hydroelectric power give the best setting to be found anywhere in the world. Efforts to introduce it elsewhere have resulted unsatisfactorily, and arc fixation has made relatively little headway, as may be deduced from Table I and Figs. 2, 3 and 4. The reason is twofold. So far, its use of power has proved uneconomical and its product unsatisfactory. The former of these two objections depends for its force on the demand for power, but the latter is more decisive. The immediate end product is nitric acid, which is both difficult to transport and limited as to use. To be put in shape for agricultural use it must be neutralized in the form of a nitrate salt. Limestone is the only cheap neutralizing agent. This gives a salt, calcium nitrate, which absorbs moisture, cakes, and is thus unsuited to the American agricultural practice of machine drilling. An experimental plant near Seattle, Wash., aims to overcome this difficulty by turning out its arc product in the form of sodium nitrite, but the project is of no commercial significance as it stands at the present time.

Ammonia Fixation

Nitrogen is no more disposed to combine of its own accord with hydrogen to give ammonia than with oxygen to give nitric acid. In the case of the Haber process, the only synthetic ammonia process that has stood

the test of industrial application, the native indisposition to combine is overcome by subjecting a properly proportioned mixture of the two gases to heat and pressure in the presence of a catalyzer. This process was instituted in Germany shortly before the outbreak of the war, and as shown in Table I and Figs. 2, 3 and 4, has developed steadily since then. Little seems to be known as to the efficiency of the German Haber practice. Apparently careful manipulation is necessary to obtain results. This means skilled attention, which is incompatible with mechanical volume production and is thus unsuited to American practice. What aims to be an adaptation to American conditions was worked out by the General Chemical Co., and a plant with a rated capacity of 60,000 lb. of anhydrous ammonia per day was projected at Sheffield, Ala., at the instance of the Government. The plant was completed, but before it could be tuned up for actual production the war ended.

Cyanide Fixation

Nitrogen in passing through a red hot mixture of finely divided soda ash, coke and iron reacts with the sodium and carbon to give sodium cyanide. This principle of fixation is being extensively experimented with but has not been developed commercially, except in a small plant with a rated daily capacity of ten tons of sodium cyanide at Saltville, Va.

Cyanamide Fixation

Hot calcium carbide will absorb nitrogen, forming a compound of calcium, carbon and nitrogen, according to the formula $CaCN_2$, known as cyanamide. The cyanamide process, based on this reaction, has been extensively developed, far more so than any other of the various processes, as will be seen by referring to Table I and Fig. 2. Offhand, it looks to be the most adaptable and consequently the most promising of the lot commercially. In this connection, however, it is interesting to examine the several charts of its growth in the warring countries given in Fig. 2. In none of these is the showing indicative of a strong, healthy development. Worst of all is the case of Germany, with the contrast offered in the Haber and cyanamide charts. Until the war, cyanamide manufacture was unable to obtain a competitive foothold in the United States, although a small plant has been in operation at Niagara Falls in Canada for some years. The problem it has faced is similar to that already chronicled for arc fixation, in that it draws heavily on power in the preparation of the necessary carbide, and the cost of power in this country has been prohibitive. Under the stress of the war-time demand for nitrogen, however, the Government contracted for the erection of three plants—one at Muscle Shoals, Ala., one near Toledo, Ohio, and one near Cincinnati, Ohio—with a total rated capacity amounting to 220,000 tons of ammonium nitrate per year. The work on all three was well under way but none of the plants had reached the producing stage when the signing of the armistice brought the nitrate activities of the War Department to an end.

Nitride Fixation

The only process of any prominence aiming to fix nitrogen in the nitride form is one developed by the Aluminum Co. of America. This has for its working principle the fact that a mixture of alumina and carbon highly heated will absorb nitrogen by reacting to give aluminum nitride. The nitride when heated with caustic soda gives its end product in the form of pure ammonia. The outstanding difficulty encountered in applying this process commercially seems to be that of providing a furnace capable of standing the temperature requirements. At all events the process has not succeeded in making good industrially.

Bacterial Fixation

The artificial attempts at fixation have been directed almost wholly toward employing chemical principles. In view of the difficulties experienced and the uncertain value of the results as a whole, it is interesting and perhaps highly significant to reflect that after all, as indicated in Fig. 1, inorganic chemical principles seemingly have little to do with developing the natural supply, probably because of the activities of nitrifying bacteria. Little attention has been given to the possibilities in this direction. This is only natural so far as commercially actuated research is concerned, since it does not lead in the definite direction of patent rights; but the failure to institute an adequate investigation governmentally can be attributed only to lack of comprehension with reference to the scope of the nitrogen issue as brought out on pages 446 and 447. The subject has received just enough attention to show that bacterial fixation represents a tremendous field of grossly neglected possibilities.

Recent Developments and Changes in Practice

The whole matter of fixation must be regarded as in process of development. True, it was instituted about fifteen or twenty years ago and has grown to represent the largest producing source of chemical nitrogen with operations in practically all the important industrial countries in the world and with responsible financial backing. But no one can examine the charts in Fig. 2 without recognizing the premature mushroom quality of the upgrowth, induced primarily in response to the political conditions leading to and through the war. This is especially true for the American situation. When the war broke out, fixation here was confessedly still in the dependent stage of its development, unable in every effort it had made to stand alone industrially. In the main, the developments that have transpired subsequently have followed along pre-existing lines. In so far as they have done so, little actual economic significance is to be attached to them. For the rest, the new developments, all that can be said at this juncture is that they are disappointingly meager.

Military and Agricultural Nitrogen Fixation Procedure

Just one war-time achievement, the oxidation of ammonia, stands out as affording a worth that is unmistakably clear. The nitrogen situation, it will be recalled, has two aspects, the military and the agricultural. The military focus is on nitric acid and the readiest means of insuring a supply; the agricultural focus is on ammonium compounds or their equivalent in neutral nitrogen salts and the most economical means of supply. Here, then, is a parting of the ways to expediency, and it is at this juncture that with military influences to the fore the nitrogen developments of the past few years were led off on an uneconomical tangent of military control. The Bureau of Mines, however, taking up the work of others, has perfected a simple, effective means for oxidizing ammonia to nitric acid. This, beyond question, is the most important contribution of the day.

Its significance may perhaps best be brought out graphically as in the accompanying Fig. 5.

Advantages of Agricultural Nitrogen Fixation Procedure

Ammonia oxidation, it will be observed from Fig. 5, gives a means of supplying the military requirement from the direct line of agricultural efficiency. From the strictly military viewpoint, it has the objection of being a roundabout procedure. The dotted line of direct military procedure, however, has no peace-time function, and consequently cannot be maintained in time of peace in

FIG. 5. MILITARY AND AGRICULTURAL NITROGEN FIXATION PROCEDURE

trim for war, but must instead be built up expressly to meet war-time exigencies. We have had an illustration of what this means in the way of time and money, and this one ought to suffice. The agricultural channel once built up on a basis of economic efficiency is open at all times. At the most, all that is required is to keep an eye to the emergency needs in the way of oxidation equipment, a relatively simple matter. Thus, instead of the precarious procedure of trusting to luck which characterized our pre-war attitude toward nitrogen on the one hand or of attempting the impossible in the way of maintaining a military program of industrial procedure in time of peace on the other, all that is needed is a constructive program devoted expressly to the interests of economic efficiency.

(*Part III, dealing with the nitrogen outlook and a bibliography on the general subjects of the nitrogen industry, will be published in our next issue.*)

Mineral Oil as a Factor in United States Trade

MINERAL oil has been a factor in the foreign commerce of the United States since 1862, when the first statistical record of imports and exports of this commodity appears. So rapid has been the growth of this trade that in the fiscal year ended June 30, 1919, mineral oil ranked first in order in magnitude of quantity in imports and second in exports. Its comparatively low value, however, places it fifth in value of exports and far down the list in value of imports. In 1862 exports of mineral oil, both crude and refined, were 5,829,929 gal., valued at $1,539,027. Fifty-five years later, in 1917, these exports reached the peak, aggregating 2,748,328,485 gal., valued at $230,968,940, but fell in 1919 to 2,529,064,893 gal., valued at $344,233,216, a decrease of 8 per cent in the quantity but an increase of 49 per cent in the value.

Despite the fact that the United States is the world's largest producer and exporter of mineral oils, imports have grown from a total of only 211 gal., valued at $141, in 1862 to the enormous amount of 1,978,951,092 gal., valued at $28,612,799, in 1919. When compared with 1914, the last pre-war year, this is an increase of 150.1 per cent in the quantity and of 109.4 per cent in the value.

The oil industry was begun in America in 1859, in which year the production of crude petroleum in the United States was estimated at 2,000 bbl. So rapidly did the industry grow that in 1860 production rose to 500,000 bbl., and it has climbed steadily since to the high record of 350,131,000 bbl. for the calendar year 1918. The output of the United States from 1859 to 1918, inclusive, makes a grand total of 4,602,775,000 bbl. of 42 gal.

A total production of 350,131,000 bbl., valued at $690,190,000, in 1918 places petroleum third in the value of mineral products of the United States. Bituminous coal led, with a production valued at $1,465,000,000, and pig iron was next, valued at $1,180,759,565.

Despite the fact that the production of mineral oil has increased from a little less than 266,000,000 bbl. in 1914 to more than 350,000,000 bbl. in 1918 (production figures are for calendar years), imports of mineral oils have increased steadily, reaching a total of 1,978,951,092 gal., valued at $28,612,799, in the fiscal year ended June 30, 1919, against 791,137,399 gal., valued at $13,665,940, in 1914 and 1,403,727,624 gal., valued at $21,926,370, in 1918. This is an increase of 575,000,000 gal. in 1919 over 1918. These imports are mostly crude oil and come chiefly from Mexico, with comparatively small quantities from Peru and Trinidad, all of which arrives by tank steamers. With the single exception of 45 gal. in 1916, no oil from Mexico was entered across the Mexican border during the past six years.

Exports and Prices of Mineral Oils

Although imports are mostly crude oil, more than 90 per cent of the exports of mineral oil goes out in the refined form. There has been a gradual decline in the quantity since 1917, despite which the value, reflecting the advance in price, registered an increase of more than $113,000,000 in 1919 over 1917, and the total valuation of $344,233,216 breaks all previous records. When compared with 1914 figures, exports of mineral oils show an increase of only 10.8 per cent in the quantity but an increase of 126.2 per cent in the value.

Exports of mineral oils in the fiscal year ended June 30, 1919, comprised 163,782,498 gal. of crude mineral oil, valued at $9,905,490; 898,044,039 gal. of fuel and gas oil, $49,918,288; 725,686,746 gal. of illuminating oil, $81,495,706; 273,148,541 gal. of lubricating oil, valued at $86,156,695, including 7,596,525 gal. of paraffine oil, valued at $1,173,821; 322,920,087 gal. of gasoline, $78,088,061; 145,301,861 gal. of all naphthas and other light products of distillation, $38,654,419; and 181,121 gal. of residuum, $14,557; making a grand total of 2,529,064,893 gal., valued at $344,233,216.

The average import price of crude mineral oil was 1.5c. per gal. in 1914, but fell to 1.25c. in 1919. The average export prices per gal. of the various mineral oils were as follows: Mineral oil, crude, 4.7c. in 1914 and 6c. in 1919; fuel and gas oil, 2.9c. in 1914 and 5.6c. in 1919; illuminating oil, 6.4c. in 1914 and 11.2c. in 1919; lubricating oil, 14.1c. in 1914 and 31.5c. in 1919; gasoline, 14.3c. in 1914 and 24.2c. in 1919; all other naphthas, an average of 13.8c. in 1914 and 26.6c. in 1919. All export prices show substantial increases, but the price of lubricating oil shows the heaviest advance, having more than doubled since 1914.

The Nature of the Defects Revealed by the Deep Etching of Transversely Fissured Rails*

Microscopic Studies Which Show That the "Gashes" Developed by Deep Etching of Polished Surfaces Correspond to Tightly Closed Intracrystalline Cracks — They May Be Discovered by Dipping a Magnetized Specimen Into a Suspension of Fine Iron Dust

By HENRY S. RAWDON†

THE importance of deep etching by means of concentrated acid in the study of rails showing the defects of transverse fissures has been definitely established.[1, 2] The real nature of the defects revealed has never been demonstrated with certainty, however, and in consequence various views are held as to the interpretation and value of the indications of the deep-etching test. In the different conflicting opinions expressed, the "defects" revealed in rails of this type have been attributed to possible variations in the rate of solubility of the steel in different directions, to internal stresses within the material, and to pre-existing discontinuities or separations within the metal. All of the previous investigators of this subject agree, however, that the defects are of such a nature that ordinary metallographic methods do not reveal their presence. As part of the study of railway materials authorized by Congress by special appropriation for the purpose, the Bureau of Standards has been engaged for some years in the investigation of defective rails, particular attention being paid to those showing transverse fissures. The urgent need of determining the nature of the defects in rails of this type which are revealed by deep etching has recently directed the course this investigation has followed.

FIG. 1. DEFECTS REVEALED IN TRANSVERSELY FISSURED RAILS BY DEEP ETCHING

Longitudinal section of rail No. 3 (Table I) parallel to the tread. The surface was deeply etched with hot concentrated hydrochloric acid. × 1.

As material for study, three rails which had been removed from the track because of the presence of transverse fissures were used. The three differed markedly in composition, as shown by the data summarized in Table I:

TABLE I. COMPOSITION OF RAILS USED

Rail No.	Carbon, per Cent	Manganese, per Cent	Phosphorus, per Cent	Sulphur, per Cent	Silicon, per Cent	Chromium, per Cent	Nickel, per Cent
1	0.63	0.71	0.014	0.022	0.09	0.50	1.89
2	0.62	0.91	0.020	0.036	0.01	Not detected	Not detected
3	0.90	1.22	0.094	0.022	0.14	Not detected	Not detected

Sections of the head of each of the three rails were cut parallel to the tread into a series of slices approximately ¼ in. in thickness. Each of these slices, after

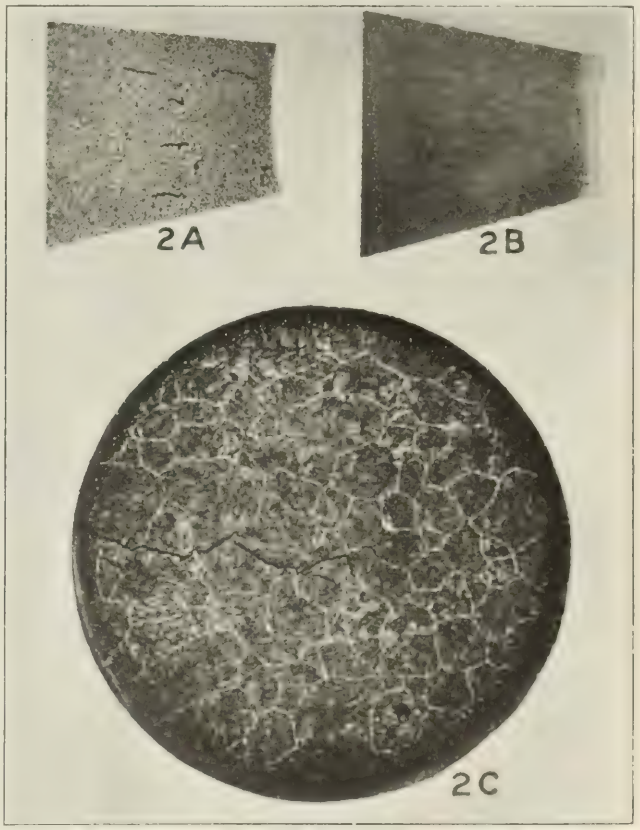

FIG. 2 DEFECTS IN GUN FORGINGS REVEALED BY DEEP ETCHING

A. Transverse radial section from a forging for a gun tube deeply etched with concentrated hydrochloric acid. × 1.

B. Same specimen as *"A"* after polishing, but before etching. The defects revealed in *"A"* are readily visible before the specimen is etched. × 1.

C. Cross-section of a 1-in. "round" trepanned out of a large bloom intended for a gun tube; etched with 2 per cent alcoholic nitric acid. The crack, which is, undoubtedly, of the same origin as the defects in *"A"* and *"B,"* probably originated at a rather high temperature. It is largely intercrystalline in its course. × 3.

*Report No. 85 to Rail Committee, Am. Ry. Engrg. Assn.

†Associate Physicist, Bureau of Standards.

[2]M. H. Wickhorst, "Transverse Fissure Rails on Atchison, Topeka & Santa Fé Railroad, Heat 41,177," Bulletin 218, Am. Ry. Engrg. Assn. August, 1919, p. 1.

grinding, was etched with hot hydrochloric acid (sp.gr. 1.19), to determine whether the defects noted by previous investigators were present or not. In each rail they were found in abundance in the central and the lower portions of the head. Fig. 1 shows a longitudinal section, parallel to the tread, cut from the lower portion of the head of rail No. 3 which has been deeply etched.

Defects similar in appearance to those seen in the etched rail sections have been noted in defective ingots and blooms of gun steel. Fig. 2a shows the defects in such material. That these defects are initially present in the material is evident from Fig. 2b, which shows the same material before etching. The nature of these

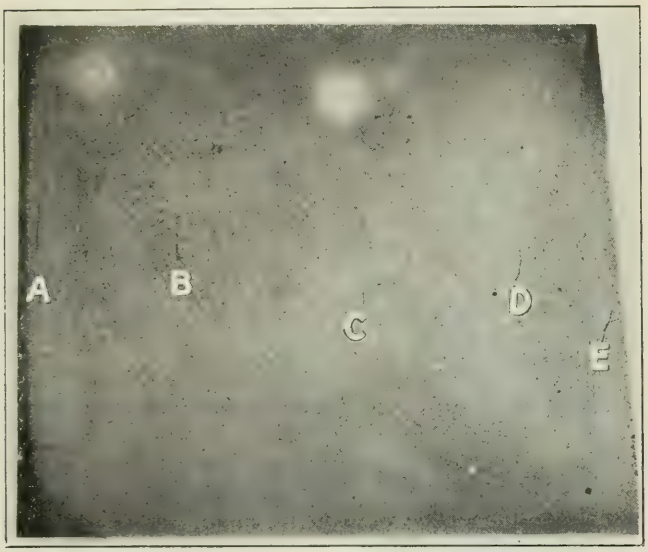

FIG. 3. DEFECTS IN TRANSVERSELY FISSURED RAILS

The specimen of Fig. 1 after polishing, but before etching, was magnetized and then immersed in a suspension of fine iron dust in kerosene. (Compare with Fig. 1.) × 1.

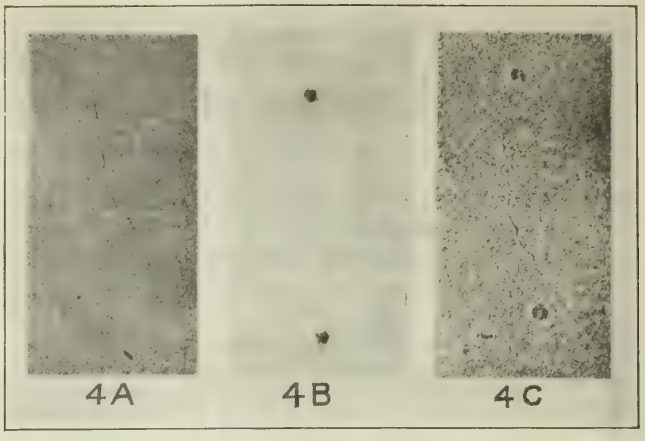

FIG. 4. INTERIOR CRACKS EXISTING IN TRANSVERSELY FISSURED RAILS

A. Crack *"B"* of Fig. 3 viewed obliquely. × 3.
B. Same specimen as *"A"*; the line of the crack shown in *"A"* was located by a punch mark at each end of the crack and the iron dust was wiped off. No crack is visible. × 3.
C. Same specimen as *"B,"* treated a second time with iron dust. (Compare with *"A."*) × 3.

"cracks" or separations is illustrated by Fig. 2c, which shows a section of a 1-in. "round" trepanned out of a defective bloom of gun steel. The defects are of the nature of cracks largely intercrystalline in their course —i.e., they extend between the grains, for the most part, rather than across them.

It might naturally be expected that the defects revealed in the rails are of the same character as those shown above in the gun steel. It is extremely difficult, however, to demonstrate the presence of any features in the unetched material corresponding to those found in the deeply etched specimen. As already stated, the usual metallographic methods are ineffective; various other means were tried, including examination by means of X-rays. Radiographic examination even of sections

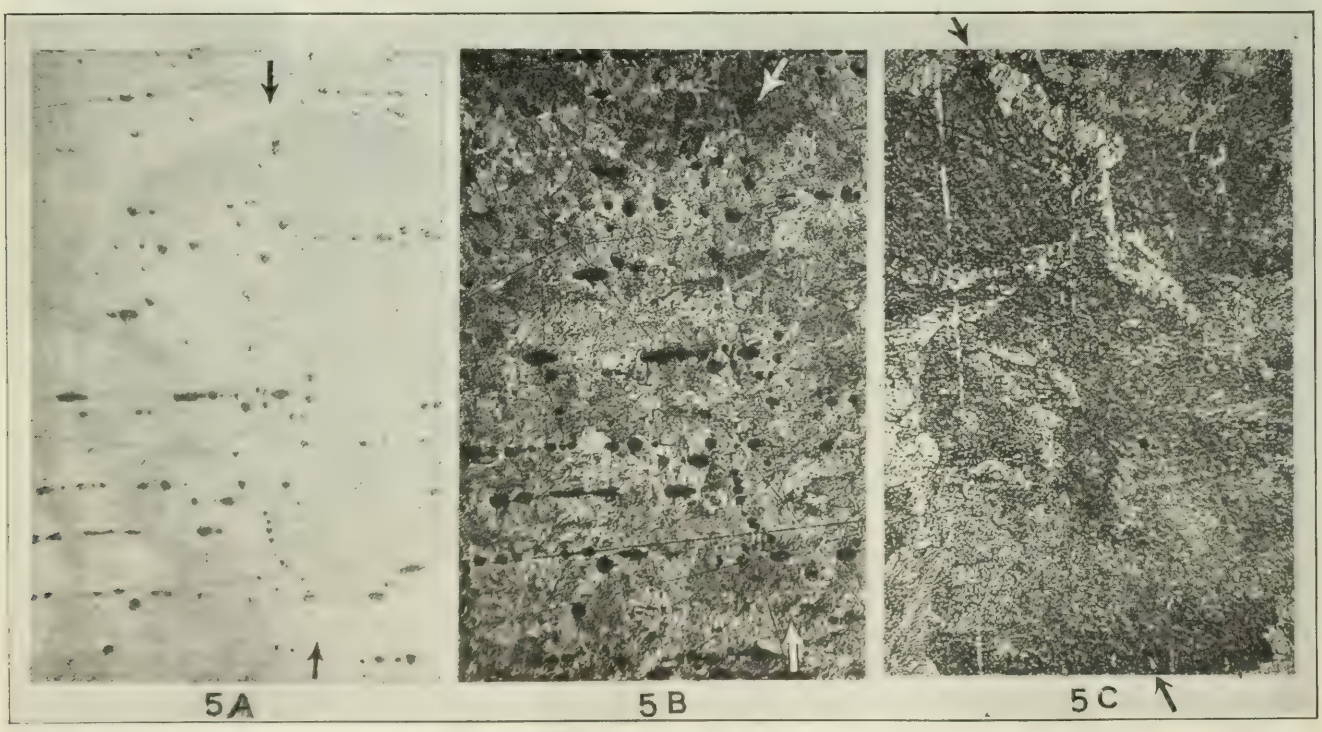

FIG. 5. MICROSCOPIC APPEARANCE OF CRACKS EXISTING IN TRANSVERSELY FISSURED RAILS

A. Crack *"B"* of Fig. 4; specimen is unetched. × 50.
B. Same specimen as *"A,"* etched with 2 per cent alcoholic nitric acid. The metal is in such intimate contact along the line of the defect that only a very faint indication of its presence could be obtained. × 50.
C. Same specimen as *"B."* × 500. Even at this magnification the course of the crack (indicated by arrows) is relatively very inconspicuous.

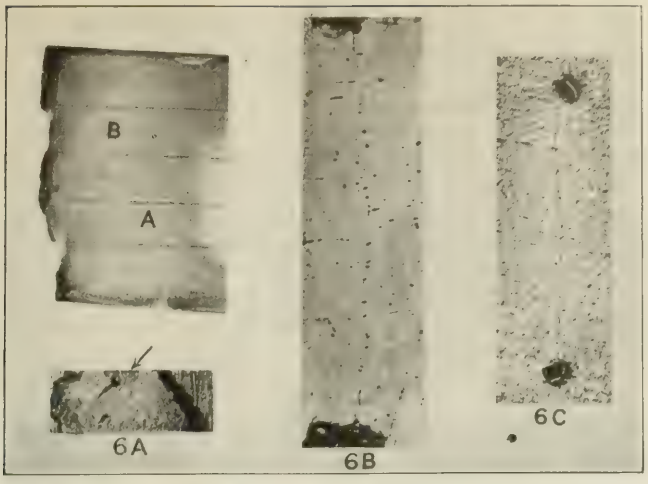

FIG. 6. NATURE OF THE INTERIOR DEFECTS REVEALED BY THE DEEP ETCHING OF RAILS CONTAINING TRANSVERSE FISSURES

Upper left—Longitudinal section of rail No. 1 (Table I) parallel to the tread. The two defects *"A"* and *"B"* were located by the magnetic method.

A. Fracture of the strip of specimen containing defect *"A."* The rail section was cut into strips as shown and fractured by a transverse break, along the line of the defect. The semi-circular area, indicated by the arrow, corresponds to the defect.

B. Defect *"A."* By means of a punch mark at each end, the crack has been opened; specimen is unetched. × 50.

C. Defect *"B."* The crack has been opened by means of punch marks as shown. Specimen was slightly etched with 2 per cent alcoholic nitric acid. × 10.

no more than ¼ in. in thickness did not reveal the presence of any unusual features.

The only method by which the defects can be located without etching the material is a magnetic one. The specimen, which must be well polished on the surface as for microscopic examinations, is magnetized and then immersed in kerosene or a similar liquid, containing very fine iron dust in suspension. "Cast-iron mud" from disks used for lapping operations is admirable for the purpose. Particles of the iron dust collect upon the polished face of the magnetized specimen and at the places where, because of a discontinuity within the metal, a change in the density of the magnetic flux occurs, orient themselves to correspond to the shape of the discontinuity. The specimens are finally washed in clean kerosene to remove as much as possible of the excess iron dust which is scattered over the surface.[3]

In Fig. 3 is shown the appearance of the specimen illustrated by Fig. 1, before etching.

It was given the treatment outlined above. It is extremely difficult to photograph the surface so as to show clearly the results of the treatment with iron dust. They are readily seen upon visual examination, much more so than might be inferred from the photograph. Comparison of Fig. 3 with Fig. 1, however, shows a very fine "crack" or discontinuity in the unetched sample corresponding to each of the defects found in the specimen after deep etching.

The appearance of the cracks located by the magnetic method is more clearly shown in Fig. 4, somewhat magnified, in which the surface was viewed obliquely. Crack *"B"* (Fig. 3) was located by means of iron dust after magnetizing the specimen. Its position was then recorded by a punch mark at each end of the crack. Fig. 4b shows the specimen after the iron dust was wiped off; no crack can be detected between the two punch marks. In Fig. 4c the same area is shown after a treatment with the iron dust. Although it is known with certainty that a discontinuity exists in the steel between the two punch marks, it is extremely difficult to find evidence of it in the microstructure even after

[3]This method was developed at the Bureau of Standards under the direction of Major W. E. Hoke for the inspection of precision length gages.

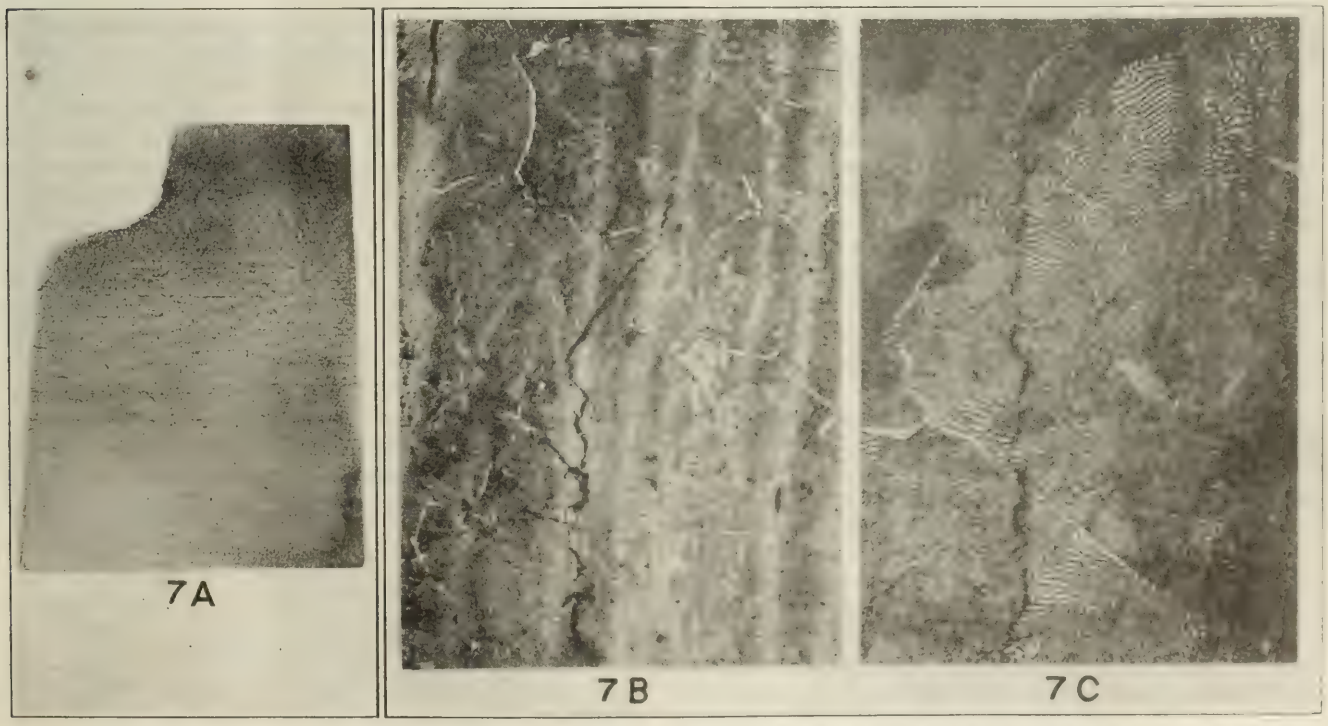

FIG. 7. MICROSCOPIC NATURE OF THE INTERIOR DEFECTS FOUND IN RAILS OF THE TRANSVERSE FISSURE TYPE

A. Longitudinal section of rail No. 2 (Table I), parallel to the tread, showing the interior cracks as they appear after slight etching with concentrated hydrochloric acid. × 1.

B. Specimen *"A"* after slight etching in concentrated hydrochloric acid to widen the crack, repolished and etched for microscopic examination. The crack is intracrystalline in its course. There is some evidence of banding due to phosphorus. Etched with 2 per cent alcoholic nitric acid. × 100.

C. Same material as *"B."* The intracrystalline nature of the crack is very evident. Etched with 2 per cent alcoholic nitric acid. × 500.

light etching. In Fig. 5 is shown the best indication found of the presence of such a crack in the area between the two punch marks. This is very faint, however, and would be regarded in the ordinary microscopic examination as of little or no significance. The faces on the opposite sides of the discontinuity or fissure are in such intimate contact that at a magnification as high as 500 diameters the course of the crack is relatively very inconspicuous, as is shown in Fig. 5c. The course of the crack which has been indicated by arrows is hardly more conspicuous than the dark boundaries of the pearlite masses which constitute the structure of the steel. The failure of the radiographic examination to reveal these defects is due to the intimate contact between the two faces of the crack; the specimen behaves as solid metal does for this reason.

In Fig. 6 is shown a slice cut from the head of rail No. 1, parallel to the tread, in which two defects have been located by means of iron dust after magnetization of the specimen. By means of punch marks close to the ends of the cracks, it was found possible to open the fissure, as is shown in Figs. 6b and 6c. The slice containing the defects was then cut, as shown by the ruled lines, and each strip broken transversely along the line of the defect. The break was localized by means of a slight sawcut on each side in line with the crack. The appearance of the fracture is shown in Fig. 6a. A definite area which is easily distinguished from the surrounding sound material corresponds to the defect previously located. The strip containing crack *"B"* showed a similar characteristic spot when broken. The area, semi-circular in Fig. 6a, is identical in appearance with the nucleus of transverse fissures and with the "gray spots" often revealed in the transverse breaks of the heads of defective rails of this kind.

The nature of these defects can best be studied in material in which the carbon content is low enough so that the grain boundaries are clearly outlined by ferrite envelopes. Rail No. 2 was found to be very suitable for this purpose. Fig. 7 shows a section of this rail after slight etching with concentrated hydrochloric acid. The interior cracks having been widened by the concentrated acid, the surface was ground down, repolished and re-etched for microscopic examination. In Figs. 7a and 7b a crack is shown passing through the grains and across the grain boundaries. The cracks are intracrystalline in their course—i.e., the break has occurred through the grains rather than between them.

Results of the Examinations

The results of the examination given above definitely warrant the conclusion that the defects ("gashes," "fissures" or "cracks") revealed in rails of the transverse fissure type by means of deep etching exist within the material previously to the etching, as discontinuities within the steel. The function of the acid used for etching is merely to widen and deepen the *pre-existing* cracks. The microscopic appearance of these cracks offers some suggestions as to their origin. The course of the crack is intracrystalline and has the general appearance of a fracture produced in normal material; there is no evidence of inherent weakness at the grain boundaries. An answer to the question as to whether the separation occurred while the metal was cold (i.e., in the track), or while hot (i.e., in the mill), does not appear to be forthcoming from the evidence offered by the examination of the fractures alone. No definite statement can be made on this point. However, the comparison of internal fractures found in ingots and blooms and hence, in all probability, produced at a rather high temperature (Fig. 2) with those found in rails which were removed from service because of transverse fissures (Fig. 7) is very suggestive.

The internal cracks shown in Fig. 2 are of the intercrystalline type. In general, this is a characteristic of fracture produced in metals at elevated temperatures. On the other hand, the cracks shown in Fig. 7c are of the intracrystalline type, a feature which, in general, is characteristic of fractures produced in metals broken at ordinary temperatures.

Summary

1. It has been definitely shown that the defects found in transversely fissured rails in abundance after deep etching exist within the metal initially—i.e., before etching. The concentrated acid merely widens and deepens these defects.

2. These defects are internal fractures, roughly circular in area, and are of the intracrystalline type of break; otherwise, the metal appears sound.

3. These defects may be revealed with certainty before etching by magnetizing the polished specimen and then immersing it in a suspension of very fine iron dust in kerosene or a similar liquid. This method appears to be the only one for determining the presence of these and similar defects with certainty without etching the piece and thus destroying the characteristic features of the defects.

Touring Exhibition for British Industry

In the interests of British commerce in overseas markets the Department of Overseas Trade is completing arrangements for a comprehensive touring exhibition with the object of showing to advantage the manufactured products of the United Kingdom.

For a start the itinerary comprises South Africa, Australia, New Zealand and Canada. The duration of the tour will be about eighteen months, and, should the venture be attended with the degree of success which is anticipated for it, similar projects to other parts of the world will receive consideration. Matters are rapidly taking shape, and in a comparatively short space of time full details of the scheme will be submitted to the manufacturers of the country. It is intended that about 500 firms shall be invited to take part in the tour, and considerable support has already been forthcoming. Only British firms may participate.

In addition to showing the goods, the question of selling them has received attention. It is hoped to work in with the staff arrangements an agency in which orders can be taken and transmitted to the manufacturer.

Chemists' Club Will Purchase German Marks

The depreciation in German marks has been a matter of misfortune to some people in this country who have had considerable sums of German money. The Chemists' Club has recently announced through its Secretary, J. R. M. Klotz, 120 Broadway, New York City, that anyone who desires to dispose of marks at the price originally paid can do so through a plan which has been devised by the Club. Parties interested should communicate with Mr. Klotz.

Need of Co-operative Educational Work in the Chemical Industry

A Plea for Co-operative National Education in the Uses of Chlorine in Our Daily Life and Examples of the Beneficial Results Already Obtained by Co-operative Propaganda in Many Other Fields of Manufactured Products

By JACOB G. COHEN

IN HIS work on Municipal Chemistry Prof. Baskerville showed, several years ago, the value that minute quantities of chlorine would have if added to the water with which streets are flushed. It has been urged by Albert H. Hooker in his work on Chloride of Lime and Sanitation. Here we have the greatest disinfectant known to man, at once cheap and available. And we have in the dust of our streets the bacilli of tuberculosis, tetanus, influenza and the germs that are said to be active in spreading coughs and colds, besides a lot more of the kind.

The Hazen theorem indicates that when an impure water supply in a community has been removed through the use of chlorine, the general death rate is reduced. It has been shown, where such change took place, that for every person thus saved from typhoid fever, three other persons are saved from death due to other causes usually not considered influenced by the character of the water supply. Infantile mortality caused by bronchitis, tuberculosis, pneumonia and other disturbances indicate a lowered vital resistance from the drinking of polluted water. An improved water supply forecasts increased health of the people of the community, a real tangible building up of bodily resistance to germ disease. Says George W. Fuller:

"Many sanitarians and medical men are clamoring stoutly for the elimination of all sewage matters from American streams. Literally this is impossible. No longer can there be streams of pristine purity in populous districts. This is one of the penalties of civilization.

"On the other hand, it may be freely stated that many streams are now polluted to a disgraceful degree. Corrections are most urgently needed.

"Fortunately there is now available by the hypochlorite method a reliable means of sterilizing or disinfecting sewage or water at a small cost. The full significance of this is not yet fully appreciated. It has much bearing on the question of sewage disposal in general, and in the duration method in particular, as related to some conditions."

Chlorine's Place in Our Daily Life

Chlorine on the farm for water and sewage infection, chlorine to banish the house-fly and the many diseases that follow in its trail, chlorine for prevention of epidemics, and use in surgery and general sanitation, it ever comes in our daily life, affairs and contacts. When the full realization of its value to all humanity comes, then will its uses become more general and its production become greater.

"We are searching for an outlet for our excess chlorine in metallurgy and in organic chemicals. If our electrolytic chlorine friends would begin telling people how they can live in a prophylactic environment, how they can feed their babies pure milk, and how they can avoid poisoning their neighbors who live lower down on the same watershed, conditions in the chlorine market would soon be such that they would no longer worry about what the Government is going to do with Edgewood."

This quotation from a paper on "Chemistry in Its Human Relations" read at a meeting in Buffalo indicates an essential need in the alkali industry. Increased number of buildings, increased surplus of elemental and manufactured materials, and a market that is glutted and sluggish from the standpoint of turnover mean that the chlorine people can take a leaf from the history and experiences of other industries that had the same situation to overcome. How they did it in a co-operative way will be briefly told in this paper, while the application of the principles to the problem of chlorine and its products will be but touched upon.

Individual vs. Mutual Interest

In the early period of American manufacture, individualism was suited to this growing stage. But the days are over when manufacturers considered that competition meant keeping to themselves everything they learned and going on their own individual paths into the markets of the country and the world. There was no regard for honorable tactics when competition was concerned, but business today has passed this stage; and for today and tomorrow and the tomorrows to come, it must be considered in its larger, greater, common grounds of mutual interest.

Industry can succeed best in this world when it renders real service, and in this opportunity for serving there will always remain individual initiative in matters of practice and competition in matters of effectiveness. This is done through the right kind of working co-operation, one which benefits the public at large by research work in facts and information gathered, and by giving the public the realization of its value through recognized media of publicity. Supplementing this general work of developmental co-operation comes creation of a code of ethics in competition, a standardization of specifications and practices in the engineering and sales management of the various companies of the industry considered with respect to the relations of any one manufacturer to all in that particular industry.

The day of organization is here, emphasized in such singularly effective manner during the period of the war—in one great industry after another the spirit of internal competition is yielding to co-operation within the ranks.

Decidedly, a condition exists in the alkali industry

which makes necessary a widening of the market. This cannot be done by one member taking away the market of another. It can be done only by a broad, effective effort to sell the American people on the uses of chlorine products, to sell more by educational efforts and thus make a better market for all. The increased volume of business will repay the small sum any one manufacturer will contribute toward such a campaign of co-operative national education.

Co-operative Advertising in the Building Materials Field

That this theoretical advantage of co-operative national education has proved successfully practical is attested by the fact that during recent years scores of industries in this country have organized for the joint promotion of their products. A glance through the leading journals shows the wide diversity and range of industries that are using this form of educational propaganda to increase the use of their product.

The Lumber Industry

The story of co-operative advertising in the lumber industry is one of continuous success. The Southern Cypress Manufacturers Association was one of the first in the field. Its annual appropriation for this purpose has been materially increased each year. In a letter from the secretary of that association, dated Sept. 27, 1917, he advises that its total revenue for promotion work during the fiscal year ended June 30, 1917, was approximately $140,000. He makes this significant statement:

"Our subscribers, or members, have felt a most decided improvement in business conditions as a result of our advertising. Cypress stands out alone of all woods as being in the most prosperous condition. During the first half of the present year, the manufacturers of all other woods suffered a decline in prices and curtailed their production."

Common Brick Manufacturers

Another association of manufacturers in the building field is that which has grown out of the demands created by the war, called the Common Brick Manufacturers Association of America. The common brick manufacturers have been asleep while the lumbermen, face brick manufacturers, the cement industry and the makers of hollow tile went after increased trade and secured it. The lumbermen went after the building business. They worked with the architect, the engineer and the contractor. They furnished plans free and even helped finance buildings. So well did the lumbermen succeed with their propaganda work that today it is estimated that fully 85 per cent of all the materials used for buildings erected in the United States was sold by the lumber dealers.

To correct this condition is the object of the plans of this co-operative association. Their work will consist of paid publicity in all of the large journals, publications, and books showing the use of brick in chimneys, garden fences and other ornamental features. It will teach the common carpenter and small contractor how to build and figure a brick house. It will prepare books and publications; it will treat the proposition of building with brick in an A B C way. The big talking point is in the fact that the price of brick has increased relatively less than that of any other building material. The brick manufacturers realize their opportunity at this time, in the fact that a brick house costs just about the same as one made of lumber and lasts a good deal longer. The association plans to follow up this opportunity in a constructive and progressive manner.

White Pine Bureau

The White Pine Bureau, composed of white pine manufacturers in the Northwest, has a large annual appropriation that it devotes to propagating the use of white pine in the building of homes. Through this campaign they have discovered the public and realized that it is the selfsame public and not the dealer or broker that is the turning factor in their interest. Their present campaign was planned for a 5-yr. period. It has been in operation so far for only three years and despite the conditions brought on during the war period they feel that their efforts were well worth while. Results of their educational work are beginning to show themselves now through increased use of their materials, and they have the satisfaction of securing wholehearted and enthusiastic co-operation from their dealers as a result of this campaign, as well as developing a new public to the use of the particular forms of building material that they manufacture.

Paint Manufacturers

The Paint Manufacturers Association of America, under the direction of its educational bureau, has completed its plans and is now at the beginning of a 5-yr. "Save the Surface" campaign which will represent a total investment of $625,000. This educational work will be carried out in the interest of all the branches of the paint and varnish industry in a purely impartial manner and no particular material will be favored or particularly recommended at any time during this campaign. The entire object is to bring home the realization that a greater use of paint materials lengthens the life of the object on which this material is used; that in saving the surface many years are added to the life and wear of the object to which it is applied. It is purely propaganda for education, and as the realization comes of the true value of paint materials, a benefit to those who have contributed to this fund will come in the increased use of their manufacture.

Portland Cement Association

Unlike the Common Brick Manufacturers Association the Portland Cement Association has been a constant user and believer of all forms of educational publicity for a good many years. This work has had much to do with the notable growth and advance of the cement industry. As indicative of the association's belief in the success of its work, its appropriation for 1917 was three times as great as the fund that was devoted to it the year previous, and that amount had increased over that of the preceding year.

Magneto Manufacturers Active

Five important manufacturers of magnetos are united to win back the market for their product. Prior to 1911 practically every automobile was equipped with magneto ignition; but due to a variety of causes the percentage of passenger machines thus equipped dropped to 18 per cent in 1918. The reason for this slump is attributed to the strong publicity for battery ignition as well as to the neglect of the magneto manufacturers

properly to acquaint the public with the merits of their product. This work, as educational work, is supplementary to the competitive publicity used by these different manufacturers in their individual campaigns.

Co-operative Association Brands

The advertisers of fruits, nuts and raisins, especially those situated on the Pacific Coast section of this country, have been regular and persistent developers of the general public opinion. Almost any national publication contains in its advertising section advertised fruits of the California Fruit Growers Association, "Sunkist," California Associated Raisin Co., "Sunmaid," Yakima Valley Fruit Growers Association, "Big Y," the Northwestern Fruit Exchange, "Skookum," California Walnut Growers Association, "Diamond Brand," Florida Citrus Exchange, "Sealdsweet."

Oregon Prune Growers

Even the humble prune will soon enter the market through being standardized, trade marked and advertised. The causes which led up to this action on the part of the Oregon prune growers are due to the ever-increasing production of the present bearing acreage, the realization and necessity for a standard product, the creation of markets to care for future surplus, the enormous prices and potential crop of California prunes which dominates the field, and the seemingly unnecessary price fluctuations. The problem, therefore, is what to do with this enormous increased production; how to find new markets; how to create a greater demand; and, of paramount importance, how to maintain prices on a stable "cost of production price" basis for every brand of prune there is. To secure these results it has been planned to spend over $200,000 within the next twelve months to acquaint the general public with its graded and branded prune.

American Cranberry Exchange

The American Cranberry Exchange is a co-operative organization of cranberry growers supported by assessments levied upon its members, which include the leading growers of fruit. It controls distribution and has created an artificial demand for cranberries, that is, created a demand other than that created by the age-old custom of serving cranberry sauce with the turkey on Thanksgiving. In this connection it is interesting to know that the general manager of the exchange in his annual report said: "With an adequate amount of publicity an artificial demand can be created sufficient to consume the largest possible crop." This is especially interesting because before the advent of any national cranberry advertising the growers experienced a number of bad years when the crop was heavy and the demand was light.

Laundry Machinery

Appreciating the fact that its success is bound up with the industry it serves, the American Laundry Machinery Co. has launched a campaign which it expects to conduct over a period of at least three years to inform the housewives of America, as simply and pleasantly as it may, the advantages of modern laundry methods over the old-time washboards and the mess and worry of wash day. The campaign also contemplates a hard and continuous drive to protect the industry and to protect as far as possible the further inroads of manufacturers of home power laundry equipment by getting before the housewives the laundries' side of the story. The campaign which has been worked out for developing a legitimate market open to the industry is largely educational. An analysis of the potential market leads the company to believe that fully one-half, or 10,000,000, of the homes in the United States can be considered as possible patrons of the laundries. Estimated surveys show that if each of these homes were to send a bundle of home work each week amounting to $2 (which is low), it would mean a total volume for the laundries each year of $1,040,000,000.

Automotive Wood Wheel Makers

The Automotive Wood Wheel Manufacturers' Association spent $70,000 in 1918, and will spend as much or more this year to put wood wheels back in the place they held before wire wheels were so widely advertised. If those manufacturers of wood wheels had begun earlier, their appropriation would have had more value. Now they have to meet opposition. Once they could have simply maintained the good will built up by years of use of wood wheels on horse-drawn vehicles.

Stone Quarry Products

The Barre Quarries and Manufacturers Association spends $75,000 annually on a product that has not one-tenth the appeal that can be made by alkali products. It has advertised for three years and the results are now beginning to show to full advantage. It pays 5 per cent of its gross income into the fund.

Tobacco Growers

The New England Tobacco Growers Association, representing the growers in the Connecticut Valley, has decided to advertise nationally in order to develop a proper appreciation for tobacco, especially wrappers, produced in that section of the country. It is reported that dealers as well as farmers are interested in this project. No amount has yet been determined, but it will be prorated according to the number of acres.

The Cooperage Industry

A fund of $300,000 for a 3-yr. educational campaign in favor of the use of slack barrels is now being raised by the Associated Cooperage Industry of America. Says F. S. Charlot, chairman of the committee:

"We think the slack barrel as a container for food products is better than some of the other containers now in use. We believe if the public could vizualize the unsanitary experiences of a sack of flour or sugar, they would prefer to go to the grocer and have that small quantity dispensed from a clean, sanitary wooden barrel that has protected the contents from contamination. If the public choose to go to their grocer and insist that the flour or sugar be dispensed that way it will eventually be done."

Spreading Gospel of "Safety First"

"Safety First" is a phrase that is familiar to everybody, but few members of the public stop to think who created the slogan and who made it possible. The answer in both cases is the National Safety Council, with headquarters in Chicago, which is spending a large sum each year to spread the gospel of accident prevention. Most of this fund goes for printed matter, because they believe their problem is entirely one of education and continued publicity. The Council was started five years ago and in that brief period it has built up an or-

ganization of 3,758 members, including 150 industries employing over 6,000,000 workmen. The Council has sought to reach these workmen and their employers with fact messages that would get co-operation from all those affected.

Labor Union to Advertise Wood Carving

An old industry, wood carving, is to be advertised by its labor union, the International Wood Carvers Association. The purpose of this publicity is to bring home to the American people the fundamental facts about hand-carved wood and to show that wood carving, into which the best efforts of skilled men have gone, is better than machine-made compo wood. The true motive is to gain the patronage of the wealthy and the artistic for the hand-carved product, that the craft may revert to its former high place among the arts.

The Canners' Campaign

A new educational campaign is now being conducted by the canners of the United States. This is contemplated to last four years and the approximate cost for this period will be about $2,000,000. The form of the campaign will be to heighten the prestige of canned goods as a steady article of diet. The maximum public good will is to be openly and candidly sought in behalf of the entire industry. The canners mean to lay their products and processes on the table and invite public inspection and examination. They want to correct the misinformed and dissipate prejudice.

It is intended that the campaign shall have the following results: A united industry, universality of food of higher standards, larger production, larger consumption, service to the public, and greater confidence of the consumers. Special committees and divisions have been appointed to take care of the different sections of the work. Surrounding them are the various subdivisions which have to do with laboratory work, legal work, finance, inspection, etc.

One part represents the educational and information section and has charge of compiling authentic information concerning all branches of activity in the industry. The second part deals with home economics and spreads the story of canned goods through schools, clubs, stores, conventions, etc., by means of addresses, lectures and demonstrations. It will also have charge of promotion, which will include personal interviews and correspondence with officials, firms, the trade and the members of the industry itself, with addresses at conventions of the industry and of the trade.

Still another section covers the actual educational work that is done by the committee in the way of general publicity, together with investigative work among canners, consumers, dietitians, physicians, pure food reports, food law officials and many other classes. No effort will be spared to show the housewife the healthfulness and safety of canned goods and the care and study given their proper production. It is believed their consumption will be vastly increased.

In Union There Is Strength

These are the illustrations of manufacturers, all of them in competing lines, who are willing to forget fear and jealousy and work together for the common good. They are merging their various individual educational efforts into a common hold to develop and enlarge the market for their product. These men are competitors and will remain so, but they are proceeding on the theory that the more information and the more propaganda they conduct on their particular products, the better it is going to be for everybody in the industry. Manufacturers when disposed to shy at co-operative efforts in the way of marketing and advertising can well afford to learn a lesson from the labor unions. Statisticians tell us that organized labor comprises only about 7 per cent of the country's population. Despite the small proportion, note the way the labor unions win out time and again. They win because they adopt a policy and then go through with it. Whatever may be the criticism of their methods, it must be admitted that they stand together for their common cause.

Business Expansion and Market Saturation

In considering the trade in chemicals, the amount of the trade should not be regarded as a fixed volume of business, but one capable of unlimited expansion, bounded only by the character of the business administration and the study of business conditions, trade opportunities, sales, etc. The limit is reached only when the market has topped the saturation point. Has this point been reached in the use of chlorine for water treatment and disinfection purposes? A paralleling of towns using chlorine products for this purpose with those that do not would bring forth the comparison. As an illustration of a similar condition, though in a dissimilar field, Chairman Hurley of the Shipping Board relates an incident in his own business when he centered a lot of energy on a special sales campaign.

Money was spent in advertising and saleswork, new territory was entered and new customers secured. Results exceeded his expectations. He increased his output, distribution and profits and at the same time reduced his manufacturing and selling costs.

None of his competitors lost any business, however. In fact, by his educational work they gained many new dealers and consumers. He said that it is as if some one suggested that new railroad lines of freight cars to carry goods might take business away from somebody, for we all understand that trade is something to be expanded, something that grows by opening up new territory, by finding new uses, spreading new ideas. It will grow through intensive development, as is done on other products, through advertising, sales, organization and co-operative work generally, whereby business will be created by cultivating the natural desire of every human being for a better standard of living.

Conclusion

Co-operative educational propaganda has tremendous possibilities. It makes a broader and wider market for the entire products and industry through an increase in demand; stabilizes and steadies the market, and makes it less affected by trade depressions and other similar conditions; creates a market for general production before it tries to sell the particular commodity. It lessens the bitterness of competition and advertises the health and strength of the entire industry.

There is opportunity at the present time for co-operative educational work on the greater use of alkali products. To lower the death rate, to make living conditions better and more pleasant, to benefit all mankind —this is the opportunity and the work that is to be done, done in the same way and in the same manner that the various individual industries of this group have been built up, and the results can be considered certain of success.

Industrial Alcohol Under the New Law and Regulations

An Interpretation of the Industrial Aspects of the National Prohibition Act and Regulations 60 and 61—Authorized Uses of Intoxicating Liquors—Procedures—Tax-Free and Completely and Specially Denatured Alcohol—Formulas and Applications

By BURNELL R. TUNISON

BECAUSE of the general misconceptions on the part of the public, and of chemists and manufacturers in particular, concerning the recent national prohibition act and the regulations recently promulgated by the Internal Revenue Bureau for carrying out the provisions of this act, it seems advisable at this time to attempt to explain the essential features of this act and these regulations and indicate in a general way the fundamental changes which will take place due to their operation.

Most people imagine that the national prohibition act has but one aim to accomplish; namely, to prohibit the use of alcohol as an intoxicating beverage. This was the primary consideration, but it may be seen from the title of the act itself that Congress had another aim of almost equal importance. Congress, after mature deliberation and after the passage of most of the features involved in the act itself, decided to call the act as follows:

> An act to prohibit intoxicating beverages, and to regulate the manufacture, production, use and sale of high-proof spirits for other than beverage purposes and to insure an ample supply of alcohol and promote its use in scientific research, and in the development of fuel, dye and other lawful industries.

Dual Purpose of the Act

It will be noted that one of the purposes of the act is to insure an ample supply of alcohol and promote its use in the lawful industries.

In order to carry out the provisions of this act the United States Treasury Department, through the Bureau of Internal Revenue, has issued regulations. These have been issued in two parts: Regulations 60 relating to the manufacture, sale, barter, transportation, importation, exportation, delivery, furnishing, purchase, possession and use of intoxicating liquor; and regulations 61 relating to the production, tax payment, etc., of industrial alcohol and to the manufacture, sale, and use of denatured alcohol.

Most people think that the above-mentioned regulations 60 concern that alcohol which may be used as beverage and that regulations 61 concern all alcohol which is used industrially. It is the writer's opinion that this should be the case, but unfortunately this is not the arrangement made by the powers at Washington. Regulations 60 concern intoxicating liquors, in which the Government has included all pure alcohol used industrially upon which tax is paid. Thus manufacturers of pharmaceuticals or chemical manufacturers who are producing lawful goods which are unfit for beverage purposes and who because of the nature of their product and process cannot use alcohol denatured under formulas prescribed by Government regulations are therefore forced to obtain their alcohol under regulations 60, pay a tax of $4.18 per gal. and be subjected to all the restrictions, red tape, delays, etc., as though they were users of whiskey. Why should these manufacturers be subject to whiskey regulations and taxes any more than a hospital, or college, or a manufacturer of varnish? This red tape is so extensive and the delays which accompany it are so great as to be next to impossible for the busy manufacturer. If any possible substitutes for this alcohol can be discovered, even though they are inferior to alcohol, they will undoubtedly be used.

Authorized Uses of Intoxicating Liquors

Regulations 60 provide that intoxicating liquors may be manufactured, sold, bartered, transported, imported, exported, delivered, furnished, purchased and possessed, and used for *non-beverage* purposes as indicated below, under the conditions and requirements of the regulations.

1. Manufacture of medicinal preparations in accordance with formulas prescribed by the U. S. Pharmacopeia, National Formulary, or the American Institute of Homeopathy, which are unfit for beverage purposes and in the manufacture of other patented, patent, proprietary and other medicines which are unfit for beverage purposes and certain medicinal preparations which are fit for beverage purposes.

   Such preparations must contain no more alcohol than is necessary for the purpose of extraction, solution, or preservation and must contain in each fluid ounce a dose as a whole or in compatible combination of one or more agents of recognized therapeutic value and contain no agents either chemically or physiologically incompatible with the active medicinal agents upon which the medicinal claims are based.

2. By retail druggists or pharmacists in the compounding of medicinal preparations unfit for use for beverage purposes on physicians' prescriptions, and for dispensing as such for medicinal purposes upon physicians' prescriptions.

3. By physicians in the practice of their profession.

4. By persons conducting hospitals and sanatoriums for medicinal, scientific, and manufacturing purposes.

5. (Potable distilled spirits only.) In manufacturing and industrial establishments for first-aid treatment.

6. (Rum only.) In the manufacture of denatured rum as provided by regulations 30.

7. In the manufacture of denatured alcohol as provided by regulations 61.

8. In the manufacture of toilet and antiseptic preparations and solutions that are unfit for use for beverage purposes.

9. In the manufacturing of flavoring extracts and sirups that are unfit for use as beverages or for intoxicating-beverage purposes.

10. For medication by druggists or pharmacists.

11. For laboratory purposes and in general manufacturing and technical processes.

12. By dentists and veterinarians in the course of their practice.

13. (Tax-free alcohol.) By the United States or any governmental agency thereof, or by the several states and territories or any municipal subdivision thereof, or by the District of Columbia, or for the use of any scientific university or college of learning, any laboratory for use exclusively in scientific research, or for use in any hospital or sanatorium.

14. For conversion into beverages containing less than one-half of one per centum of alcohol by volume, as provided by the regulations.
15. For sacramental purposes or like religious rites, as provided in the regulations.
16. In the manufacture of beverages containing less than one-half of one per centum of alcohol by volume under the procedure outlined in the regulations. Provided, however, that intoxicating liquors produced for this purpose may not be exported.
17. In the manufacture of other alcoholic medicinal preparations which are unfit for beverage purposes according to the standards prescribed in the regulations.
18. By retail druggists or pharmacists in the compounding of medicinal preparations unfit for use as beverages on physicians' certificates and for dispensing as such for medicinal purposes upon physicians' prescriptions.
19. By persons conducting hospitals and sanatoriums, for medicinal purposes.
20. By physicians for administering to patients in the practice of their profession.
21. In the production of vinegar as provided in the regulations.

Procedure Necessary in Order to Use Tax-Paid Alcohol

In brief the procedure necessary for a manufacturer to obtain pure alcohol for industrial purposes is as follows:

1. Application must be made to the Federal prohibition director in the state in which the manufacturer desires to use the alcohol (form 1,404 in triplicate). This application after being approved by the director is forwarded to the Federal prohibition commissioner, who may approve the application and issue the permit (form 1,405) to use non-beverage alcohol. Every permit clearly and specifically designates and limits the acts that are permitted and the time when, and the place where such acts may be permitted. It is necessary to make application for each individual purchase, be it for one 10-gal. can or a carload, and have these permits renewed in accordance with the regulations.

2. A bond must accompany the above application (form 1,408 or form 1,409 in duplicate) to insure compliance with the provisions of the act and the regulations. The basis of the penal sum of the bond is $4.20 per proof gallon of distilled spirits. The penal sum of the bond is fixed at approximately twice the sum of the United States internal revenue tax on the alcohol involved. The rate of tax on distilled spirits for non-beverage purposes is fixed by section 600a of the revenue act of 1918, approved Feb. 24, 1919, at $2.20 on each proof gallon [which is equivalent to $4.18 on each wine gallon (231 cu.in.) of 95 per cent alcohol] or wine gallon when below proof, and a proportionate tax at a like rate on all fractional parts of such proof or wine gallon. In no case the penal sum of any bond can be less than $1,000 nor more than $100,000. The bond must be recommended by the Federal prohibition director and referred to the Federal prohibition commissioner. The bond must then be approved by the Federal prohibition commissioner before the manufacturer can obtain a permit to purchase alcohol.

3. After the above permit and bond have been approved it is necessary to make application to the Federal prohibition director for a permit to purchase non-beverage alcohol. Application for permit to purchase must be made on form 1,410 (in triplicate—where transportation is involved four or more copies must be provided). The application must be sworn to before a notary or other person authorized to administer oath, and when approved by the Federal prohibition director becomes a permit. The applicant must describe in particular alcohol to be received by him and must in all cases give the quantity in wine gallons, also in proof gallons, of each kind of liquor on hand at the date of application, and previously received by him during the current calendar year and also since the first day of the quarterly period. Each application must show the name and address of the vendor from whom he proposes to buy, the number of the permit to use alcohol held by the applicant and the address of the premises where the alcohol is to be used. The applicant must be certain that his bond covers the quantity of alcohol outstanding as a debit against the bond, at all times. The permit when approved is forwarded to the vendor who is to furnish the alcohol. It is then possible for the vendor to ship the alcohol to the manufacturer. The vendor must keep careful records, fill out and return a copy of the permit to the director and make reports of all such sales within a specified time. The vendor must send a copy of form 1,410 to the vendee, who must retain it as a permanent record of all such transactions. These permits to purchase for the purpose of manufacturing or selling expire in ninety days after date of approval. Other permits to purchase expire in thirty days.

It is necessary to obtain such a permit for every shipment and the amount required or authorized on each permit must be shipped at one time.

After going through the above procedure the manufacturer may use the alcohol obtained. It is obvious that all this procedure will do very well to cover the purchase of a bottle of whiskey, but it is a real hardship for the persons who purchase alcohol in quantities for lawful manufacturing purposes. In order to carry out these regulations the new office of Federal prohibition director has been created. The Collectors of Internal Revenue, who have had the handling of the tax-paid alcohol regulations, have been relieved of this duty. This new office is not familiar with the handling of this business, it has no uniform methods of procedure, and it is not too much to expect that the user of tax-paid alcohol will suffer long delays in addition to those necessarily experienced due to the Post Office Department in forwarding permits, bonds, etc., from place to place.

Tax-Free Alcohol

Pure ethyl alcohol may be withdrawn free of tax for export under regulations, provided this alcohol is to be used for non-beverage purposes. A permit to export such alcohol may be obtained by making application to the Federal prohibition director (form 1,404 in triplicate) who may approve the application and forward it to the Federal prohibition commissioner, who may approve and issue the permit (form 1,405). Alcohol may then be exported, under further regulations.

Pure undenatured alcohol may be obtained tax free for use under Section 11 of Title III of the national prohibition act, which provides as follows:

> Alcohol may be withdrawn under regulations from any industrial plant or bonded warehouse tax free, by the United States or any governmental agency thereof, or by the several states and territories, or any municipal subdivision thereof, or by the District of Columbia, or for the use of any scientific university or college of learning, any laboratory for use exclusively in scientific research or for use in any hospital or sanatorium.

But any person permitted to obtain alcohol tax free, except the United States and the several states and territories and subdivisions thereof, and the District of

Columbia, must first apply for and secure a permit to purchase the same and give the bonds prescribed for in the case of tax-paid alcohol previously described, but alcohol for use by the United States and the states, territories and subdivisions thereof, and the District of Columbia may be purchased and withdrawn subject only to such regulations as may be prescribed.

Under the provisions of law above referred to the privilege of withdrawing alcohol in bond, free of tax, is held to apply to all scientific or educational institutions incorporated or organized under any Federal, state, or territorial law, or any colleges of learning which have a recognized curriculum and confer degrees after specified periods of attendance at classes or research work, upon proper showing of the facts, any laboratory for use exclusively in scientific research, or to any permanently established hospital or sanatorium in good standing, whether operated for profit or not.

Alcohol withdrawn as above provided may be used in the case of hospitals or sanatoriums only for medicinal, mechanical, and scientific purposes and in the treatment of patients. Scientific or educational institutions or colleges of learning must use such alcohol only for mechanical and scientific purposes, and any laboratory withdrawing alcohol free of tax must use same exclusively in scientific research. The use of the alcohol and resulting products is confined strictly to the premises of the institution withdrawing the alcohol, and in no case is the alcohol to be used in the preparation of food products for use in the institution or elsewhere, nor can products for sale be made from the alcohol withdrawn as above provided.

From the above it may be seen that colleges, universities, hospitals and sanatoriums may obtain tax-free alcohol.

Any laboratory may obtain tax-free alcohol for use exclusively in scientific research.

Procedure to Use Tax-Free Alcohol

Where it is desired to withdraw alcohol, tax free, as above indicated, it is necessary to proceed as follows:

1. An application (form 1,447 in quadruplicate) must be made to the Commissioner of Internal Revenue for a permit to use such alcohol. This application when approved by the Commissioner constitutes the permit.

2. At the time of filing the above application the applicant should give bond (form 1,448 in duplicate) in a sum sufficient to cover double the tax at the non-beverage rate on all alcohol at any time on hand, in transit, or unaccounted for, but at no time may the bond be for less than $1,000.

3. Make application to the proper Collector of Internal Revenue for a withdrawal permit (form 1,449). The United States or any governmental agency thereof must make application direct to the Commissioner of Internal Revenue (form 1,444). Applications by any state or territory or by the District of Columbia must be made to the proper Internal Revenue Collector (form 1,445). This latter procedure also applies to any municipal subdivision of any state or territory, which in addition is required to file the regulation bond for twice the sum of the non-beverage tax. A permit (form 1,450) will be issued which permits obtaining alcohol free of tax for the year, and for the amount covered by the penal sum of the bond.

It is necessary for institutions securing such tax-free alcohol to make a monthly statement (form 1,451) of the amount of alcohol received, on hand, used, etc.

Denatured Alcohol

Alcohol when suitably denatured was first allowed tax free under the act of June 7, 1906, which provides in part:

> That from and after Jan. 1, 1907, domestic alcohol of such degree of proof as may be prescribed by the Commissioner of Internal Revenue, and approved by the Secretary of the Treasury, may be withdrawn from bond without the payment of internal-revenue tax, for use in the arts and industries and for fuel, light and power provided said alcohol shall have been mixed in the presence and under the direction of an authorized Government officer, after withdrawal from the distillery warehouse, with methyl alcohol or other denaturing material or materials, or admixture of the same, suitable to the use for which the alcohol is withdrawn, but which destroys its character as a beverage and renders it unfit for liquid medicinal purposes: such denaturing to be done upon the application of any registered distillery in denaturing bonded warehouses specially designated or set apart for denaturing purposes only, and under conditions prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury.

The amendatory act of March 2, 1907, permitted the use of denatured alcohol in the manufacture of ether and chloroform and other definite chemical substances where the alcohol is changed into other chemical substance and does not appear in the finished product as alcohol.

Prior to the enactment of the national prohibition act the internal revenue tax on distilled spirits (ethyl alcohol, whiskey, brandy, rum, gin, etc.) was $6.40 per proof gallon—50 per cent alcohol by volume—when used for beverage purposes, and $2.20 per such proof gallon when used for non-beverage purposes. Ethyl alcohol was then tax free only when withdrawn from bonded warehouse exclusively for export, or by the United States Government or scientific universities and colleges of learning, or for use in the arts and industries and for fuel, light and power when denatured "with methyl alcohol or other denaturing material or materials, or admixture of the same suitable to the use for which the alcohol is withdrawn but which destroys its character as a beverage and renders it unfit for liquid medicinal purposes." (The quotation is from the original denatured alcohol act of June 7, 1906.)

The national prohibition act under Title III not only extended the use of tax-free ethyl alcohol to "the several states and territories or any municipal subdivision thereof or by the District of Columbia, or any laboratory for use exclusively in scientific research, or for use in any hospital or sanatorium," but said act furthermore provided that alcohol shall also be tax free when denatured "by the admixture of such denaturing materials as shall render the alcohol or any compound in which it is authorized to be used unfit for use as an intoxicating beverage," thus eliminating the restriction against the use of such tax-free denatured alcohol for "liquid medicinal purposes," contained in the aforesaid act of June 7, 1906, and reconciling the definition of denatured alcohol with that established for intoxicating liquor in Title II of the national prohibition act. This act under Title III provides that "alcohol lawfully denatured may, under regulations, be sold free of tax either for domestic use or export."

"Intoxicating liquor" is defined in the national prohibition act to mean practically all substances "containing one-half of one per centum or more of alcohol by volume which are fit for use for beverage purposes," and as the Government is itself fixing standards under such definition, it follows that a manufacturer requiring al-

cohol for non-beverage purposes, i.e., in the production of commodities which are not fit for use for beverage purposes, is lawfully entitled to tax-free alcohol denatured in accordance with formulas suitable for his needs. Expressed differently, lawful products must be made "unfit for use as an intoxicating beverage," and *ipso facto*, they come within the class of industries in which tax-free denatured alcohol may be used under Title III of said act. This construction is sound in principle both from the legal and economic standpoints and, when effectuated by regulations of the Internal Revenue Bureau, will not only remove the present unfair and discriminatory tax upon an essential raw material when used in the manufacture of pharmaceuticals and other articles which are equally important to national welfare as those which now enjoy tax-free alcohol, but will have a salutary effect upon the "H. C. of L." by reducing the price of medicines and other necessaries of life and otherwise placing United States chemical industries upon a plane of efficiency which will enable them to compete successfully with foreign goods in the markets of the world.

Completely Denatured Alcohol

In order to carry out the provisions of the act the Internal Revenue Bureau has authorized the following completely denatured alcohol formulas:

1. This formula, which consisted of 100 parts of ethyl alcohol and 10 parts of methyl alcohol and ½ part benzine, has been suspended.
2. To every 100 parts by volume of ethyl alcohol there shall be added 2 parts by volume of approved wood alcohol and one-half of 1 part by volume of approved pyridine bases.
3. To every 100 parts by volume of ethyl alcohol add 5 parts by volume sulphuric ether, 2 parts by volume benzine, and 1 part by volume pyridine.
4. To every 100 parts by volume of ethyl alcohol there shall be added: 2.5 parts by volume of approved benzol, 0.5 part by volume of nitrobenzol, 0.2 part by volume of approved pine oil (steam distilled).
5. To every 100 parts by volume of ethyl alcohol there shall be added: 2 parts by volume of approved wood alcohol, ¼ part by volume of approved pyridine bases, ½ part by volume of approved benzine (kerosene).

The denaturing materials used are subject to regulation and their specifications may be found in regulations 61, p. 97 et seq.

Alcohol when denatured as above may be used without restriction or regulation except as to marking of containers and is not subject to tax.

Specially Denatured Alcohol

A manufacturer desiring to use specially denatured alcohol for manufacturing purposes must file an application for a permit (form 1,479 in duplicate). The application must contain a description of the location and construction of the storeroom or storerooms in which the manufacturer proposes to store the alcohol, also an explanation in detail as to how the alcohol is to be used. A bond must be filed to insure compliance with regulations, the bonds being not less than $500 nor more than $100,000, in accordance with the schedule shown in Table II.

The formulas of specially denatured alcohol which have been authorized up to the present are as shown in Table I.

TABLE I. AUTHORIZED FORMULAS OF SPECIALLY DENATURED ALCOHOL

(The ethyl alcohol used in these formulas is of 190 deg. proof, or 95 per cent).

(1) 100 gal. ethyl alcohol.
5 gal. methyl (wood) alcohol.

(2) 100 gal. ethyl alcohol.
7 lb. camphor.
5 lb. methyl alcohol (refined).

(2a) 100 gal. ethyl alcohol.
2 gal. methyl alcohol.
2 gal. benzol.

(2b) 100 gal. ethyl alcohol.
½ gal. benzol.

(3) 100 gal. ethyl alcohol.
5 gal. following mixture: 5 gal. methyl alcohol (refined), 1 gal. castor oil, ½ gal. of 36 deg. Bé. caustic soda lye.

(3a) 100 gal. ethyl alcohol.
5 gal. methyl alcohol (refined).

(3b) 100 gal. ethyl alcohol.
1 gal. liquid pine tar.

(4) 100 gal. ethyl alcohol.
1 gal. following solution: 5 gal. aqueous solution containing 40 per cent nicotine; 0.4 lb. acid yellow dye (fast yellow Y); 0.4 lb. tetrazo brilliant blue, 12 B, conc.; water to make 100 gal.

(4) 100 gal. ethyl alcohol.
1 gal. following solution: 5 gal. aqueous solution containing 40 per cent nicotine; 3.6 oz., more or less, of methylene blue; water to make 100 gal.
(This is an alternative for formula 4 above.)

(5) 100 gal. ethyl alcohol.
65 lb. sulphuric ether.
3 lb. cadmium iodide.
3 lb. ammonium iodide.

(6) 100 gal. ethyl alcohol.
3 gal. methyl alcohol (refined).
½ gal. pyridine bases.

(6a) 100 gal. ethyl alcohol.
15 gal. condensed fumes, recovered in the process of manufacture. (Fulminate of mercury.)

(6b) 100 gal. ethyl alcohol.
½ gal. pyridine bases.

(7) Revoked (formula 1 substituted).

(8) 100 gal. ethyl alcohol.
1 gal. pyridine bases.
1 gal. benzol.

(9) 100 gal. ethyl alcohol.
10 gal. acetone.
2 gal. petroleum naphtha.

(10) 100 gal. ethyl alcohol.
2 gal. methyl alcohol.
2 gal. benzol.

(11) 100 gal. ethyl alcohol.
100 lb. sulphuric ether.
10 lb. cadmium iodide.

(12) 100 gal. ethyl alcohol.
1 gal. pyridine bases.
2 gal. benzol.

(12a) 100 gal. ethyl alcohol.
5 gal. benzol.

(13) 100 gal. ethyl alcohol.
5 gal. sulphuric acid.
5 gal. sulphuric ether.

(13a) 100 gal. ethyl alcohol.
10 gal. sulphuric ether.

(14) 100 gal. ethyl alcohol.
5 gal. methyl alcohol (refined).
10 lb. anhydrous zinc chloride.

(15) 100 gal. ethyl alcohol.
3 gal. sulphuric acid.
1 gal. kerosene.

(16) 100 gal. ethyl alcohol.
5 gal. methyl alcohol (refined).
2 gal. benzol.

(17) 100 gal. ethyl alcohol.
5/100 gal. (6¼ fluid oz.) animal oil (Dipple's oil).

(18) 100 gal. ethyl alcohol.
100 gal. vinegar (not less than 9 per cent acetic acid).

(19) 100 gal. ethyl alcohol.
100 gal. ethyl ether.

(20) 100 gal. ethyl alcohol.
5 gal. crude chloroform.

(21) 100 gal. ethyl alcohol.
100 gal. solution containing not less than 4½ per cent acetic acid.

(22) 100 gal. ethyl alcohol.
10 gal. solution of formaldehyde.

(23) 100 gal. ethyl alcohol.
10 gal. acetone.
2 gal. benzol.

(24) 100 gal. ethyl alcohol.
29 gal. sulphuric acid.

(25) 100 gal. ethyl alcohol.
25 lb. iodine.

(26) 100 gal. ethyl alcohol.
5 gal. aniline oil.

(27) 100 gal. ethyl alcohol.
1 gal. oil rosemary.
30 lb. camphor.

(27a) 100 gal. ethyl alcohol.
35 lb. camphor.
1 gal. oil cloves.

(28) 100 gal. ethyl alcohol.
10 gal. benzol.

(29) 100 gal. ethyl alcohol.
5 gal. alcoholic solution acetaldehyde.

(30) 100 gal. ethyl alcohol.
10 gal. methyl alcohol (refined).

(31) 100 gal. ethyl alcohol.
100 lb. soap.
100 lb. glycerine.

(31a) 100 gal. ethyl alcohol.
100 lb. glycerine.
20 lb. hard soap.

(31b) 100 gal. ethyl alcohol.
5½ gal. oil peppermint.
1¼ gal. eucalyptol.
4 lb. menthol crystals.

(32) 100 gal. ethyl alcohol.
5 gal. sulphuric ether.

(33) 100 gal. ethyl alcohol.
30 lb. methyl violet.

TABLE II. RATIO OF THE PENAL SUM OF THE BOND

Less than 100 wine gallons	$500
100 to 200 wine gallons	1,000
201 to 425 wine gallons	2,000
426 to 650 wine gallons	3,000
651 to 900 wine gallons	4,000
901 to 1,100 wine gallons	5,000
1,101 to 2,200 wine gallons	10,000
2,201 to 3,250 wine gallons	15,000
3,251 to 4,400 wine gallons	20,000
4,401 to 5,250 wine gallons	25,000
5,251 to 6,600 wine gallons	30,000
6,601 to 7,750 wine galons	35,000
7,751 to 8,900 wine gallons	40,000
8,901 to 10,000 wine gallons	45,000
10,001 to 11,000 wine gallons	50,000
11,001 to 12,000 wine gallons	55,000
12,001 to 13,000 wine gallons	60,000
13,001 to 14,250 wine gallons	65,000
14,251 to 15,400 wine gallons	70,000
15,401 to 16,500 wine gallons	75,000
16,501 to 17,800 wine gallons	80,000
17,801 to 18,800 wine gallons	85,000
18,801 to 20,000 wine gallons	90,000
20,001 to 21,000 wine gallons	95,000
More than 21,000 wine gallons	100,000

To the user of large quantities of specially denatured alcohol the new schedule represents quite an advantage over the old regulations in that if the manufacturer files a bond for $100,000 he can use any quantity of alcohol he may desire.

Another decided improvement in the present regulations over the old is in the fact that it is now not necessary to renew the withdrawal permits. Manufacturers found under the old regulations that the delays necessary in sending the withdrawal permits from place to place and the delays in renewing withdrawal permits constituted a serious handicap in the continuity of their plant operation. Under regulations 61 once the permit is given it stands until revoked or surrendered.

The formulas of specially denatured alcohol given in Table I have been authorized for use in various products and industries as indicated in Table III.

TABLE III. PRODUCTS AND INDUSTRIES AUTHORIZED TO USE SPECIALLY DENATURED ALCOHOL

FORMULA 1

Acetaldehyde.
Acetphenetidine.
Acetic ether.
Aconite.
Adeps lanæ.
Alkaloids and alkaloidal salts.
Aletrin.
Aloin.
Antipyrin.
Apocynin.
Arbutin.
Asclepiadin.
Avenin.
Artificial flowers.
Ammunition.
Atophan.
Aspirin.
Acetanilid.
Artificial feathers.
Baptisin.
Barometer and thermometer tubes.
Benzoic acid.
Benzaldehyde.
Beta naphthol.
Beta naphthol benzoate.
Brushes.
Benzidine.
Beta-naphthol salicylate.
Benzyl cyanide.
Benzon.
Chelonin.
Cimicifugin.
Collodion.
Collodion corn remedy.
Concentrations (nonliquid).
Confectioner's colors.
Coumarin.
Cutlery.
Cocoa butter.
Composition billiard and pocket balls.
Chloroform.
Compasses.
Creosote carbonate.
Colors and bronze powders.
Chloral hydrate.
Camphor, synthetic.
Cements.
Dental alloy.
Dandelion and digitalis. (Resin of, solid and powdered extracts of.)
Disinfectant germicide.
Door checks.
Dyestuffs.
Dimethylglyoxime.
Dinitro toluene.
Digestive ferments.
Diethylaniline.
Ethyl acetate.
Ethyl propionate.
Ethyl butyrate.
Essential oil orris.
Ethyl chloride.
Embalming fluid.
Eosine.
Ethyl bromide.
Ether.
Ethyl aniline.
Enamel.
Extracting glycerine from distillery slop.
Filaments for incandescent lamps.
Formaldazone.
Fertilizers.
Fulminate of mercury.
Formaldehyde.
Gaduol.
Gelatine capsules.
Gentian (solid extract).
Glycerophosphates.
Guaiacol.
Guaiacol carbonate.
Gum and pyroxylin solutions.
Gallocyanine.
Gas mantles.
Hats.
Heliotropin.
Hydrastis (alkaloid of).
Hexachlorbenzol.
Inks.
Inulin and iriscin.
Imitation leather.
Isinglass.
Imitation ivory goods.
Jalapin (nonliquid concentration of).
Jewelry and watches.
Japans.
Lacquers, pastes, and varnishes from soluble cotton.
Leather substitutes.
Leather-goods finish.
Lacquers.
Liquor cresolis compound.
Mandrake (powdered and solid extract of).
Mirrors.
Moldings and picture frames.
Monobromated camphor.
Moth repellant.
Mica insulators.
Mucilage, paste, and glue.
Motor fuel.
Nonscatterable glass.
Nitroso betanaphthol.
Orthotoluolsulphamide.
Oils, greases, lubricants, and soluble thread-cutting oils.
Oleoresins.
Paints.
Phenolphthalein.
Phytolacin (concentration of).
Photographic dry plates and films.
Print paper and enlargements.
Postal-card colors.
Polish preparations for metals and furniture.
Pepsin and similar products.
Potassium hydroxide.
Podophyllin resin and similar products.
Powdered drugs and extracts.
Photographic engravings.
Phenyl cinchoninic acid.
Pyroxylin cements.
Refining mineral oils.
Refining precious metals.
Resin of scammony.
Resorcin.
Salol.
Santonine and strychnine.
Solid extracts.
Soaps (transparent and liquid).
Shellac varnish.
Shoe polish.
Silverware and bronze.
Smokeless powder.
Surgical ligatures.
Soldering flux.
Sodium benzoate.
Sulphonic acid and paraffine.
Salicylic aldehyde.
Solution and solvent of nitrocellulose.
Solidified alcohol.
Salophen.
Saponin.
Salicylic acid.
Saccharine.
Shellac thinner.
Stains.
Sterilizing solution for corks.
Silk fabrics.
Synthetic mustard oil.
Shampoo, liquid.
Shampoo, jelly.
Stencil paper.
Tannic acid.
Tinfoil and bottle caps.
Terpin hydrate.
Textile cleansing soap.
Toluidine.
Transparent paper.
Transparent soap for waterproofing cement.
Trinitrotoluol.
Theobromine.
Thermostatic devices.
Varnish remover.
Viburnum (concentration).
Water colors.
Wood finish.
Wool fat.
Washing lenses.
Wood filler.
Watches.

OTHER FORMULAS

(2) Pyraline and similar products.
(2a) Celluloid; pyraline and similar products.
(2b) Acetic ether; acetyphenetidine (conditional); dyes, diethyl barbituric acid (barbital); ethyl sulphate (for use in manufacture of acetphenetidine); phenacetine; pyroxline plastics; ketone; Michelers; sulphuric ether (in connection with the production of powder); synthetic camphor; trinitrotoluol; viscaloid; white petroleum oils; ethyl sulphate.
(3) Transparent soap; shampoo; shampoo jelly.
(3a) Cutting oils; shampoo; shampoo jelly; transparent soap.
(3b) Liquid soap; shampoo; shampoo jelly.
(4) Cigars; cigarettes; smoking, chewing tobacco; deodorants.
(5) Photo enlargements; photoprints; photo-engravings; photographic collodion.
(6) Fulminate of mercury.
(6a) Fulminate of mercury.
(6b) Acetphenetidine; chloral hydrate; dichlorethane; ethyl acetate; ethyl butyrate; ethyl chloride; parafulminate of mercury; paraphenetidine; acetic ether; ethyl bromide.
(7) Revoked.
(8) Ethyl chloride; fine chemicals; sulphonmethane; dyes.
(9) Monobromated camphor; purification of rubber; santonine; strychnine; tannic acid.
(10) Ethyl acetate (conditional), lacquers, pastes and varnishes from soluble cotton.
(11) Photographic collodion; photo-engraving; photoprints.
(12) Imitation leather (see also formula 12a); soluble cotton.
(12a) Acetphenetidine; barbital; hydrazoanisol; imitation leather; milk protein; paranitrophenatol; refining potassium and sodium hydrate; saponification of the waxes of acid-fast bacteria; smokeless powder; terpin hydrate; trinitrotoluol; benzoic acid ethyl ester; dye intermediates; imitation rubber.
(13) Sulphuric ether. (See also formula 13a).
(13a) Celery oil; certified food colors; dry extracts for food products; ethereal oil; protargentum; sodium ethyl sulphate; sulphuric ether.
(14) Ethyl chloride. (See also formula 1 and 8.)
(15) Ethyl bromide; ethyl chloride; nitrous ether; pure acetic ether.
(16) B-naphthol; byproducts from distillery slop; glycerophosphates; lacquers for food containers; phenal cinchonic acid; acetanilid; acid salicylic; acetphenetidine; ammonium; benzonaphthol; betanaphthol benzoate; codeine; diacetylmorphine; ethyl morphine; homatropin; morphine; salicylate cocaine; sodium, strontium; salol. (See also formula 1.)
(17) Acetphenetidine; chloral hydrate; dichlorethane; ethyl acetate; ethyl chloride; ethylene gas; paraphenetidine.
(18) Acetate of lime; acetone; vinegar.
(19) Artificial silk; backing of films; byproducts from distillery slop. (See also formula 16.) Collodion; ethyl acetate; iodizers; solvent for nitrocellulose; photofilms; photo engravings.
(20) Chloroform (conditional).
(21) Acetate of lime (conditional).
(22) For preserving formaldehyde, U. S. P.
(23) Liniment for external use only.
(24) Phenacetin; ethyl acetate (conditional); ethyl butyrate; ethyl propionate; ethyl valerate.
(25) Tincture of iodine, U. S. P.; tr. iodi Fortier, N. F.; tr. iodine Churchill's; tr. iodine 3½ per cent.
(26) Ethylaniline and diethylaniline.
(27) Soap liniment, U. S. P.; chloroform liniment, U. S. P.; liquid and green soap, in accordance with U. S. P. except as to content of camphor and oil of rosemary.
(28) Motor fuel (conditional).
(29) Aldehydes (conditional); glacial acetic acid (conditional).
(30) Chemical and physical laboratory purposes, only in accordance with the provisions of T. D. 2793 (no recovery for re-use); photo dry plates; manufacturing vegetable oils; varnish; white petroleum oils (conditional).
(31) Tooth paste.
(31a) Tooth paste.
(31b) Tooth paste.
(32) Ethylene (conditional).
(33) Meat branding inks (conditional).

The term methanol is now used to indicate methyl alcohol.

The types and quality of the denaturing materials used in the preparation of the formulas given are controlled by the United States Internal Revenue Bureau and details as to their specifications may be found in regulations 61, pp. 97-104.

The following table giving the specific gravities and the weight of 1 gal. of the specially denatured alcohols has been found of considerable value to manufacturers:

SPECIFIC GRAVITY AND WEIGHT OF 1 GALLON OF SPECIALLY DENATURED ALCOHOL

(Weight of 1 gallon water at 15.6 deg. C., 8.32823 lb.)

The Commissioner of Internal Revenue will consider any formula for special denaturation that may be submitted by any manufacturer in any art or industry and will determine (1) whether or not the manufacture in which it is proposed to use the alcohol belongs to a class in which tax-free alcohol withdrawn under the provisions of the law can be used; (2) whether or not it is practicable to permit the use of the proposed denaturant and at the same time properly safeguard the revenue. But one special denaturant will be authorized for the same class of industries, unless it shall be shown that there is good reason for additional special denaturants.

The Commissioner will announce from time to time the formulas of denaturants that will be permitted in the several classes of industries in which tax-free alcohol can be used.

Conclusions

Users of alcohol should keep in mind that five different formulas (four now that formula 1 is suspended) for completely denatured alcohol have been authorized, which alcohol may be sold, distributed and used without any restriction, regulation or taxes. Formulas for many specially denatured alcohols have been authorized, which formulas are of such a nature as to be suitable for most industries; these alcohols being free of tax but distributed and used under regulation. To those who must use pure ethyl alcohol there are two possibilities. 1. If they desire the alcohol for scientific research only (and a few other cases as mentioned) it may be obtained free of tax, but is subject to Government regulation. The other case is that of manufacturers who may obtain alcohol for non-beverage purposes under Government regulation and pay a tax of $4.18 per gallon of 95 per cent alcohol.

385 Edgecombe Avenue,
New York, N. Y.

Blast Roasting at Port Pirie*

By Gilbert Rigg
Metallurgist, Associated Smelters Proprietary, Ltd.

THE introduction of granulated slag into the roaster charge when dealing with Broken Hill leady concentrates has been found to have certain advantages apart from the economy in the use of ironstone, which the slag largely replaces. This practice has been developed at the Port Pirie smelters during the past eight months.

The concentrates used at Port Pirie are divided into two classes, according to their mode of origin; concentrates from the jigs and tables, and slime concentrates from the flotation plants. The following analyses illustrate the composition of the two classes:

	Concentrate Per cent	Slime Per cent		Concentrate Per cent	Slime Per cent
Pb	63.0	57.0	CaO	1.5	1.5
Zn	7.0	11.0	Al_2O_3	1.5	1.0
S	14.5	18.0	SiO_2	5.0	3.5
FeO, MnO	6.0	5.5			

A certain amount of oxidized ore is used, and is usually referred to as siliceous ore. The following is an analysis:

	Per cent		Per cent
Pb	20.0	CaO	2.0
Zn	4.5	Al_2O_3	8.0
FeO, MnO	15.0	SiO_2	40.0

In order to make clear the nature of the present innovation, some account of the roasting practice in general is essential. Roasting is done in two stages, a preliminary or "A" roast on a D. & L. machine, followed by a crushing of the A-sinter, and a final or "B" roast of the A-sinter on Dwight & Lloyd machines or Huntington-Heberlein pots. In both cases the charge is the same and was, until the introduction of granulated blast-furnace slag, substantially as follows:

	Per cent		Per cent
Concentrates	49.0	Limestone	6.0
Slime concentrates	18.5	Ironstone	14.5
Siliceous ore	12.0		

Blast-Roasting Charge

This charge varied a little in accordance with small variations in the composition of the concentrates.

Originally, the fluxes were crushed through a ½-in. screen. Experience has shown that this was much too coarse. The notion that coarse pieces in a charge undergoing blast roasting do open up the charge to the passage of the blast is to some extent true. But, on the other hand, such opening up is local, and encourages the blast to pass through the charge at favored spots, while the denser parts of the charge go short. Other factors also militate against this practice. The concentrates, especially the slime concentrates, are finely divided, and, regarded as a uniformly distributed material, would no doubt effectively block the passage of the blast. Such materials, however, have the advantages of their defects. Finely-divided substances, when mixed damp, have a strong tendency to cohere into large and porous aggregates, and in consequence present a relatively coarse structure. The presence of coarse pieces of ironstone and limestone interferes with this process by mechanically breaking down the aggregates during mixing.

Again, seeing that the blast-roasting charge only sinters and never enters the molten condition, pieces of limestone iron ¼ in. to ½ in. diameter are attacked only at the surface. They are, however, largely burned to lime, which slakes when the sinter is

*From the *Industrial Australian and Mining Standard*, vol. 62, p. 597 (1919).

exposed to the air, and causes it to crumble and become unsuitable for the blast furnace.

Moreover, the sinter coming from the D. & L. machines on which the final or "B" roast is performed is found to contain the coarser pieces of ironstone in an unaltered condition. The coarse unassimilated material helps to weaken the sinter. The recognition of these facts led the author to use the fluxes in much finer form than before.

In the neighborhood of the limestone quarries on Wardang Island, Spencer's Gulf, are sand dunes composed of disintegrated limestone of the same composition as the solid limestone of which the island is composed. This sand will pass a 40-mesh screen. Substituted for the crushed limestone, it was found to work perfectly. The elimination of sulphur was good, and the final sinter was free from lime as such, and more resistant to exposure.

Ironstone screened through $\frac{1}{8}$ in. gave good results in substantially smaller amount than had been used previously, and owing to the denser character of the charge, it gave a stronger sinter, and, while roasting, gave less trouble through blow-holes and dust losses than previously.

A similar line of action in regard to the crushing of the "A" sinter before passing to the "B" machine or H-H pots was attended with similar results.

The D. & L. sinter derived from this charge averages about as follows:

	Per cent		Per cent
Pb	44 to 45	MnO	3 to 4
Zn	5 to 6	CaO	4 to 5
SiO_2	9 to 10	S	2 to 3
FeO	16 to 18		

On the blast furnaces this sinter gave satisfactory results, the only addition made on the furnace being a little limestone.

Composition of the Slag

The composition of the slag corresponding to this sinter is as follows:

	Per cent		Per cent
SiO_2	21.0	ZnO	13.5
FeO	33.5	Pb	2.0
MnO	4.5		Oz.
CaO	14.0	Ag	0.75

The composition of this slag is unusual, and defies any attempt to figure out a silicate formula from it. It runs very fluid and separates well. Microscopical examination of thin slices shows that it is composed of two major constituents. The ground-mass is colorless, in thin section, and resembles fayalite, and is probably a lime-ferrous orthosilicate. Scattered through this is a black to dark brown constituent, with indications of octahedral crystallization; also green octahedral crystals referred to gahnite are present. Frequently the silicate crystals are full of parallel rods, arranged like the teeth of a comb, and suggesting a constituent which separated from the silicate at the moment of freezing of the latter. The slag is decidedly magnetic, the powder being appreciably attracted by a permanent magnet.

Unfortunately time has not yet been available for the final working out and diagnosis of these sections. Arrangements have now been made for a thorough investigation of the problem. In the meantime the following working hypothesis has been adopted:

The silicate ground-mass is an orthosilicate of CaO, MgO, FeO and ZnO. The black to brown mineral is a ferrite ($ROFe_2O_3$), mainly a ferrite of Zn, possibly also a ferrite of lime and manganese, or, in other words, a franklinite. These two constituents exist in the molten slag in a state of mutual solution. In addition, it appears that ZnO is also present dissolved in the slag. The orientation of the rods referred to corresponds to the crystallographic structures of the silicate base, and, as suggested, they appear to have separated out at the freezing point of the latter.

Structure of the Slag

The structure of this slag is of considerable interest, both scientific and technical, and it is expected that its final elucidation will not now be long delayed. Meanwhile, there is some evidence is favor of the foregoing hypothesis. In the first place ferric oxide is present in the slag. Its quantitative estimation is rendered very difficult owing to the presence of 3 per cent of sulphur in the latter, which reduces the Fe to the ferrous state when the slag is treated with acid, but its presence has been qualitatively established. The formation of magnetite under blast-furnace conditions when Fe is present and SiO_2 is deficient is well known. The color and high opacity of the dark constituent and the magnetic character of the slag lend color to the view that a molecule of the construction $ROFe_2O_3$ is present.

Again, experiments on the use of a reverberatory matte settler yielded large masses of magnetic material which formed on the hearth and side walls and choked up the furnace unless the temperature was maintained high enough to prevent the separation. Incidentally, no matte separated at this temperature either.

Influence of Adding Slag to Charge

Accepting this hypothesis provisionally, the next question that arose was, what would be the behavior of the ferrite if added to the roaster charge as a substitute for ironstone; in other words, if instead of using new ironstone blast-furnace slag was returned to the furnace. There were several cogent reasons for doing this if possible. In the first place, there is good ground for believing that in the roasting charge ferric oxide serves as a carrier of oxygen to adjacent sulphides. This can only take place if the Fe is absorbed into the sinter. It has already been shown that ironstone in pieces too coarse for this absorption come through the process unchanged, and can be discarded from the charge without injury. The Fe in the slag is already in finely-divided form, and the slag is very easily taken up by the sinter. Further, it was thought that the addition of slag would tend to strengthen the sinter which erred on the side of fragility.

The Zn content of the sinter would naturally be increased by addition of zinc-bearing slag to the charge, and in consequence the blast-furnace slag likewise, and the interesting question arose whether a Zn content could be tolerated in the slag which would make it commercially feasible to treat the latter for recovery of Zn. As regards this amount of Zn upsetting the running of the blast furnaces, this was felt to depend mainly on how completely the sulphur was eliminated from the sinter. With sulphur well below 3 per cent, troubles due to Zn largely disappear. These latter are mainly due to zinky matte and to accretion, in which ZnS plays an important part.

Finally, the economy which would accrue from a reduction in the amount of ironstone required, and the cost of crushing it, were attractive.

Trials with crushed slag had been made some time previously with unsatisfactory results. Granulated slag being available, it was decided to utilize the slag in this form. It seemed to be in an ideal condition for this purpose. It consists of a mass of porous disintegrated grains, the great majority passing readily through a 4-mesh screen and yet free from powder, such as is produced in crushing. Such a material would give the maximum of useful surface and porosity.

Large-Scale Operation

After some preliminary small-scale experiments, which were highly encouraging, the substitution of granulated slag for ironstone was put to work on the entire plant, turning out about 400 tons of lead per day. The following charge was used:

	Per cent	Per cent		Per cent	Per cent
Concentrates	40.0	49.0	Limestone sand	8.3	6.0
Slime concentrates	25.5	18.5	Ironstone	4.5	14.5
Siliceous ore	10.0	12.0	Slag	10.0	

For the sake of comparison, the composition of the original charge without slag is given in the second column. It will be noted that the percentage of slime concentrates has been increased in the new charge, this class of concentrate being more difficult to desulphurize than the coarse concentrate under ordinary conditions.

Average figures for the D. & L. sinter from this charge were:

	Per cent		Per cent
Pb	44 to 45	MnO	3 to 4
Zn	7 to 8	CaO	5 to 6
SiO_2	11 to 12	S	2 to 3
FeO	11 to 13		

This sinter was of good grade and worked well on the blast furnaces. The ZnO content of the blast-furnace slag was 17 per cent and gave no trouble.

Increasing the Lead Content

After running some weeks on this charge, it was decided to try increasing the proportion of concentrates in order to improve the Pb content of the sinter. A supply of siliceous ore not being available at this time, the deficiency in silica was made up by increasing the amount of slag, and adding a silica sand carrying 85 per cent SiO_2. The charge had the following composition:

	Per cent		Per cent
Concentrates	47.0	Ironstone	4.0
Slime concentrates	27.5	Slag	12.5
Limestone sand	7.0	Sand (SiO_2)	2.0

The charge sintered well, the sinter having the following composition:

	D. & L. Per cent	H. & H. Per cent		D. & L. Per cent	H. & H. Per cent
Pb	47.5	48.5	MnO	3.0	3.0
Zn	7.5	7.5	CaO	6.0	5.5
SiO_2	8.0	8.5	S	2.8	2.7
FeO	13.0	14.0			

Both D. & L. and H. & H. sinter were made from the same charge mixture, the small differences shown being due to slight variations in the constituents. The increased Pb tenor is noticeable. Up to 50 per cent of Pb has been carried without trouble, although before the introduction of the granulated slag 44 to 45 per cent Pb was the limit at which satisfactory sintering practice could be maintained. The equality in S content of both classes of sinter is also of interest, as prior to the introduction of slag the H. & H. sinter usually ran distinctly higher in S than the D. & L.

This sinter ran well in the blast furnaces, the slag having the following composition:

	Per cent		Per cent
SiO_2	20.7	CaO	12.0
FeO	29.8	ZnO	18.7
MnO	4.8		

The FeO content is 29.8 per cent, as against 33.5 per cent when slag is not used. No Zn troubles were met with.

The next charge run had the following composition:

	Per cent		Per cent
Concentrates	47.0	Ironstone	2.0
Slime concentrates	27.5	Slag	15.0
Limestone sand	7.0	Sand (SiO_2)	1.5

This also sintered well. The composition of the blast-furnace slag was:

	Per cent		Per cent
SiO_2	24.2	CaO	11.0
FeO	25.6	ZnO	20.0
MnO	5.3		

This slag ran well, and no Zn troubles were present.

In the foregoing slag analysis the Fe is expressed as FeO, as it also is in the sinters, but part of the Fe is present as Fe_2O_3 in both cases.

No additions of limestone or any other fluxes have been made to the blast furnaces since the slag-sinter was used, the charge consisting of sinter, slag-shells and coke only. The Pb and Ag contents of the slag average 1 per cent and 0.5 oz., respectively.

The use of granulated slag as a constituent of the roaster charge has now been proved. Its advantages may be summed up as follows:

(1) Better sinter physically, both D. & L. and H. & H.

(2) Economy in the use of ironstone.

(3) Economy in crushing ironstone.

(4) Higher Pb content of sinter, and consequent reduction in cost per unit of Pb roasted.

(5) Higher ZnO content of slag, which brings its recovery within the limits of commercial practice.

The new slag, while apparently of the same type as the old, differs markedly from it in its higher SiO_2, lower FeO and higher ZnO content. Its further investigation, both from a theoretical and practical standpoint, promises interesting results.

Melbourne, Australia.

Industrial Uses of the Prickly Pear

The prickly pear, more particularly *Opuntia inermis*, or pest pear, is a kind of cactus which already covers about 22,000,000 acres in Australia and is spreading at the rate of a million acres per year. As a reserve food for cattle it has some value, but it is not a well-balanced ration and needs mixing. In Ceylon, India and South Africa it is used as a fertilizer, the broken parts being buried in wide trenches 18 in. deep. This involves considerable labor. The fruits have been used for the manufacture of alcohol in Spain and Sicily, but the enterprise was not commercially successful. For 1 gal. of alcohol 140 lb. of fruit is needed, and to make the enterprise successful ten tons of fruit to the acre would be required and a method of mechanical harvesting not yet invented. As paper-making material the yield of pulp is slight, while the fibers are short and lack felting qualities.

Arsenic pentoxide and arsenic chloride are used for exterminating the plants, and it is found that the cochineal insect has almost exterminated the true pear in India and Ceylon. This plant (*Opuntia monacentha*) is, however, not a serious pest, and the insects will attack no other. Research is in process to discover the action of insects and fungi upon the offending plant.

Synopsis of Recent Chemical and Metallurgical Literature

Improved Methods of Ore Dressing Graphite Ores.—The *Canadian Mining Journal* for Jan. 16, 1920, contains an article by CHARLES SPEARMAN giving a general outline of ore-dressing methods for graphite ores. In the separation and concentration of graphite from its gangue, the ideal condition is attained when the flake, as a whole, is completely separated from the accompanying gangue and recovered, without material modification to its physical condition, as a concentrated product. The separation is a step in the operation not easily accomplished commercially, but the recovery of the naked flake by concentration is relatively a simple matter; in fact, the treatment of graphite ore is more of a problem in ore dressing than it is one of concentration.

It is advantageous to effect the complete separation of the flake from the gangue previous to concentration. The widespread practice of refining or finishing concentrates necessitates an auxiliary ore-dressing unit.

Prior to the commercial application of flotation to graphite ore, the usual ore-dressing plant was crude and inefficient and it is doubtful if any of them were operated at a profit. The ore was first dried "bone dry" in kilns and crushed in rolls, the drying operation being necessary to prevent "pancaking" of the ore on the face of the rolls. After crushing, the product was delivered to a set of "heavy-duty" rolls for further comminution and then delivered to a series of finer rolls, usually of the flour mill type. The product of the fine rolls was screened between sets with the object of removing the flake graphite as oversize. Some mills of this type were equipped with as many as ten sets of rolls and screens, with the result that most of the flake was completely disintegrated before reaching the final screen.

The screens removed the oversize, which consisted of naked flake, flake with adhering gangue, mica and free gangue. The oversize was refined or finished in auxiliary units, which consisted of fine rolls and French buhr stones which disintegrated the brittle gangue and incidentally the graphite flakes. The product of this operation was screened to remove the undersize, the oversize being commercial flake. Quite often dry tables were included in the circuit in order to relieve the burden on the screens and rolls and to recover additional flake. The dust-laden atmosphere attending these operations is a very serious objection.

The commercial product resulting from this method of concentration is thin, flattened and polished flakes, in which the physical structure of the original flakes is rendered discontinuous due to the action of the rolls. And the ordinary handling of this product results in an abnormal quantity of the lower grade flake.

Recent practice in the separation of the flake from the accompanying gangue is less complicated than the method described and is more efficient in that it produces a higher grade product at a lower cost.

The drying of the ore is eliminated and after preliminary crushing the ore is fed to a ball mill and ground wet. The load and feed of the mill is so adjusted as to insure a free discharge and to exclude the liberated flake from the zone of disintegration as soon as possible. This action is sometimes accelerated by the addition of oil to the feed to the ball mill, which then acts on the principle of the Macquestin tube section. The pulp from the ball mill is fed to a mixer and then to an Alderson hydraulic classifier, from which most of the gangue-bound flake is returned as oversize to the mill for retreatment, while the free flake for the most part follows the undersize to a Spearman flotation concentrator.

After concentration the flake is dried and graded, and the portion containing adhering gangue is retreated the same as the classifier oversize. The low-grade product is about 3 to 10 per cent of the concentrate. The remainder of the flake after the removal of the dust is No. 1 crucible stock.

The flake resulting from the improved method of concentration may be described as coherent, thick, "bold" and "rugged," that is, having rough edges and surfaces. It is much higher in carbon and has a higher specific gravity than flake from the roll treatment. This is due to the fact that powdered gangue is impressed into the relatively non-coherent mass of minute flakes which constitute the product of roll treatment.

The special advantages of the wet method of separation applied to graphite ore are lower cost of installation and operation, greater quantity of a high-grade product, better grade, and smaller quantity of low-grade product, the elimination of the dust nuisance and simplicity of operation.

Manufacture of Carbon Electrodes.—The increasing demand for electrodes during the latter part of the war period resulted in the erection of a new plant at Niagara Falls, which has now been finished as the Republic Carbon Co. A description of this thoroughly modern plant will be found in the Jan. 15, 1920, issue of *Iron Age*.[1]

The raw materials used are: Anthracite, coke, petroleum coke, retort carbon, hard and soft pitch, tar and oil. After preliminary crushing, the coal or cokes are calcined in specially designed electric furnaces, and transferred by belt conveyors to the grinding building, which is equipped with a Raymond mill and Sturtevant and other types of crushers. By means of blowing and elevating conveyors, the finely ground raw materials are delivered at the top of the mixer building. After screening, the materials pass to a series of storage tanks, from which they may be fed as required to weighing cars which dump into the mixing machines. Here the binders are added and the mass is thoroughly kneaded and then molded into lumps resembling a large cheese. The plastic mass is extended through dies of various shapes in a 3,000-ton hydraulic press.

The last stage in the manufacture is the baking and annealing of the electrodes. In the baking building, there are 28 producer gas-fired baking furnaces operating on the ring principle. The green electrodes are placed in saggers, using coke, coal or sand as packing material. These are then placed in the various compartments of the furnaces and buried in some insulating and protective material. Pyrometric control lating and protective material.

Pyrometric control regulates both the baking and the annealing.

[1] "New Plant for Making Carbon Electrodes," *Iron Age*, vol. 105, p. 188, Jan. 15, 1920.

Recent Chemical and Metallurgical Patents

Australian Patents

Complete specifications of Australian patents may be obtained from the Government Printer, Melbourne, one shilling each.

Desulphurizing Ore.—To dispense with hand or mechanical rabbling during desulphurizing of, say, zinc sulphide, the ore is caused to descend in a finely-divided state through an upcurrent of pre-heated air in a narrow zigzag passage formed by inclined shelves within a vertical furnace. The air required for roasting is pre-heated by the hot combustion gases leaving the furnace and is forced through pipes into the lower part of the zigzag passages. The roasted ore falls into chambers, from which it is removed by screw conveyors. A series of pokeholes is arranged in the front wall of the furnace to maintain a free passage for the falling ore. (Australian Pat. 9,269, G. RIGG, Victoria. Nov. 25, 1919.)

Manufacturing Oil Pastes.—To obviate drying the material when preparing oil pastes, such as white lead, from lead precipitates, the precipitate is subjected to the action of sodium biborate or other boracic acid salts in the proportion of not more than eighteen grains or less than seven grains to one pound of wet precipitate. The required quantity of oil is then added, and the mass subjected to mechanical working and mixing, the water being expelled and the oil combining with the precipitate. (Australian Pat. 9,458, H. P. FLETCHER, N. S. W. Dec. 2, 1919.)

Glue and Gelatine.—To produce glue and gelatine from the pith of horns and the bones of cattle, these materials are subjected to a solution consisting of one part hydrochloric acid and eight parts of water for a period of five days. This step is repeated till the material has been treated with five solutions. After being washed for two periods of 24 hr. in two separate baths of cold water, the material undergoes two applications, each of 24 hr. duration, of a solution of 100 lb. lime to 100 gal. of water. Two further washings of cold water are given and the material is then dried and boiled for 12 to 18 hr. The thin liquid, which is skimmed off and dried, comprises pure gelatine, while the thick liquid contains the glue. Sulphuric acid may be used in addition to, or instead of, hydrochloric acid. (Australian Pat. 10,447, J. TURNER, Victoria. Nov. 25, 1919.)

Treatment of Battery Separators.—To render wood suitable for separating positive and negative elements in storage cells, the strips are boiled for an hour in a solution of 4 oz. of washing soda to a gallon of water and after cooling are placed in a dilute solution of sulphuric acid of 1.150 sp. gr. for one hour and finally washed. (Australian Pat. 10,120, L. ROWSON, New Zealand. Nov. 18, 1919.)

Recovery of Metallic Zinc.—To keep within predetermined limits the accumulation of impurities in a cyclic process for the electrodeposition of zinc from solutions obtained by the leaching of wasted ores with sulphuric acid (spent electrolyte), a certain proportion of the zinc-bearing solution is withdrawn from each cycle and an equivalent amount of water is added. The deflected solution is treated with zinc dust in the presence of a soluble arsenic compound for the precipitation of the cobalt, and the manganese is eliminated by electrolytic oxidation and by treatment with suitable oxidizing agents. The purified zinc sulphate solution is then mixed with barium sulphide for the manufacture of lithopone in the ordinary way. (Australian Pat. 9,442. H. W. GEPP, Victoria, assigned to Electrolytic Zinc Co. of Australia Proprietary, Ltd. Dec. 16, 1919.)

Ore Roasting.—To sulphatize zinc sulphide ore preparatory to leaching with sulphuric acid, the ore is subjected to multi-stage roasting. In the first stage the ore is roasted at a high temperature with a controlled supply of air for partial elimination of the sulphur and to insure a sufficient concentration of the sulphur dioxide for the production of sulphuric acid. In the second the ore is roasted at a lower temperature, preferably 725 deg. C., with excess of air. The iron oxide content of the ore functions as a catalyst converting the sulphur dioxide into the trioxide which is absorbed by the zinc oxide to form sulphate. Alternatively, a more or less complete elimination of the sulphur may be effected in the first stage, and in the second stage, unroasted sulphide may be added to the first calcine. (Australian Pat. 9,224. ELECTROLYTIC ZINC CO. OF AUSTRALASIA PROPRIETARY, LTD., assignee of H. W. Gepp, Victoria. Nov. 18, 1919.)

American Patents

Complete specifications of any of the United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Benzaldehyde From Toluene by Catalytic Oxidation.—Toluene vapor mixed with air, oxygen or ozone and a certain amount of diluent gases or steam is passed over molybdenum oxide, MoO_3 contained in a tube heated to 500 deg. C. Benzaldehyde is formed according to the reaction:

$$C_6H_5CH_3 + O_2 = C_6H_5CHO + H_2O$$

(1,321,959; JOHN M. WEISS and CHARLES R. DOWNS, assignors to The Barrett Co.; Nov. 18, 1919.)

Sulphonation With Sulphur Trioxide.—By sulphonating aromatic hydrocarbons in the vapor phase with SO_3 from the contact chambers, the formation of water as a byproduct and the presence of excess sulphuric acid in the sulphonic acid are avoided. The rapidity and degree of sulphonation depend upon many factors, such as temperature, time of contact, concentration of SO_3 in gaseous mixture, the particular hydrocarbon used, and the pressure. The sulphonic acid formed may be treated directly with sodium hydroxide for the purpose of replacing the HSO_3 group by hydroxyl. (1,321,994; CHARLES R. DOWNS, assignor to The Barrett Co.; Nov. 18, 1919.)

Chlorinated Pyroxylin.—The inflammability of pyroxylin may be reduced in the following manner, according to ALEXANDER SCHWARCMAN, of Buffalo, N. Y. Commercial pyroxylin is dissolved in CH_3OH containing 5 per cent acetone. This solution is diluted with CCl_4 and treated with chlorine in the presence of a carrier such as $ZnCl_2$ or $SnCl_2$ until from 5 to 8 per cent by weight of chlorine has been absorbed by the pyroxylin. The solvents are removed by evaporation and the chlorinated pyroxylin washed, neutralized and dried in the usual manner. (1,323,792; assigned to Spencer, Kellogg & Sons, Inc.; Dec. 2, 1919.)

Personal

JAY A. CARPENTER, metallurgical engineer, has removed his office from Tonopah, Nev., to 1006 South Hill Street, Los Angeles, Cal., where he has a laboratory for ore testing.

FRANK L. DRIVER, president of the Driver-Harris Co,. Harrison, N. J., left on March 6 for a two months' trip through England and France.

A. E. DRUCKER has been appointed professor of metallurgy at the Wisconsin State School of Mines.

L. W. EMERSON has joined the engineering staff of the Chile Exploration Co., and will be at its New York City office, 120 Broadway.

H. F. FISH, formerly in the research department of the Great Western Sugar Co., Denver, Col., has been appointed special research assistant in the joint investigation of the fatigue of metals, by the board of trustees of the University of Illinois. Mr. Fish will be located at Champaign, Ill.

ADOLPH HARVITT, who has been on the research staff of the Davison Chemical Co., Baltimore, Md., sailed for Japan on business connected with the foreign shipments of the company.

J. D. JONES, who since last September has been general superintendent of the Algoma Steel Works, Sault Ste. Marie, Canada, has now been appointed general manager in succession to Captain David Kyle, deceased.

HAROLD E. KETCHUM, for the past three years vice-president in charge of construction for the American Nitrogen Products Co., Seattle, Wash., has been made general manager of the Francis A. Vaughn Manufacturing Co., Milwaukee, Wis., manufacturer of tools and construction equipment. During his connection with the American Nitrogen Products Co. Mr. Ketchum built and equipped the factory at La Grande, Wash., for the production of sodium nitrite, using surface power from Tacoma. He also built a factory for the production of concentrated nitric acid and sodium nitrate at Vancouver, B. C., using surface power in the British Columbia Electric Co. Both of these factories are equipped with the Wielgolaski long-arc furnace.

H. A. LINCH of the engineering staff of the Dorr Co. is on his way to South America. He expects to be gone several months and will visit Peru, Chile and Bolivia. His South American address will be Hotel Londres, Antofogasta, Chile.

ERIC A. LOF of the power and mining engineering department of the General Electric Co., Schenectady, N. Y., sailed for Norway March 11.

W. MOTHERWELL, recently from Broken Hill, Australia, is conducting flotation tests at the 85 Mine, Valedon, N. M.

Judge JOHN BARTON PAYNE of Chicago, chairman of the United States Shipping Board, was selected by President Wilson to succeed Franklin K. Lane as Secretary of the Interior. He assumed his duties March 1.

A. R. STEVENSON has severed his connections with Schaar & Co. and is now with the Deegan Supply Co., Chicago, Ill.

MAXIMILIAN TOCH of New York City has been appointed adjunct professor of industrial chemistry in Cooper Union, New York, and will co-operate in the development of a new 4-yr. day course in industrial chemistry to be started in September.

HARRY VIVIAN has been appointed chief engineer of the Calumet & Hecla and subsidiary companies, succeeding the late Edward S. Grierson.

S. S. VOORHEES, chemist, Bureau of Standards, was operated on for acute appendicitis March 1. His continued improvement is confidently expected.

GEORGE WEINTRAUB, formerly chief chemist of the Rare Metals Co., Perth Amboy, N. J., is now metallurgical chemist of the Standard Chemical Co., Canonsburg, Pa.

FRANK R. WICKS has opened an office and testing laboratory at 1006 South Hill Street, Los Angeles, Cal.

Obituary

Captain DAVID KYLE, vice-president and director of the Algoma Steel Corporation, died of pneumonia following influenza.

EDWARD S. GRIERSON, chief engineer for the Calumet & Hecla Mining Co., died recently at his home in Calumet, Mich., following a long illness from pernicious anæmia.

Dr. FRANCIS C. PHILLIPS, who was in charge of the chemistry department, University of Pittsburgh, where he was professor of chemistry for forty years, died at his home in Pittsburgh, Pa., on Feb. 16, of influenza and pneumonia.

Current Market Reports

The Non-Ferrous Metal Market

New York, March 15.—A number of minor changes will be noted in the metal market. In an attempt to enliven the apathetic copper market, producers have offered spot for 18⅝c.

		Cents per Lb.
Copper, electrolytic		19.00
Aluminum, 98 to 99 per cent.		31@32
Antimony, wholesale lots		11.25
Nickel, ordinary		43.00
Nickel, electrolytic		45.00
Tin, Straits, spot		63.00
Lead, New York, spot		9.50
Lead, E. St. Louis, spot		9.25
Zinc, spot, New York		9.05
Zinc, spot, E. St. Louis		8.75

The Iron and Steel Market

Pittsburgh, Pa., March 12, 1920.

There is additional information that production has been increasing and is greatly exceeding both the predictions made by producers and the expectations entertained by consumers two or three months ago. The monthly report of the American Iron and Steel Institute, in which there was a hiatus for the months of September to December inclusive, states that in February 2,865,124 gross tons of ingots were produced by thirty companies which in 1918 contributed 84.03 per cent to the country's total. Counting the number of working days in the month and year and allowing for production by the capacity not reporting, this indicates that in February ingots were produced at the rate of 44,200,000 tons per annum, against a rate of 40,-

650,000 tons for January and an average during the last three months of the old year of somewhat less than 30,000,000 tons. Eventually the steel mills may show an ability to produce more steel than would be expected of them, judged by their output in 1916 plus allowances for new construction since, but on that basis indicated capacity is now in the neighborhood of 50,000,000 tons of ingots per annum. On this basis, the rate of production rose from about 45 per cent on Oct. 1 to about 75 per cent on Dec. 31, averaging about 58 per cent for the three months. By the Institute reports the average was 81 per cent in January and 88 per cent in February, suggesting a March rate of about 95 per cent, having regard to the facts that March is almost invariably a favorable month for production and that the transportation difficulties that interfered with production in February are disappearing. Thus there would be 88 per cent for this quarter, against 58 per cent for last quarter, an improvement of 52 per cent, with still better prospects for the second quarter of the year.

Indicated Output of Steel Larger Than Anticipated

These are much larger outputs than consumers of steel have been expecting. At some times it might be of little consequence to the market observer that consumers of steel misjudged the situation and prospects, but, considering what consumers have been doing in the past three months, bidding up prices on themselves and becoming more anxious to buy as producers were reserved about selling when they wished to catch up with their overdue deliveries, it is a very important thing, marketwise, if consumers were acting upon incorrect premises, yet there can scarcely be a doubt that such has been the case.

The runaway in steel prices has probably gone altogether as far as it is to go, and it now appears that it has affected early deliveries chiefly. The United States Steel Corporation is still on the basis of March 21 or Industrial Board prices. Several large and conservative independents will not, according to the present outlook, quote above 3c. for bars, 3.10c. for shapes and 3.25c. for plates to their regular customers for third quarter deliveries, these prices being $13, $13 and $12 respectively above the Steel Corporation prices, while they are the prices to which these independents gradually mounted in the past few weeks as they closed with their customers for second quarter. The opening for third quarter will probably occur within about thirty days. The Steel Corporation is already largely sold beyond that quarter. The smaller independents, who do simply a prompt business, securing delivery premiums when they can, are not yet thinking of third quarter at all, but as the weeks pass will probably secure smaller and smaller premiums. In sheets the top point for small lots for early delivery seems to have been passed about a fortnight ago, with a 10c. basis for common black as the limit, comparing with 4.35c. in the Industrial Board price schedule.

The bi-monthly settlement of the sliding wage scale of the mills controlled by the Amalgamated Association showed 4.65c. for 26, 27 and 28 gage sheets and $7.40 for tin plate, as average invoice prices of shipments from the selected mills during January and February. The showing in tin plate is not representative of the industry as a whole, it chancing that the selected mills have been doing a premium business when many others have not, except in selling export tin plate at above the regular $7 market price. The Steel Corporation is, of course, not represented at all in these settlements.

Pig Iron

The pig-iron market appears to have passed the crest in its great upward movement. Apart from the recent decline of $1.50 in basic iron, the market for extended deliveries is not lower in the Central West, though there have been slight declines at Buffalo and Philadelphia. The market, however, has been dull and almost stagnant, and the common opinion is that the next general price movement will be downward. An important fact is that the premium on prompt foundry iron, once amounting to several dollars a ton, has disappeared entirely. There is no precedent for pig iron being at a high price and at the same time showing no premium for prompt delivery. The valley market remains at $42 for bessemer, $41.50 for basic, $42 for foundry and $43.25 for malleable, prompt or forward, freight to Pittsburgh being $1.40.

Ferro-Alloys

Prompt ferromanganese is a trifle easier, carloads standing at about $200, while later deliveries, to July 1, bring prices on a scale down to about $170 for June. Second half remains at $160, delivered. English has been quoted at $150, c.i.f., but it is uncertain whether purchases could now be made at the figure. Electrolytic ferrosilicon is $80@$81, delivered, for 50 per cent and $140 for 75 per cent. Bessemer ferrosilicon is quoted at $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, f.o.b. Jackson or New Straitsville, Ohio. Electrolytic ferrosilicon, 12 to 14 per cent, is now competitive with the blast-furnace ferrosilicon in the case of a number of consumers, and is reported to have sold as low as $65, delivered.

Chemical and Allied Industrial Markets

New York, March 12, 1920.

Owing to the present high prices and small spot stocks, trading has not been very heavy. Foreign demand is still strong on some of the leading items and it is reported that Europe is destitute of some of these more active materials. The present scale of prices is due to remain until producers can catch up with their contracts and the pressure of the transportation problem can be relieved.

General Chemicals

Sodium nitrite is the outstanding item on the list this week. Last week's quotation of 15@17c. per lb. jumped to 65@68c. This rise was occasioned by the depletion of spot stocks, which have been steadily decreasing during the past few weeks. At present this item is unobtainable in any quantity here in the East, but relief is expected from the West and from shipments from abroad. *Nickel salt, single,* has tightened up slightly and at present is quoted at 16@17c. per lb., while the *double* holds firm at 14c. *Salt cake* has been exceptionally active during the week and with present low supply of spot material the low price came up from $18 to $21 per ton. *Ammonia* products are still scarce; quotations remain firm at last week's price, *aqua,* 26 deg., being sold at 8¾@10¾c. per lb. *White granular sal ammoniac* is still firm at 15@16c. per lb. with very little material obtainable at this price. *Methyl alcohol,* wood, is unobtainable in the market at present. Some small quantities are being transferred to old customers but at extreme prices. In sympathy with alcohol, *formaldehyde* remains scarce and prohibitive in price, 85c.@$1 per lb. being asked. *Barium chloride* is still firm at $140@$150 per ton, with no material changing hands even at this level. Producers are completely sold out and it seems to be the opinion of a good many that this condition will prevail for some time.

Coal-Tar Products

There has been no change of importance in this market during the past week. Spot stocks on most of the items remain small and previous price levels are holding firm. Producers are for the most part sold up on contract for periods ranging from three to six months. The future of the spot market, because of this condition, does not look especially bright. All *aniline* products are still practically unobtainable, the most important of these being *dimethylaniline,* which is quoted nominally at 90c.@$1.50, with no material to offer at the top price. *Naphthalene, crushed,* holds firm at 6@8c. per lb., while *flake* is quoted at 7@8c. and the *balls* 8½@10c. per lb. It is the opinion of one large producer that there will be an increase in price during the last half as indicated by decreasing surplus stocks on hand at present.

Naval Stores

This market is firmer in prices than it has been for the past few weeks, due entirely to scarcity of supplies. Foreign buyers have not come back in the market with the usual demand owing to a continued unfavorable rate of exchange. *Turpentine* advanced to $2.05 per gal., against $1.93 of

last week. This strengthening is due to scarcity in the Southern market, which has had the effect of tightening New York prices. All grades of the *rosins* are decidedly firmer. B-D grades are listed at $18@$18.75, against a low mark of $17 for last week, while E-I advanced to $18.90@$19.25 and K-H $19.35@$20 per 280 lb. There is no immediate relief in sight until the new crop arrives and in the meantime the large spring paint demand threatens to send prices still higher.

Crude Rubber

Para grades are still on the decline, *upriver* fine going down to 40½@42c., coarse 30½@32c. and *caucho ball* 31@32¾c. per lb. *Plantations* had a rise on the strength of the jump in exchange with some slight activity on the part of buyers.

Vegetable Oils

This market remained firm throughout the week with some slight fluctuation on *cottonseed*, crude, f.o.b. mill, which finished up at 17½@18c. per lb. There is an impending shortage in the *linseed* branch which threatens to be serious unless the crushers can be relieved by Argentine seed. Quotations are slightly firmer in tone, *raw*, carlots, being listed at $1.79, and *boiled*, carlots, $1.82 per gal.

Miscellaneous Materials

A continued active market for the past few months on *feldspar* combined with a series of unfortunate conditions, the latest being the severe weather which interfered with surface mining, has seriously crippled this industry. One large producer is refusing to consider any more contracts for the present even at the Government price of $18 per ton. The nominal quotation of $13.50@$18 per ton, ground grade, f.o.b. Tennessee and New York State remains firm, although there has been no business, on a large scale, reported at these prices.

The *shellac* market is somewhat easier owing to the increase in sterling. Orange fine is still quoted nominally at $1.45 per lb. while superfine is listed at $1.50@$1.60 per lb.

No. 1 crucible flake *graphite* dropped 50 per cent following the armistice and has never recovered. The prices quoted in the table may be regarded as delivered prices, approximately the same throughout the country. There are graphite mines in Texas, Alabama, Pennsylvania, etc. In Alabama there are twenty to thirty mines producing No. 1 flake, but only four or five of them are in operation, owing to reduced demand occasioned by the cessation of war. Those companies which have developed or are developing a market for other than crucible graphite stand a better chance for permanency.

Chicago, March 10, 1920.

Apparent apathy on the part of buyers marks trading in all lines, caused probably by the fact that price levels seem too high to justify buying beyond actual current needs. But few price changes of moment are recorded. Continued demand in excess of supply causes pine-tar products to continue their upward trend and a suddenly developed shortage in supply of *sodium nitrite* has provoked a spectacular boost. In general it may be said that, with most materials, production is rather less than normal demand and prices are firm with an upward tendency in most cases.

Chicago's growing importance in the *naval stores* industry is indicated by the recent increase in office space and storage capacity made by the General Naval Stores Co. at this point. Their capacity for business will be trebled by the enlargement.

Heavy Chemicals

Continuous demand by the dye industry coupled with shortage in production and a minimum of imports has forced *sodium nitrite* up to unreasonable levels. From a price of 18c. per lb. in carlots two weeks ago, 50c. is now easily obtained for the small lots available. Some sales were made at an even higher figure and it appears that 50c. will be the minimum for some time to come. *Alkali* products continue their upward trend, as spot stocks are low and export demand is still heavy. *Caustic soda*, solid, is quoted at $5 cwt., f.o.b. works. The same figure is named for goods from Chicago stock, but supplies are so low as to render this figure practically nominal. *Bleaching powder* is held at $3.25 per cwt. at the works, 25c. per cwt. more being asked for small lots for local delivery. Scarcity of *soda ash* has forced the figure up to $2.50@$2.65 per cwt. for spots, with but little less asked on contract. *Sal soda* is also up to $1.40 per cwt. in carloads.

Conditions remain the same as for the past six weeks in *alcohol, ethyl*, 190 proof, being quoted at $5.50@$5.70 in barrels, *methyl*, 97 per cent, at $2.40@$2.60 per gal. and *denatured*, 180 proof, at 78@83c. Spot stocks are almost out of existence and these quotations in most instances are purely nominal. The same is true as concerns *formaldehyde*, what little trading occurred ranging from 60@80c. with the most recent offer being made at 70c. New interest is being shown in *blue vitriol* (copper sulphate), producers showing no anxiety to close at the current figure of $9 per cwt. in carlots. *Chlorine* in cylinders holds at 9c. per lb. in spite of light demand, heavy withdrawals on contracts leading to the expectation of a better selling market. *Sodium bichromate* is easier, current transactions in small lots going at 39c. per lb. f.o.b. Chicago. A shortage has recently developed in *white sal ammoniac*, present market being 20c. per lb. for spots.

Acids, as for some time past, show but little activity, prices holding firm without change. The only exception is in *boric*, which steady demand has forced up to $16 per cwt. in cars for immediate delivery.

Coal-Tar Products

Supply conditions are steadily improving and as a result most prices should soon recede. This does not mean the market is weak. Rather, better supply and lower prices will make trading more active, buyers having stayed out of the market as much as possible during the recently prevailing poor buying conditions. Quotations of 30c. per gal. is still asked for *benzol* for spot shipment, 27c. for contract. *Toluol* is quoted at 28c. in carload quantities. Stocks of *anilines* are still seriously depleted, the *oil* being quoted at 35c. per lb. and *salts* at 50c. for immediate delivery. *Dimethylaniline, diphenylamine and paranitraniline*, being completely off the market, are not quotable. *Salicylic acid* has advanced, with present quotations 50c. per lb. for technical grade and 60c. for U. S. P. *Benzoic* remains unchanged at 75c. for technical and 90c. for U. S. P.

Vegetable Oils

Practical cessation of export trade has caused accumulation of excess stocks in all lines and induced a falling market. Plentiful supply with demand poor, is the case on every item. *Cocoanut oil* is off 2c., *manila*, in sellers' tanks, f.o.b. coast, being quoted at 17c.; refined, in barrels, at 20c. f.o.b. Chicago. *Prime corn oil*, in tanks, is bringing 15c. f.o.b. Chicago, with no inquiries being made for inferior grades. *Cottonseed oil* is very weak, carload quotation on crude being 15½@16c. and on *prime summer yellow*, 18@19c. delivered. Refined, in barrels, is going slowly on the local market at 23c.

A peculiar twist has developed in the *linseed oil* market. At the same time the wholesale market shows a cut from $1.75 per gal. to $1.65 per gal. for carlots, jobbers have raised their price on less than 5-bbl. lots 2c. per gal., $2.05 being the present price. It does not seem that this high price on small quantities can be maintained very long. *Soya bean oil* shares in the general decline, quotations now being, for tanks, f.o.b. coast, 16c.; for barrels, immediate delivery in Chicago, 17½@18c. and for refined, in barrels, Chicago, 19½@20c.

Flotation Oils—Naval Stores

The impending new crop causes buyers to be cautious and demand correspondingly light, but prices continue to ascend. *Turpentine* is now quoted at $2.30 in cars at Chicago, $2.42 being asked for barrels. This is an advance of 21c. in two weeks. *Pine oil* is also a little higher, $1.60 being asked for the small quantity of .933 pure steam distilled available and $1.55 for the destructively distilled. *Rosin* shows some additional strength, today's Chicago quotation on F grade being $19.75 per cwt., with other grades in proportion. *Pine tar oil* is held at 40c., under excellent demand.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	–	$0.60 – $0.65
Acetone	lb.	$0.13 – $0.15	.16 – .18
Acid, acetic, 28 per cent	cwt.	2.75 – 3.00	3.00 – 3.25
Acetic, 56 per cent	cwt.	6.00 – 6.50	7.00 – 7.50

Alum, ammonia lump	lb.	.04 – .05	.05½ – .06
Alum, potash lump	lb.	.08 – .08½	.09 – .09½
Alum, chrome lump	lb.	.15 – .16	.18 – .20
Aluminum sulphate, commercial	lb.	.01½ – .02	.02½ – .02½
Aluminum sulphate, iron free	lb.	.02½ – .03	.03½ – .03½
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.08¾ – .10¾	.11 – .12
Ammonia, anhydrous, cylinders (100-150 lb.)	lb.	.33 – .35	.35 – .37
Ammonium carbonate, powder	lb.	.16 – .16½	.17 – .17½
Ammonium chloride, granular (white salammoniac)	lb.	.15 – .16	.17 – .19
Ammonium chloride, granular (gray salammoniac)	lb.	.13 – .13½	.14 – .14½
Ammonium nitrate	lb.	.10 – .12	–
Ammonium sulphate	lb.	.05 –	.06 –
Amylacetate	gal.	–	3.65 – 3.75
Arsenic, oxide, lumps (white arsenic)	lb.	–	.10½ – .11
Arsenic, sulphide, powdered (red arsenic)	lb.	.23 – .24	–
Barium chloride	ton	140.00–150.00	160.00 – 170.00
Barium dioxide (peroxide)	lb.	.26 – .27	.28 – .30
Barium nitrate	lb.	.11 – .12	.13 – .14
Barium sulphate (precip.) (blanc fixe)	lb.	.03 – .03½	.05½ – .06
Bleaching powder (see calcium hypochlorite)		–	–
Blue vitriol (see copper sulphate)		–	–
Borax (see sodium borate)		–	–
Brimstone (see sulphur, roll)		–	–
Bromine	lb.	.85 – .95	–
Calcium acetate	cwt.	2.00 – 2.05	2.10 –
Calcium carbide	lb.	–	.04¾ .05
Calcium chloride, fused, lump	ton	20.00 – 25.00	30.00 – 40.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02¼
Calcium hypochlorite (bleaching powder)	cwt.	3.50 – 3.75	4.00 – 4.50
Calcium peroxide	lb.	–	1.50 – 1.70
Calcium phosphate, monobasic	lb.	–	.75 – .80
Calcium sulphate, pure	lb.	–	.25 – .30
Carbon bisulphide	lb.	.06 – .08	.09 – .10
Carbon tetrachloride, drums	lb.	.10½ – .11	.12 – .15½
Carbonyl chloride (phosgene)	lb.	–	.80 – 1.05
Caustic potash (see potassium hydroxide)		–	–
Caustic soda (see sodium hydroxide)		–	–
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.06 – .07	.08 – .09
Chloroform	lb.	.28 – .29	.30 – .31
Cobalt oxide	lb.	–	2.00 – 2.05
Copperas (see iron sulphate)		–	–
Copper carbonate, green precipitate	lb.	.27 – .28	.29 – .31
Copper cyanide	lb.	–	.65 – .70
Copper sulphate, crystals	lb.	.08¼ – .09	.09 – .09½
Cream of tartar (see potassium bitartrate)		–	–
Epsom salt (see magnesium sulphate)		–	–
Formaldehyde, 40 per cent (nominal)	lb.	–	.85 – 1.00
Glauber's salt (see sodium sulphate)		–	–
Glycerine	lb.	–	.24½ – .26
Iodine, resublimed	lb.	–	4.10 – 4.30
Iron oxide, red	lb.	–	.03 – .20
Iron sulphate (copperas)	cwt.	1.20 –	1.25 – 1.75
Lead acetate, normal	lb.	.12 – .13	.14 – .23
Lead arsenate (paste)	lb.	–	.13 – .17
Lead nitrate, crystals	lb.	–	.70 – .80
Litharge	lb.	.14 – .15	.15½ – .16
Lithium carbonate	lb.	–	1.50 –
Magnesium carbonate, technical	lb.	–	.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	3.40 – 3.55	3.60 – 3.75
Magnesium sulphate, commercial	100 lb.	3.00 – 3.10	3.10 – 3.25
Nickel salt, double	lb.	.14 –	.15 –
Nickel salt, single	lb.	.16 – .17	.17½ –
Phosgene (see carbonyl chloride)		–	–
Phosphorus, red	lb.	–	.60 – .65
Phosphorus, yellow	lb.	–	.35 – .37
Potassium bichromate	lb.	.32 – .33	.34 – .37
Potassium bitartrate (cream of Tartar)	lb.	–	.56 – .60
Potassium bromide, granular	lb.	–	.50 – .65
Potassium carbonate, U. S. P.	lb.	.60 –	.65 – .70
Potassium carbonate, crude	lb.	.26 – .27	.28 – .30
Potassium chlorate, crystals	lb.	.16 – .20	.21 –
Potassium hydroxide (caustic potash)	lb.	.25 – .32	.35 – .42
Potassium iodide	lb.	–	3.35 – 3.60
Potassium nitrate	lb.	.19 –	.21 –
Potassium permanganate	lb.	–	$0.65 – $0.95
Potassium prussiate, red	lb.	1.00 – 1.05	1.10 – 1.20
Potassium prussiate, yellow	lb.	.34 – .36	.40 – .70
Potassium sulphate	ton	$225.00 –	–
Rochelle salts (see sodium potas. tartrate)		–	–
Salammoniac (see ammonium chloride)		–	–
Sal soda (see sodium carbonate)		–	–
Salt cake	ton	21.00 – 22.00	–
Silver cyanide (nominal)	oz.	–	1.25 –
Silver nitrate (nominal)	oz.	–	.81⅝ – .82½
Soda ash, light	100 lb.	2.50 – 2.60	– 3.00
Soda ash, dense	100 lb.	2.70 – 2.75	– 3.10
Sodium acetate	lb.	.06½ – .07	.07 – .08
Sodium bicarbonate	100 lb.	2.40 –	2.75 – 3.00
Sodium bichromate	lb.	.33 – .34	.35 – .36
Sodium bisulphate (nitre cake)	ton	7.00 – 7.50	8.00 – 10.00
Sodium bisulphite Powered	lb.	.05½ – .06½	.07 – .07½
Sodium borate (borax)	lb.	.08½ – .08¾	– .09
Sodium carbonate (sal soda)	100 lb.	1.35 – 1.40	1.50 – 1.75
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.24 – .25	.26 – .27
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	5.00 – 6.00	6.10 – 6.25
Sodium hyposulphite	lb.	–	.03¾ – .04
Sodium molybdate	lb.	2.50 –	3.25 –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	–	.65 – .68
Sodium peroxide, powdered	lb.	–	.30 – .32
Sodium phosphate, dibasic	lb.	.03¾ – .04½	.04½ – .05
Sodium potassium tartrate (Rochelle salts)	lb.	.40 – .42	.43 – .45½
Sodium prussiate, yellow	lb.	.23 – .29	.30 – .40
Sodium silicate, solution (40 deg.)	lb.	.01¾ – .02	.02 – .02¼
Sodium silicate, solution (60 deg.)	lb.	.02¼ – .03	.05 – .06
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.15 – 1.50	1.60 – 2.00
Sodium sulphide, crystal, 60–62 per cent (conc)	lb.	–	.05 – .06
Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 –
Sulphur chloride	lb.	.05½ –	.06 –
Sulphur, crude	ton	22.00 –	–
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½	.46 – .50
Tin oxide	lb.	.50 – .60	.65 –
Zinc carbonate, precipitate	lb.	–	.20 –
Zinc chloride, gran	lb.	.13 –	.13½ – .15
Zinc cyanide	lb.	.49 –	.50 –
Zinc dust	lb.	.11¼ – .12½	.13 – .15
Zinc oxide, dry American	lb.	–	.09½ – .12
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

*Nominal quotations.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.40 —	.50
Aniline oil, drums extra	lb.	.34 —	.45
Aniline salts	lb.	.42 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.25 —	1.35
Benzidine, sulphate	lb.	1.00 —	1.15
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech.	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.55
Beta naphthol, sublimed	lb.	.65 —	.80
Beta naphthol, tech.	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 —	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 —	1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.85 —	1.00
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.70
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline (nominal)	lb.	.95 —	1.50
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine (nominal)	lb.	.55 —	.65
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3.75 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.80 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.12 —	.18
Paranitraniline	lb.	1.00 —	1.35
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.15 —	3.00
Paratoluidine	lb.	1.75 —	2.50
Phthalic anhydride	lb.	.60 —	.70
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 —	.25
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.43 —	.45
Salicylic acid, U. S. P.	lb.	.55 —	.60
Salol	lb.	.90 —	1.00

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.22	—	$0 27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.25	—	.30
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	....
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	....
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42	—	$0.45
Beeswax, refined, yellow	lb.	.47	—	.48
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1. (nominal)	lb.	.80	—	.88
Carnauba, No. 2, regular (nominal)	lb.	.65	—	.78
Carnauba, No. 3, North Country (nominal)	lb.	.46	—	.48
Japan	lb.	.17	—	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.....	—	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	—	.10½
Paraffine waxes, refined, 118-120 m.p.	lb.	.....	—	.08
Paraffine waxes, refined, 128-130 m.p.	lb.	.11	—	.11¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.....	—	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	.....	—	.14
Stearic acid, single pressed	lb.	.23	—	.26
Stearic acid, double pressed	lb.	.28	—	.29
Stearic acid, triple pressed	lb.	.32	—	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.48
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.60
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$18.00	—	$18.75
Rosin E-I	280 lb.	18.90	—	19.25
Rosin K-N	280 lb.	19.35	—	20.00
Rosin W. G.-W. W.	280 lb.	21.50	—	24.75
Wood rosin, bbl.	280 lb.	15.50	—	17.50
Spirits of turpentine	gal.	.....	—	2.05
Wood turpentine, steam dist.	gal.	.....	—	1.93
Wood turpentine, dest. dist.	gal.	.....	—	1.85
Pine tar pitch, bbl.	200 lb.	8.50	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	14.75
Retort tar, bbl.	500 lb.	15.00	—	15.25
Rosin oil, first run	gal.	.93	—	.95
Rosin oil, second run	gal.	.96	—	.97
Rosin oil, third run	gal.	1.10	—	1.15
Rosin oil, fourth run	gal.	.....	—	1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33¾
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30¼
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.40½	—	$0.42
Upriver coarse	lb.	.30½	—	.32
Upriver caucho ball	lb.	.31	—	.32¼
Plantation—First latex crepe	lb.	.48½	—	50
Ribbed smoked sheets	lb.	.48	—	.48¾
Brown crepe, thin, clean	lb.	.45	—	....
Amber crepe No. 1	lb.	.46	—	47

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.19	—	$0.20
Castor oil, AA, in bbls.	lb.	.20	—	.23
China wood oil, in bbls.	lb.	.23½	—	.25½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18	—	.19½
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½	—	.23½
Corn oil, crude, in bbls.	lb.	.17	—	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½	—	.18
Cottonseed oil, summer yellow	lb.	.18½	—	.19½
Cottonseed oil, winter yellow	lb.	.22	—	.24
Linseed oil, raw, car lots	gal.	1.79	—	
Linseed oil, raw, tank cars	gal.	1.72	—	
Linseed oil, boiled, car lots	gal.	1.82	—	
Olive oil, commercial	gal.	2.50	—	3.00
Palm, Lagos	lb.	.16	—	.16½
Palm, bright red	lb.	.15½	—	.17½
Palm, Niger	lb.	.15	—	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.22½	—	.24
Peanut oil, refined, in bbls.	lb.	.27	—	.28
Rapeseed oil, refined in bbls.	gal.	1.70	—	
Rapeseed oil, blown, in bbls.	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.18½	—	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.16¾	—	.20

FISH

Winter pressed Menhaden	gal.	$1.15	—	....
Yellow bleached Menhaden	gal.	1.20	—	....
White bleached Menhaden	gal.	1.22	—	....
Blown Menhaden	gal.	1.28	—	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00	—	$40.00
Barytes, off color	ton	20.00	—	25.00
Blanc fixe, dry	lb.	.04½	—	.05½
Blanc fixe, pulp	ton	30.00	—	50.00
Casein	lb.	.35	—	.36
Chalk, English, extra light	lb.	.05	—	.07
Chalk, English, light	lb.	.04½	—	.06
Chalk, English, dense	lb.	.04	—	.05
China clay (Kaolin), imported, lump	ton	25.00	—	35.00
China clay (Kaolin), imported, powdered	ton	30.00	—	60.00
China clay (Kaolin), domestic, lump	ton	10.00	—	20.00
China clay (Kaolin), domestic, powdered	ton	25.00	—	40.00
Feldspar (nominal)	ton	13.50	—	18.00
*Fluor spar, acid grade, lump, f.o.b. mines	net ton	30.00	—	45.00
*Fluor spar, acid grade, ground, f.o.b. mines	net ton	52.00	—	57.00
Fuller's earth, domestic, powdered	ton	25.00	—	30.00
Fuller's earth, imported, powdered	ton	35.00	—	40.00
Graphite, crucible, 85% carbon content	lb.	.....	—	.07½

Talc, imported	ton	60.00	—	70.00

*Nominal

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fire clay	1,000	38-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	33-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	45-50 at Mt. Union, Penn

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20	—	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21	—	.22
Ferro-manganese, 70-80% Mn	gross ton	160.00	—	175.00
Spiegeleisen, 16-20% Mn	gross ton	50.00	—	65.00
Ferro-molybdenum, per lb. of Mo	lb.	2.25	—	2.75
Ferro-silicon, 50%	gross ton	85.00	—	95.00
Ferro-silicon, 75%	gross ton	150.00	—	175.00
Ferro-silicon, 10-15%	gross ton	45.00	—	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb	.90	—	1.10
Ferro-uranium, 35-50%	lb	7.00	—	
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50	—	7.50

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.60	—	$0.85
Chrome ore, 48% and over	unit	1.00	—	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00	—	
*Coke, furnace, f.o.b. ovens	net ton	6.00	—	
Petroleum coke, refinery, Atlantic seaboard	net ton	.....	—	14.00
Fluor spar, gravel, f.o.b. mines	net ton		—	25.00
Manganese ore, 45% Mn and over	unit	.75	—	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00	—	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75	—	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00	—	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.25	—	6.75
Uranium oxide, 96%	lb.	2.75	—	3.00
Vanadium pentoxide, 99%	lb.	6.00	—	
Pyrites, foreign, lump	unit	.17	—	
Pyrites, foreign, fine	unit	17	—

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

HUMBOLDT—The Silver Belt Mining Co. plans to install a 50-ton flotation mill at its silver mine. Ben Rybon, Prescott, gen. mgr.

KOFA—The New King of Arizona Mining Co., Los Angeles, Cal., plans to construct a 20-ton stamp mill with cyanide equipment at its gold mine, here. W. J. Johnson, mgr.

MAYER—The Peck Consolidated Mining Co. plans to construct a 100-ton cyanide plant. A. Anderson, supt.

TUBAC—R. R. Mason, Patagonia, plans to install a 50-ton flotation concentration mill, in connection with the Royal Blue Mine, near here.

TUCSON—The Midland Copper Co. plans to install a 100-ton flotation mill on its North Star property. E. G. Bush, pres.

TUCSON—The Mineral Hill Consolidated Copper Co. plans to install a 300-ton flotation mill at its copper mine. F. G. Farish, genl. mgr.

TUCSON—The Silver Peak Mining Co. plans to install a stamp and concentrating mill at its silver mine. Paul Von Feldt, supt.

California

BIGGS—The city voted $45,000 bonds to improve the sewer system, including the construction of a sewage disposal plant.

EL MONTE—B. B. Moore, city clk., will receive bids until March 18 for the construction of a sewer system and a circular septic tank, Imhoff type, for the city. Estimated cost, over $10,000. Olmsted & Gillelen, Hollingsworth Bldg., Los Angeles, engrs.

TURLOCK—The city trustees are having plans prepared for the construction of a sewage disposal plant. Estimated cost, $10,000. A. M. Jensen, Fresno, consult. engr.

Connecticut

MERIDEN—The Miller Bros. Cutlery Co., 464 Pratt St., will soon award the contract for the construction of a 4-story, 50x90-ft. addition to present plant on Pratt St. Estimated cost, $50,000. W. T. Arnold, 105 Elm St., archt.

Illinois

CHICAGO—Darling & Co., 4201 South Ashland Ave., have awarded the contract for the construction of three buildings, including a 5-story, 97x100-ft. distillation plant, etc., to Stresenreuter Bros., 3020 South Halstead St. Estimated cost $225,000.

Iowa

CENTERVILLE—The city will soon award the contract for the construction of a sewage disposal plant, etc. R. O. Stephenson, city clk. M. G. Hall, engr.

Maine

ROCKLAND—The Rockland & Rockport Lime Corp. plans to rebuild lime plant which was recently destroyed by fire, entailing a loss of about $100,000.

Michigan

GREENVILLE—The Moore Plow & Implement Co. is in the market for gray iron foundry and pattern shop equipment.

HOWELL—The Howell Electric Motors Co. is in the market for brass foundry equipment.

Minnesota

ELLSWORTH—E. A. Meester, village recdr., will receive bids until March 26 for the construction of sanitary sewers, disposal works, including a disposal tank, sludge bed, etc. Estimated cost, $40,000. Druar & Smith, Globe Bldg., St. Paul, engrs.

New Jersey

HARRISON—Driver Harris Co., Middlesex St., is constructing a 3-story, 52x100-ft. building including an office, spooling and testing room, etc. G. A. Rickert, adv. mgr.

New Mexico

GAGE—Norman Welch, supt., plans to install a 50-ton concentration mill to handle fluorspar, in connection with its fluorspar mine here.

New York

BROOKLYN — Devoe - Reynolds, 460 Smith St., is having plans prepared for the construction of a 6-story, 55x175-ft. paint factory at Smith and Hamilton Sts., and is in the market for chemicals for the manufacture of paint. Fred A. Phelps, Union Bldg., Newark, N. J., archt.

PENN YAN—The city held an election March 16 to vote on $5,750 bonds to repair sewage disposal system.

SCHENECTADY—The General Electric Co., River Rd., plans to construct a 1-story, 206x600-ft. punch press shop on Central Ave. Estimated cost, $700,000.

North Dakota

CANDO—The town plans to construct a sewage disposal plant. Estimated cost, $60,000. Atkinson and Hall, Devils Lake, engrs.

MINOT—The city has awarded the contract for the construction of a sewer system and sewage disposal plant, to G. W. Kewper, Minot. Estimated cost, $205,000.

Ohio

AKRON—The S. & O. Engraving Co., 330 South High St., is having plans prepared for the construction of a 2-story, 40x150-ft. office and laboratory building on High St. Harpster & Bliss, Nantucket Bldg., archts. Mayer & Valentine, Bangor Bldg., Cleveland, engrs.

CINCINNATI — The Standard Silicate Co. has purchased a 24-acre site on Paddock Rd. and plans to construct a factory on same. Estimated cost, $750,000.

CLEVELAND—The Buckeye Brass Co., 6410 Hawthorne Ave., has awarded the contract for the construction of a 1-story, 30x110-ft. foundry, 75x75-ft. furnace room and an 18x35-ft. wash-room on Ashland Rd., to Gometz & Neshkes, 2361 East 61st St. Estimated cost, $75,000.

NEW PHILADELPHIA—The Weiss McClung Co. plans to build a 1- and 3-story factory for the manufacture of rubber. Estimated cost, $300,000. W. F. Ferguson Co., 1900 Euclid Ave., Cleveland, engr.

Oklahoma

RED FORK—The Sunlight Carbon Co. has purchased an 8-acre site near here and plans to build a carbon factory for the manufacture of lamps, dry cells, lamp black, etc., on same. Estimated cost, $100,000.

Pennsylvania

MILLERSBURG—The Alvord Reamer & Tool Co. has awarded the contract for the construction of a 40x60-ft. addition to plant, to H. Helwig, Millersburg. Address W. S. Umberger.

PHILADELPHIA—The Trenton Crockery Co., 106 North 2nd St., has awarded the contract for altering the 5-story, 120x195-ft. factory, to Smith-Hardican, 1606 Cherry St. Estimated cost, $10,000.

West Virginia

WESTMORELAND (Huntington P. O.) —The West Virginia Glass Co., Huntington, plans to build two additional units to its plant, here.

Wisconsin

MANITOWOC — The Aluminum Goods Mfg. Co., 15th and Franklin Sts., had preliminary plans prepared for the construction of a 2-story, 60x350-ft. rolling mill on Main St. Estimated cost, $500,000. Lockwood, Greene & Co., South Dearborn St., Chicago, engrs.

Ontario

SAULT STE. MARIE—The Natl. Electric Products Ltd., 83 Church St., Toronto, plans to build a 1-story factory for the manufacture of liquid oxygen. Estimated cost, $25,000.

SUDBURY—The High School Bd. is having plans prepared for the construction of a 2- or 3-story high school. Equipment for chemical and physical laboratories will be installed in same. Estimated cost, $200,000. P. J. O'Gorman, archt.

WOODSTOCK—John Morrison, city clk., will receive bids until March 24 for the construction of a 1,500,000-gal. sewage disposal plant, Imhoff style, etc. F. J. Ure & Son, engrs.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will hold a meeting on March 26, the subject of which is "Peace Uses for War Products."

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theatre: "Helium," Monday, March 29, at 4 P.M., Dr. R. B. Moore, chief chemist, U. S. Bureau of Mines (*Lantern*); "Romance of Leather Making," Tuesday, April 13, at 4 P.M., E. A. Brand (*Lantern*); "Water Supply and Drainage in War Cantonments," Wednesday, April 21, at 4 P.M., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers Process), Thursday, April 29, at 4 P.M., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 P.M., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 P.M., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern*).

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MINING SOCIETY OF NOVA SCOTIA has planned a meeting for May 4 and 5 which will be held in Glace Bay.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE PENNSYLVANIA SAFETY CONGRESS for 1920 will be held at Harrisburg, Pa., March 21 to 25 inclusive.

THE SOCIETY OF INDUSTRIAL ENGINEERS will hold its national spring convention March 24 to 26 at the Bellevue-Stratford Hotel, Philadelphia.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Are Executives to Join The Labor Turnover?

INDUSTRIAL unrest is ordinarily thought of as being perpetually epidemic in the "submerged tenth," and sporadic among laborers, mechanics and craftsmen. We hear much about this unrest—the former class furnishes fields where the police department's bomb-squad works, while organized labor furnishes the ever-present strikes and endless negotiations which receive such wide publicity.

Only since the profiteer has waxed fat has it dawned upon many that uneasiness is spreading wide among the men who wear white collars and work with their heads or nerves rather than their muscles. Only recently has it been recognized that a ferment is working among those conservative citizens who are often likened by the orator to the ballast of the ship of state, or other important, nice-sounding things. Whereas it was easy to see that large horizontal increases in wages had wiped out the differential which attracted the best workmen to the places demanding the most skill, effort and trust, it has only recently dawned upon many employers that there is a tremendous turnover in their staffs of clerks, technical men and unorganized skilled artisans. They seem to be driven from one place to another, more or less against their instincts, but really driven in the hope that their salary may somehow become larger so as more nearly to cover their necessities and leave a little for play and thrift.

But now it is going even higher up. As but one instance, general foremen in railway shops have had their salaries raised up to $300 a month, yet master mechanics, with very much greater responsibilities, still get unchanged their $325—by no means enough for a good executive under the present range in prices. More than a few of the faithful superintendents are wondering whether a period of service extending over their whole working years, a time in which they gave ungrudgingly the best there was in them to the untold profit of their employing corporation, is going to leave them poor at the finish. A director or manager is indeed blind if he can view the spectacle of common labor receiving two to three times what it got before the war, and the prices of all commodities correspondingly up, and yet assume that the wholly unusual men who are responsible for the success of the business are not going to be restive under the same old salary plus a 10 per cent bonus and with an occasional bouquet.

Under such circumstances nothing less is to be expected than that the most energetic men will leave their old positions and join the restive ranks which form the labor turnover. Expensive as the turnover is among the working force, it must be ruinous if it gets to the executives. BABSON, the statistician, was timely in his recent warning to stand-pat business to 'ware the new concern, which is recruiting talent among those who have already made good elsewhere. While we believe (more from that hope which springs eternal than from hard experience with the price-boosting activities of those who sell things) that the peak of high prices has passed, still that is no reason for further delaying that impluse to raise the salaries to where they were before the war. Then watch the efficiency curve!

Do We Need Immigration?

AGENCIES that are engaged in studying the labor problem in the United States are making public facts and figures that must give pause to executives in those industries in which a steady and uniform supply of labor is a vital factor. The chemical industries are not so much dependent on labor, perhaps, as are the metal industries, and yet when there is an actual shortage of manpower in the country as a whole, all industry must be affected. It requires no fine calculation to prove that there is an actual shortage of manpower in the United States, to say nothing of having a reserve that can be called upon in emergency. The steel industry, the railways, the telephone companies, the mills, factories and mines of the country are suffering from an acute shortage of workers; and to a large extent that shortage is in labor that formerly was supplied by immigrants from foreign countries. Nor is the shortage in unskilled labor alone, as a glance at the "help wanted" advertisements in the daily papers will attest. One authority has estimated that $30,000,000 was spent in 1919 for such advertisements in the United States alone—an eloquent testimonial to the competitive conditions that drove employers to extremity in hiring their neighbors' employees.

Labor leaders may assert that this is a desirable condition as far as the worker is concerned, for now there are more jobs than workmen. For general prosperity and healthful industry, however, the doctrine is as fallacious as the converse that there should be a great excess of laborers so that industry might bid the labor market down. Somewhere between lies the happy medium, with a sufficient reserve in manpower to meet emergencies. All of the capital in the country is not always profitably employed; no more is all of the labor likely to be. It is equally fallacious to assume that production is the only item to be considered, for while a labor shortage may enhance the value of a job, the market for the product is diminished by the reduced number of consumers. To put it concretely, if the labor resources of the United States have been reduced in recent years by 4,000,000 immigrants who normally would have come to this country if the

war had not intervened, we are not only short of their productive effort in industry but we lack the market for the consumption of commodities that those 4,000,000 men and their 2,000,000 women and children would have required. Add to this definite shortage of labor the loss in production due to strikes and the slackening in the productive effort of the average workman, and we have all the elements of a situation calling for study and an intelligent solution.

How shall we escape from this *cul de sac*? The Inter-Racial Council which has been recently organized, representing more than 450 industrial establishments, is of the opinion that the only way out is to adopt a plan of systematic and regulated immigration. They believe that immigration is more of an industrial problem than one of politics, and that a study should be made of its ethnical phases in order to encourage immigration of those races most easily assimilated and best adapted to our industrial needs. Their remedy comprises three elements: selection of immigration at the source, supervision of its distribution on its arrival, and adequate steps to assimilate and Americanize immigrants instead of leaving them to shift for themselves.

The program appeals to us as worthy of support. At present there is little discrimination in regard to the first two items. Immigrants come from practically the four quarters of the globe, and few are denied entrance. In the past the stream of immigration has flowed into this country at a few ports, and like the delta of a great river has spread out over a comparatively small and already congested area. As for assimilation and Americanization, the efforts have been largely local and in some cases spasmodic, although all that has been done is praiseworthy. What is needed is a co-ordinated plan that will consider the type and quality of the immigrant, his place in this country after he arrives, and finally a definite effort to accustom him to our institutions and make an American out of him. Immigration is needed to avert a continuous shortage of manpower, but it must be regulated and not be allowed to proceed promiscuously.

Why Not Export Helium?

IT HAS been proposed, apparently in all seriousness, that we should establish an embargo upon the export of helium from the United States, in order to prevent foreign powers from accumulating a reserve supply for balloon-gas uses. We doubt very much whether this particular embargo will be given much serious consideration, but the principle involved in such matters should engage our most careful and serious attention.

Any natural resource of limited quantity that would be quickly exhausted and our own supplies thereby curtailed through export should be considered as being in a different class from materials such as helium which are being wasted unless developed and used currently. Helium is procured exclusively from the natural-gas supplies which are being developed and used for domestic or industrial purposes without regard to the helium content. If by maintaining a foreign market in such material we are enabled to exploit profitably this resource and develop the art of its recovery and handling to a satisfactory commercial state, we are attaining a very desirable position. Moreover, this development and industrial advantage would be fostered largely at the expense of the foreign purchaser, and thus our industrial independence would be established with small cost to us.

There is little need to fear that helium or any other similar commodity difficult to store can be accumulated for use to our subsequent detriment. It does not lend itself to storage in quantity except at prohibitive expense. Thus, it is reasonable to assume that not more than a current supply will be maintained by purchasers abroad.

On the other hand, we should not be content to sell all of this material abroad, for if we do we may find ourselves in the unenviable position of knowing how to prepare a material but not knowing how to use it effectively. We should certainly hope to continue in this country a reasonable amount of industrial application in aircraft work and any other lines that may find this gas commercially applicable, so that we may keep pace with foreign development. Beyond this, however, we see no reason why the greatest facility for exporting such a commodity should not be afforded our industries.

The principles thus discussed apply in many other cases, though perhaps not as fully or as strikingly as to helium. It is worth while, therefore, to stop long enough in our consideration of international relations regarding each mineral or other natural resource, and think clearly as to whether or not continued production for export as well as continued development of the arts or application are receiving proper encouragement within as well as without our boundaries.

Empirical Equations in Engineering Calculations

MOST, if not all, the formulas of physics and physical chemistry are in the primitive stages of a process of evolution. For example, take as a typical case the gas laws of BOYLE (MARIOTTE) and CHARLES GAY-LUSSAC), which form the very foundation of the study of not only gas phases but solutes as well. Later AMAGAT made a classical investigation in which he demonstrated that BOYLE'S premise that PV is constant for any given temperature is very inaccurate. Some time prior to AMAGAT'S publication of his nitrogen, hydrogen, ethylene and carbon dioxide $PV:P$ charts, VAN DER WAALS deduced a new gas equation, containing correction constants characteristic of individual gases. The generality of the VAN DER WAALS equation is only apparent and, not having great mathematical flexibility, it has not proved adaptable to a wide range of determined results in calculations to which it has been applied. While CLAUSIUS, DIETERICI and several others have devised more flexible mathematical equations, they have not solved the problem satisfactorily for the very simple reason that the premises they make are inaccurate, incomplete, or both.

In the case of steam, REGNAULT, BROCH, PEABODY, HENNING and many others have devised or revised the various empirical steam equations in PT that have been proposed since 1847. All these have, however, been too complicated to get into current engineering use. This, of course, is due to the fact that both the steam charts and tables are much more convenient.

There are cases in engineering where tables cannot be satisfactorily devised and empirical equations must be used. An excellent illustration is afforded of this

in the investigation of heat conductivity by GEORGE A. RICHTER, to whose paper on Double Pipe Heat Interchangers, published in this issue, the attention of the reader is directed. Mr. RICHTER has demonstrated the importance of film velocity, which has hitherto not been considered a factor of much weight. Problems of design require reliable guides in the form of tables, charts or equations of direct and specific applicability. To get this, theory has to take orders from an empirical superior. Deductions must be made on assumptions that have proved to be workable both forward and backward. Good empirical equations have an excellent qualification for workaday use by being based on data rather than a skeleton of simplified assumptions. The engineer is tending to make more use of them in his calculations and in time should derive better general equations than have hitherto been in vogue in theoretical science.

How Is an Invention Invented?

LAYING down rules whereby an invention may be conceived is as hopeless a task as demonstrating by pure reason the existence (or non-existence) of GOD, Immortality, or the Infinite—which if we wanted to digress might all be argued to be the same thing. Pursuing the original thought, however, scientists are generally as different in their mental processes from inventors as philosophers are from theologians in this principal respect: Scientists and philosophers reach their conclusions by a skillfully constructed train of thoughts proceeding from cause to effect, while inventors and theologians arrive at their destination by an exercise of intuition.

This is probably most apparent in various aspects of religion. The Infinite evidently cannot be comprehended by the finite mind; It must be accepted meekly as an act of faith. Intuition may not so clearly be the main characteristic of an inventor. But if a scientist (bred in the bone) and an inventor (by divine right) both start from a certain point and travel in a certain direction they will proceed side by side closely in step until they reach a wide chasm, across which lies their goal. On the edge of this abyss the scientist sits down and starts to think. The inventor, however, lifts his eyes from the abyss, and seeing his destination on the far side, arrives there with one stupendous leap. That is to say, his leap is long enough if he is a successful inventor; others land just short of the farther bank and drop into oblivion!

And a curious thing about it is, that after the scientist sits and ponders and builds a substantial bridge of thought across the gap, he ultimately arrives at the same destination. But it is sometimes a long and discouraging task interrupted by as many false starts and failures as bridging the St. Lawrence. Meantime, if he ask his inventor friend how he did it, the inventor (almost prophet) speciously exhibits a phantom bridge as unsubstantial as a monkey-span across the great gray-green, greasy Limpopo. And the surest way for scientist and inventor to become estranged is for the former to point out the perfectly obvious faulty links and actual gaps in the chain of argument. As a parting shot, the prophet will exclaim against the obtuseness of men who are not awed by the unusual, saying: "Why are you so blind that you can't see it is thus and so?" Trying to justify a fact is so obviously foolish when you know it exists!

Therefore it is rather futile to give instructions to inventors who will find those real epoch-making things yet hidden far out into the dark unknown. But as a matter of fact, only an infinitesimal number of inventions belong to this class. The rest are merely adaptations of known principles, or an arrival at a given point in well-mapped territory by a less devious route. With such utilitarian things most modern seekers are concerned.

Perhaps the principal rule to adopt would be: Don't become discouraged because others have tried and failed. A sufficiently minute search through the literature would doubtless reveal at least one reason why any given scheme would be almost foolish. One or more men may have actually recorded failures in attempting the same path you plan to follow. But it would be as bad to turn back because some one else had not successfully traveled the route as it would to abandon the expedition in discouragement on arriving at the first obstacle. Still, don't become discouraged at the wrecks along the way!

A case in point is the recent development of a commercial process for electrolytic white lead by KREJCI and his associates. Electrolytic white lead is no new thing, as the *Transactions* of the American Electrochemical Society will bear witness. It had never been taken beyond the experimental stage, however, for a variety of reasons, but good practical technology (otherwise known as common sense) eventually solved the larger applications. Yet these men are frank enough to say that had they known of the failures of the earlier experimenters *before* their successful attempt instead of after, it is doubtful whether the trial would have been made.

A second rule follows from the principal one. If you are acquainted with the former work, and can see that it has all split upon one rock, rearrange the attack so as to turn the obstacle into a pronounced advantage.

The late WILLIAM THUM was fond of pointing out how this was accomplished in his now almost universally-used process for parting gold and silver. In all former experimentation it had been found impossible to refine gold bullion successfully in a tank, because the silver deposited from nitric acid solution would always (no matter what dodges were tried) deposit in a discontinuous mass of needles, which played havoc with electrical conditions and would not adhere to the vertical anodes. Yet, and it seems so simple that it took one of those flashes of genius to discover it, if the bottom of the tank were made the anode, the insurmountable difficulty of a non-coherent deposit became the chief advantage. Thus, in placing the impure cathode bars horizontally in the tanks, the loose crystals of pure silver collecting in quantity under the diaphragm at the bottom of the tank could be shoveled out quite easily.

Another simple illustration of the second point which comes to mind is concerned with matte casting. Those lead-plant men, who are used to casting matte buttons, know the difficulty and expense involved in breaking up the thick, tough slabs, to say nothing of the explosion risk when a partially-solidified mass breaks in handling. Yet if the liquid matte be purposely bled from the interior of such a button, the remaining shell will be safe to handle and will break with the utmost ease into the correct-sized material for re-charging.

Instances might be uselessly multiplied. After all is said and done, inspiration cannot be explained! But in directing it, the best captain is sound theoretical groundwork, and the best lieutenant is wholesome common sense.

Readers' Views and Comments

A Study of the Lime-Soda Ash Water-Softening Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—Having spent several years specializing on the purification of water for industrial purposes, the writer found the article by Max H. Herrle and Francis M. Gleeson, "A Study of the Lime-Soda Ash Water-Softening Process" (appearing in the Feb. 11, 1920, issue of CHEMICAL & METALLURGICAL ENGINEERING), quite interesting from a strictly laboratory standpoint, since they embody certain experiments the writer has never duplicated.

It would appear quite doubtful, however, if the authors of this article have any wide experience or knowledge of conditions met with in the evaporation of water for steam; for the reason that they fall into errors in drawing conclusions which indicate that the article is the product of analytical chemists without engineering experience.

In the first place, they divide the subject of water purification into three classes—distillation, filtration, and chemical purification by precipitation. Did they, in elaborating on these three classes, allow filtration and chemical purification by precipitation great enough latitude, this would be correct, but they limit filtration to the removal of suspended matter, and chemical purification to the use of some form of the lime-soda ash, the caustic soda, or the lime-barium water softener.

This excludes two widely used and well recognized methods of water purification—the zeolite method of water softening, and the use of boiler compounds.

Strictly speaking, the zeolite method of water softening is a filtration method, and for the benefit of Messrs. Herrle and Gleeson and any others who may not be acquainted with this method, I will give a very brief explanation of the process. A zeolite (as exemplified by Refinite, Permutit and Decalso) is a hydrated silicate of aluminum containing a large amount of sodium in a loosely bound condition. By what is known as the law of mass action, this sodium is exchanged for the calcium and magnesium in water percolated through a bed of the zeolite, and the water leaves the filter bed carrying only a trace of calcium and magnesium salts. Just as an aside, this is the only method of water purification known—aside from distillation itself—which *can* give water that will approximate the theoretical 0.0 deg. hardness.

Some may object to the classification of boiler compounds as a method of purifying water, and with justice. The writer, however, knows of at least one company which, by fitting the compound to the water in a scientific manner, really justifies the terminology of water purification. Since any scientifically prepared boiler compound achieves its object by the precipitation of scale-forming substances inside the boiler, it might properly come under their third classification, but it would strain the limits of this classification, as given by the authors.

The primary object of this letter, however, is to point out some erroneous conclusions and the effects to be anticipated should they be allowed to effect the principles under which the water-softening plant is operated.

Their summarization of results from experiments with soda ash alone reads as follows:

"Sufficient soda ash should be added so that a slight excess of this reagent remains after the chemical action between it and the water has been completed. The excess will have no effect upon the hardness and but little effect on the alkalinity, so that the engineer need have no fear of its presence. This excess will prove of great value in case the raw water varies in initial hardness, as such small fluctuations can be readily cared for by this reagent."

This conclusion is diametrically opposed to the best water-softening practice. The standard practice calls for slightly less soda ash than is sufficient to carry the reactions to completion, and tests on a properly treated water will conform to the following proportions:

The hardness shall be slightly less than the total alkalinity. The caustic alkalinity shall be slightly more than half, but never more than two-thirds of the total alkalinity. Hardness to be determined by titration against a soap solution standardized to read in grains per gallon calcium carbonate equivalent. Total alkalinity to be determined by titration with methyl orange as an indicator. Caustic alkalinity to be determined by titration using phenolphthalein as an indicator. Both caustic and total alkalinity to be reported in grains per gallon calcium carbonate equivalent.

In the laboratory a slight excess over the theoretical amount of soda ash is necessary to carry the precipitation of the calcium salts to completion, but for best results in a boiler this excess is not only unnecessary, but is positively dangerous.

The purpose of softening water for boiler use is the prevention of scale, and under boiler conditions the precipitation is completed with less soda ash than the amount necessary to complete precipitation in the water softener. When this precipitation is completed within the boiler, scale is not formed, but the precipitate settles to the bottom of the boiler as a sludge or mud and is disposed of in the blowoff.

All sulphates, chlorides and nitrates present in the raw water remain in the treated water in the form of the corresponding sodium salt. Of these, the sulphate and nitrate (the latter is very rarely present) show a marked tendency to cause foaming and priming with relatively small concentration. This tendency is greatly increased by the presence of soda ash; with the addition of greater quantities of soda ash, it increases in a double ratio. Hence, while—as pointed out by Messrs. Herrle and Gleeson—the addition of an excess of soda ash will not cause the hardness to rise, as is the case with lime, it does add enormously to the danger of foaming and priming, and a thin film of scale which might be caused by an insufficient amount of soda ash in the treatment would cause far less trouble than would the carrying over of water with the steam, not to mention the fact that it might endanger the lives of the engine room attendants.

Turning now to the question of minimum hardness obtainable. By no precipitation process is the theoretical minimum of 0.0 deg. possible of achievement. The minimum hardness possible with any cold water lime-soda ash treatment is approximately 1.66 g. per gal.

(It is not possible to precipitate down to an amount smaller than the solubility of the precipitate. Calcium carbonate has a solubility of 0.76 g. per gal., magnesium hydrate a solubility of 0.53 g. per gal., or calculated to the calcium carbonate equivalent, a solubility of 0.90 g. per gal., a total of 1.66 g. per gal. calcium carbonate equivalent.)

The soap solution used by the authors of the article under discussion was evidently standardized to some odd factor, for with the presence by analysis of 1.52 g. calcium carbonate, and 0.39 g. magnesium hydrate (0.67 g. calcium carbonate equivalent)—a total of 2.19 g. per gal. of hardness—they report 0.50 deg. of hardness.

The explanation they give, that "the theoretical hardness of 0.0 deg. is not obtainable, being probably due to the small sample of water originally treated," does not argue a wide experience in the water-softening field, nor does it indicate a deep knowledge of the chemistry of water softening. It is well known to water-softening experts that it is possible to secure better results with laboratory-sized samples and with laboratory methods of chemical measurement than can be obtained in industrial water softeners. It is also well known that the "theoretical hardness of 0.0 deg." is impossible of attainment by any method other than distillation, for this would require the total absence of all calcium, magnesium and iron salts. Zeolite softeners sometimes approximate a zero hardness, but they never in fact quite reach it.

The statement, therefore, that "In the water-softening system in operation at our plant it is nothing unusual to obtain a hardness of 0.0 deg." is so palpably impossible that it throws a strong element of doubt upon any conclusion reached in the entire article.

Wood Alcohol as a Beverage

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the *Literary Digest* of Feb. 14, I note a review of an article in your publication for Jan. 21, in which is stated that some chemists have asked the Commissioner of Internal Revenue to change the name of wood alcohol to "woodine." I thought it might interest you to know that a short time ago I wrote one of our legislators from this state, the Hon. Carlos P. Bee, suggesting that he endeavor to have a law enacted requiring manufacturers and dealers to label, list and sell wood alcohol as wood naphtha. This will classify the real nature and use, and prevent so many unfortunate mistakes being made by people confusing it with the alcohol of intoxicating liquors.

The whole source of the use of wood alcohol in beverages, medicines, etc., was in the fact that its very name was misleading, and the only way to eradicate the evil and to combat its mistaken use is to inaugurate a campaign of widespread publicity as to its real nature and use, and the most effective means of doing this is to give it a name that classifies its real use. As a pharmacist and chemist I have studied our methods of preventing the uninformed people from misusing wood alcohol and I have come to the conclusion that the only logical course is to have laws passed making it compulsory with dealers and manufacturers to label it "wood naphtha."

O. W. NOLAN.
San Antonio, Tex.

Spring Meeting of the American Electrochemical Society

THE spring meeting of the American Electrochemical Society will be held in Boston April 7 to 10 inclusive. There will be a meeting of the board of directors Wednesday evening, April 7. The following program is announced:

THURSDAY, APRIL 8

The annual business meeting will be held in the morning and the retiring president, Wilder D. Bancroft, will deliver an address on "Contact Catalysis."

Symposium on Colloid Chemistry:

W. D. Bancroft, "Colloid Chemistry and Electrochemistry."

W. A. Deane, "Settling Problems."

T. R. Briggs and W. J. Bartlett, "The Adsorption of Arsenious Oxide by Metastannic Acid and the Purification of Spent Electrolyte."

G. A. Hulett, "Graphitic Acid, a Colloidal Oxide of Carbon."

A. C. Fieldner, "Determination of Graphitic Carbon."

William C. Moore, "Selective Adsorption by Bacillus Pyocyaneus."

Guy Clinton, "A Criticism of Kohlrausch's Law of the Conductivity of Solutions."

H. D. Holler and L. M. Ritchie, "Hydrogen Ion Concentration in Dry Cells."

D. A. MacInnes, "The Reactions of the Lead Accumulator."

William Roy Mott, "Arc Images in Chemical Analysis."

FRIDAY, APRIL 9

Joint meeting with the American Institute of Electrical Engineers, W. D. Bancroft presiding.

Symposium (A.M.) on Electrically Produced Alloys:

H. E. Howe, "Fundamental Problems in Alloys Research."

R. J. Anderson, "Recent Developments in the Ferro-Alloy Industry."

C. B. Gibson, "The Manufacture of Ferro-Alloys in the Electric Furnace."

B. D. Saklatwalla, "Ferrovanadium."

Elwood Haynes, "Stellite."

F. A. Raven, "Properties of Ferrosilicon."

E. S. Bardwell, "Ferromanganese."

R. C. McKenna, "The Manufacture of High-Speed Steel in the Electric Furnace."

Alcan Hirsch, "Ferrocerium."

Theodore Swann, "Ferrozirconium."

B. G. Klugh, "Ferrophosphorus."

R. M. Major, "Nichrome and Other Special Alloys."

T. D. Yensen, "Electric Properties of Nickel-Iron Alloys."

M. A. Hunter, "Electrical Properties of Titanium Alloys."

C. F. Harding, "Nitrogen Fixation by the Silent Discharge."

Symposium (8:30 P.M.) on Power for Electrochemical Industries, President C. Townley of the A.I.E.E. presiding:

John L. Harper, "Power for Electrochemical Plants."

John A. Seede, "Automatic Control of Arc Furnace Electrodes."

H. A. Winne, "Reactors for Electric Furnace Circuits."

C. A. Winder, "Economies of the Power Situation."

E. A. Wilcox, "Electric Furnace Power From the Standpoint of the Central Station."

H. L. Hess, "The Electric Furnace and the Central Station."

C. T. Maynard, "Location of a New England Electrochemical Plant."

F. F. Fowler, "Water Powers of the Pacific Coast."

J. W. Beckman, "Power Development in Scandinavia."

W. G. Berlin, "Power Problems From the Standpoint of the Furnace Operator."

SATURDAY MORNING AT HARVARD UNIVERSITY

J. W. Richards, "The Soderberg Self-Baking Continuous Electrode."

C. A. Jeller, "Synthetic Electric Furnace Pig Iron."

Philip B. Short, "Step Induction Regulators for Electric Furnaces."

Clarence J. West, "The Electric Furnace as Applied to Metallurgy."

H. M. St. John, "The Electric Brass Furnace; Its Evolution."

L. B. Lindemuth, "The Electric Furnace in Iron and Steel Metallurgy."

Edward F. Kern, "Reduction of Manganiferous Silicate Slags."

INDUSTRIAL EXCURSIONS

Trips will be made to the Lynn Works of the General Electric Co., on Friday at 1:30 P.M., and to the Huff Electrostatic Separator Co., on Saturday afternoon.

An informal subscription dinner will be held Friday evening at the Copley-Plaza.

Spring Meeting of American Chemical Society

The following tentative general program has been prepared for the St. Louis meeting of the American Chemical Society, April 12 to 16.

MONDAY, APRIL 12

4 p.m., Council meeting.
7.30 p.m., Council dinner at the University Club.

TUESDAY, APRIL 13

10 a.m., General meeting, Hotel Statler.
Address of welcome, Mayor Henry W. Kiel.
Response, Dr. W. A. Noyes, president, A. C. S.
Address, the Hon. E. P. Costigan, Tariff Commissioner, "Chemical Industry and Legislation."
Address, Dr. Charles H. Herty, editor, "Victory and Its Responsibilities."
2 p.m., Hotel Statler, general meeting.
J. H. Hildebrand, "The Prediction of Solubility."
Victor Lenher, "Selenium Oxychloride a Neglected Inorganic Solvent."
E. T. Wherry, "Studying Plant Distribution With Hydrogen Ion Indicators."
Three additional general papers to be announced.
8 p.m., Liederkrantz Club. Smoker for men.
8 p.m., Theater party for ladies.

WEDNESDAY, APRIL 14

9 a.m., Hotel Statler, divisional meetings.
2 p.m., Hotel Statler, divisional meetings.
8 p.m., Central High School. Public address. Speaker and subject will appear in final program.

THURSDAY, APRIL 15

9 a.m., Hotel Statler, divisional meetings.
2 p.m., Excursions to Laclede Gas Works, Monsanto Chemical Works, East St. Louis plant, and Laclede-Christy Clay Products plant. Automobile tour for ladies to parks, Art Museum, Washington University, Missouri Botanical Garden, and tea at Bevo Mill.
8 p.m., Hotel Statler, subscription banquet.

FRIDAY, APRIL 16

9 a.m., Excursion to Standard Oil Refinery, Wood River, Ill., and Illinois Glass Co., Alton, Ill.

DIVISIONAL MEETINGS

The usual meetings will be held by all of the divisions except the Fertilizer Division. The Division of Industrial and Engineering Chemistry will hold a symposium on Cellulose Chemistry. The Sections of Leather Chemistry and Sugar Chemistry will meet for the first time. The Division of Physical and Inorganic Chemistry will devote a half day to a "Colloid Symposium." Programs for the divisional meetings are in process of preparation and details will be announced later.

EDWARD MALLINCKRODT, SR.
Honorary Chairman, Executive Committee

Meeting of Electric Furnace Association

Coincident with the meetings of the American Institute of Electrical Engineers and the American Electrochemical Society, there will be a meeting of the Electric Furnace Association, in Boston, April 8 to 10. The annual election and business meeting will be held on April 8. On one other day there will be a session on the proper training of operators of electric furnaces. The Association will meet with the two other societies mentioned above during their discussions on Electrically Produced Alloys and Power for Electrochemical Purposes. The combined program will be of particular interest to electric-furnace operators, inasmuch as subjects of such vital importance to the industry will be discussed. Indications are that there will be a good attendance of electric-furnace men at these sessions and that very excellent papers will be presented. During the meeting the headquarters of the Electric Furnace Association will be at the Copley-Plaza Hotel.

The Dye Industry of Great Britain

During the last year there has been considerable criticism by users of the range of dyes available either from British dye-manufacturing works or from the supplies which have been imported from Germany in fulfillment of the terms of the treaty of peace. These criticisms appear to arise from a fear that the British textile trade may be placed at a disadvantage in the markets of the world.

It is claimed that 80 per cent of the dyes now being used in Great Britain are of home production, but the total quantity available, even of the common grades, does not appear to be sufficient for the needs of the textile manufacturers, to say nothing of the high-class dyes. Prior to the war the highly organized German dye combine maintained in Great Britain large stocks of dyes from which immediate deliveries could be made. At the present time the British dye industry is making strenuous efforts to meet the demand, but is not able to keep a stock on hand for immediate delivery, as the dyes are sold even in advance of production and shipped direct from the plant.

For several months past there has been a great deal of anxiety on the part of dye manufacturers as to the future of the British dye industry, owing to the fact that certain high-class dyes which are very much needed in the textile and other trades are not produced in Great Britain. The fear of the possibility of the removal of the restrictions on the importation of German dyestuffs, or the necessity of the government taking some action to secure for the trade these high-class dyes, seems well founded, from the fact that it is now announced that a committee, representing all the industries using dyestuffs, is now in Germany for the purpose of purchasing such dyes as are required by the British consumers and is authorized to buy up to £2,000,000 worth of fine dyes.

The British Government is reported as taking no part in the financial arrangements, but has granted the necessary facilities for this committee to make these purchases. Any dyes that the committee may secure will be in addition to the 1,500 tons to which the British users are entitled under the reparation clause of the Peace Treaty.

Government Kelp Plant to Continue Operations

The House of Representatives has approved an appropriation of $192,000 "for the completion, operation, and maintenance of the Government kelp plant at Summerland, Cal." The following conclusions of the Department of Agriculture specialists have apparantly had much to do in influencing the House to grant the appropriation in face of persistent efforts to eliminate or reduce the appropriation:

(1) Results to date show definitely that the successful outcome of experiments is assured that byproducts will be developed which will more than carry the production cost of potash. This will enable kelp potash, then, to come into the market where freight rates are not prohibitive, in competition with potash from any other source.

(2) With a successful outcome assured, it would be unwise to discontinue the work and lose the credit which is bound to accrue to the Government through the successful prosecution of a problem undertaken in the face of so much criticism and one advertised so widely by its opponents as illogical and uneconomical.

(3) Its continuation from now on will be at a very slight and decreasing expense to the public, the proceeds from this year's production probably being about enough to equal expenditures and those from next year's operation probably more than equaling expenditures. That the enterprise will be self-sustaining within a short period seems assured.

(4) It should be borne in mind that at the completion of the work, with the results anticipated, the plant will be on a profitable basis and could be put on the market as a going concern earning a profit, and would yield a price accordingly. If it is sold before all the facts are demonstrated it would have to be sold as junk, and as such would yield only about a third of what it would yield otherwise. If sold as a going concern, however, it would yield not less than $100,000.

It is easy to see, therefore, that if we keep going until the work is completed, the net profit to the Government will be greater than if the work were discontinued at the end of the present year.

(5) Since it has been demonstrated that not less than 500,000 tons per annum of raw kelp are available in the vicinity of Summerland, it is to be assumed that when it is demonstrated what profits are obtainable from the treatment of kelp by the process developed here plants will be established sufficient in capacity to utilize the raw material available. We may with confidence, therefore, look forward to the establishment ultimately of an industry in this part of the State of California which will yield the products obtainable from this quantity of kelp and of an annual value of over $7,000,000. This estimate does not take into consideration the equally large industry which may be founded additionally on the kelps of Puget Sound and Alaska. The profit to the public, therefore, from the successful outcome of these experiments seems to be beyond question, and certainly would seem to justify a continuation of the slight net expense to the public now being incurred in this work.

Bureau of Chemistry Appropriation

As reported to the Senate, the agricultural appropriation bill carries $1,393,591 for the Bureau of Chemistry. This is $72,000 more than the total of the appropriations allowed in the bill passed by the House.

The bulk of the increase was allowed on items providing funds for conducting the investigations relating to the application of chemistry to agriculture; for the work connected with the food and drug act and for the investigation of chemical problems relating to insecticides and fungicides. An increase also was allowed to the Bureau of Soils for that portion of its work having to do with chemical properties of soils. The appropriation for that purpose as recommended by the Senate committee is $25,610.

A fund of $36,840 is provided for exploration and investigation within the United States to determine possible sources of potash, nitrates and other natural fertilizers.

Forest Products Laboratory Appropriation

In the agricultural appropriation bill which has been reported out by the Senate committee, the appropriation to be used at the Madison (Wis.) Laboratory of the Forest Service is increased from $173,260, allowed by the House, to $223,260. This money is to be expended for investigations of methods for wood distillation and for the preservative treatment of timber; for timber testing and for testing of such woods as may require test to ascertain if they be suitable for making paper; for investigations and tests of foreign woods of commercial importance to industries in the United States and for other investigations and experiments; to promote economy in the use of forest products and for commercial demonstration of improved methods or processes in co-operation with individuals and companies.

Meeting of American Section, S. C. I.

On Friday, March 19, there was an unusually large attendance at the monthly meeting of the American Section of the Society of Chemical Industry at the Chemists' Club. Chairman Charles E. Sholes submitted the following nominations for officers, which were approved and ordered forwarded to London for final approval: Sumner R. Church, chairman; F. C. R. Hemingway, treasurer; Allen Rogers, secretary; committee: Charles E. Sholes, Ralph H. McKee, Wallace P. Cohoe, D. D. Jackson, H. G. Carrell.

The opening paper by Bruce Silver consisted mainly of slides gathered by the author in a recent tour through the American petroleum fields. Moving picture reels furnished by the Standard Oil Co. were used in conclusion, giving the audience an excellent mental picture of the industry.

Speaking on the subject of "The Manufacture of Rare Chemicals," Dr. C. E. Kenneth Mees reviewed the progress in this country in the manufacture of organic reagents required for industrial and university research laboratories. Chemicals of this class were imported almost exclusively before the war and the shutting off of imports, coupled with the sudden development of the synthetic organic industries, created a situation which rapidly became acute. To meet the increasing demand, Dr. Derrick and later Dr. Roger Adams at the University of Illinois set some of the graduate students in organic chemistry to work on the problem during the summer vacation. The venture was so successful and the development so rapid that it soon became necessary for an industrial firm to take over the production of these small-scale products and also to engage in the purification for research work of certain of the technical organic chemicals which were beginning to appear on the market. This phase of the work was taken up by the Eastman Kodak Co., which now acts as distributing agent for these research chemicals. This requires the keeping of small stocks of a large number of chemicals, which means a large financial investment in proportion to the turnover. Thus, a $50,000 stock would be required for a turnover of about $20,000 a year. Over six hundred chemicals are now available and the list is being rapidly extended.

Much of the work is being done in an improvised laboratory which, judging from the view shown, has reached its productive limit. A larger laboratory will be established in the near future.

Senate Hearings on Fixed Nitrogen Corporation Bill

Senate hearings on the bill to establish the United States Fixed Nitrogen Corporation for the purpose of purchasing and operating the nitrate plants at Muscle Shoals were scheduled to begin before the Committee on Agriculture on March 22. The bill proposes the organization of a corporation, all the capital stock of which shall be owned by the Government. Evidence probably will be introduced to show that the plants should be operated and that such operation should be conducted by the Government through a special corporation rather than by private interests. Among those who may appear before the committee are Secretary Baker, George J. Roberts, Alfred H. White, Arthur B. Lamb, Colonel Burns, Colonel Joyes and Major Gaillard.

Investigation of Fuel-Oil Fire Hazards

Owing to widely divergent views as to the fairness of the tentative fuel oil regulations recently issued by the National Fire Protection Association, E. A. Barrier, chairman of the committee on inflammable liquids of that association, has deemed it advisable to institute immediately a thorough investigation throughout the fuel oil-consuming centers of the country and to gather first-hand information relative to the existing conditions prevalent with regard to fire protection and fire hazards.

Mr. Barrier has asked for the co-operation of the American Petroleum Institute in connection with this important subject. Therefore, it has been decided to engage the services of C. F. Reuter, who was formerly associated with the Tidewater Oil Co's engineering department, to represent the American Petroleum Institute and to accompany F. O. Aspinwall, who was appointed by the National Fire Protection Association to represent the interests of the insurance companies in this investigation.

Considerable significance is attached to the results of this investigation, which will probably cover a period of six weeks. Upon ascertaining the true condition as to fire hazards in the storage and use of fuel oil, it is hoped that the present regulations will be modified so as to possess nothing of a discriminatory character, yet at the same time to conform to established good practice in providing proper safeguards against the danger of fire and accident.

A Grant for Research

The American Pharmaceutical Association has available a sum amounting to about $450 which will be expended after Oct. 1, 1920, for the encouragement of research. This amount, either in full or fractions, will be awarded in such manner as will in the judgment of the association's research committee produce the greatest good to American pharmaceutical research. Investigators desiring financial aid in their work will communicate before May 1 with H. V. Arny, chairman A. Ph. A. research committee, 115 West 68th St., New York, giving their past record and outlining the particular line of work for which the grant is desired. The committee will give each application its careful attention and will make recommendations to the association at its meeting in Washington, May 3 to 8, 1920, when the award or awards will be made.

Revised Text of Federal Reserve Act Issued

A book containing the Federal Reserve act, revised to include all amendments to Dec. 24, 1919, has been issued by the National Bank of Commerce in New York. The volume is prepared for reference purposes, being fully indexed and provided with marginal annotations. Several of the amendments are particularly significant in connection with recent international developments affecting American banking, such as the Edge act and sections relating to the investment by national banks in foreign banking and financing corporations organized under Federal or state laws.

Platinum at Goodsprings, Nevada

The Boss mine at Goodsprings, Nev., which so far as known is the only lode mine on the continent in which platinum is found, shipped $22,365 worth of platinum-bearing ore during 1919.

Electrolytic Zinc Plant of the Judge Mining & Smelting Co.

A Description of the Treatment of Table and Jig Concentrates at Park City, Utah—Leaching—Purification of the Solution—Electrolytic Plant Installation and Operation—Power Consumed—Daily Production Capacity

By L. W. CHAPMAN

THE electrolytic zinc plant of the Judge Mining & Smelting Co., at Park City, Utah, is designed to treat concentrates obtained from a sulphide ore containing zinc, lead and silver. In their concentrator a lead concentrate and a zinc concentrate are obtained. The lead concentrate is shipped and smelted. The zinc concentrate is treated in the plant for the recovery of zinc and the zinc-plant residue is shipped and smelted for the recovery of the silver and lead. This briefly is an outline of the treatment of the ore. The removal in the mill of a large portion of the zinc from the ores produces a concentrate which can be economically smelted for the recovery of the lead and the silver. Previous to the construction of the electrolytic zinc plant a zinc concentrate had been obtained, which was sold to smelters.

Treatment of the Concentrate

The concentrate treated in the zinc plant contains about 38 per cent Zn, 3 to 5 per cent Pb, and 9 to 10 oz. Ag per ton, with small amounts of copper, cadmium, antimony, manganese and arsenic. Concentrates will average about 30 per cent sulphur and 8 per cent iron. Two grades of concentrates are delivered to the zinc plant—a table product and a jig product. These are kept separate, as the jig concentrate is too coarse to give satisfactory recovery of zinc without grinding. The jig product is dried in a cylindrical drier and ground in a Hardinge ball-mill to pass 60 mesh, this size being obtained without screening the product with the return of oversize to the mill. The table concentrate is somewhat coarser than the Hardinge mill product, about 20 per cent being retained on a 60-mesh screen.

Concentrates are roasted in a 25-ft. seven-hearth Wedge roaster which is fired on the sixth hearth by two coal-fired combustion chambers located at opposite ends of a diameter of the roaster. The seventh hearth is used to cool the calcine somewhat before being delivered to a Baker cooler. The roasting operation produces a calcine containing a relatively small amount of insoluble zinc ferrate, most of the insoluble zinc being present as sulphide. Details of the roasting operation, together with data obtained from experiments with this roaster have been published by C. A. Hansen.[1]

Method of Feeding

The product from the Hardinge mill is elevated by a bucket elevator and fed directly onto the top or drying hearth of the Wedge roaster by means of a belt conveyor. The table concentrates are also elevated by a bucket elevator, but are transferred to a feed hopper by a belt conveyor. Below the discharge spout of the feed hopper, at a distance of approximately 6 in., is a horizontal iron plate which prevents the flow of material from the hopper. Adjustable scrapers are bolted to each of the four rake arms of the drying hearth, and these scrape a definite amount of concentrates from the plate onto the hearth. This method of feeding is simple in detail and, although the amount of feed varies somewhat with the moisture content of the concentrate for a given set of scrapers, has operated satisfactorily.

Leaching Operation

Hot calcine flows by gravity from the roaster to a 5 x 12-ft. Baker cooler and from the cooler is transferred by a belt conveyor to a 400-ton storage bin. From this storage bin the calcine is elevated by a hoist to feed bins located above Pachuca tanks. There are two of these tanks, 14 ft. in diameter and 30 ft. in height, made of 3-in. redwood, each holding about 100 tons of solution. In conducting the leaching operation, the Pachucas are filled by gravity with acid electrolyte from storage tanks, together with sufficient sulphuric acid to make up for the loss sustained in neutralization and subsequent operations. The quantity of acid in the tank is determined from the analysis of the solution and an amount of calcine added which is calculated to reduce the acidity of the solution to about 3 g. H_2SO_4 per liter. In addition to zinc, small amounts of copper, cadmium and antimony are dissolved, and these must be removed before the solution is electrolized. As the first step in the purification process iron sulphate is added in the Pachucas sufficient to bring the iron contents to about 0.3 g. per liter. Pulverized lime rock is then added, with further agitation, and the remaining acid completely neutralized. This effects a complete precipitation of the iron and a practically complete precipitation of the antimony and arsenic. The leaching cycle requires from 8 to 10 hr.

Separation of the Sand and Slime

A centrifugal sand pump delivers the neutral pulp from the Pachucas to a No. 7 drag classifier. The sand from the classifier is delivered to a storage bin, the overflow to a 30-ft. Dorr thickener. The overflow of the Dorr is clear solution and is pumped to the purifying Pachucas, the spigot product from the Dorr is filtered and washed on an 11½ x 6-ft. Oliver filter. Oliver cake is delivered to a storage bin and the filtrate pumped to the purifying Pachuca containing the overflow from the Dorr.

The sand from the classifier and the filter cake contain the silver and lead from the concentrate together with the insoluble zinc and the soluble zinc which has not been removed by washing. This residue is shipped to smelters for the recovery of the silver and lead, as previously mentioned. The sand and slimes together are about half the bulk of the original concentrates. The slimes will carry 10 to 12 per cent zinc and the sand 15 to 20 per cent zinc, and together will assay about 12 per cent lead and 20 oz. silver per ton. It is not possible to

[1] "Electrolytic Zinc," by C. A. Hansen, *Trans.*, A. I. M. E., 1919, pp. 1,247-1,281.

wash the Oliver cake or the sands free from zinc sulphate, and a loss of both zinc and sulphuric acid results. This makes it necessary to add about 70 lb. of 50 deg. acid to the Pachucas for each ton of zinc produced.

Purification of the Solution

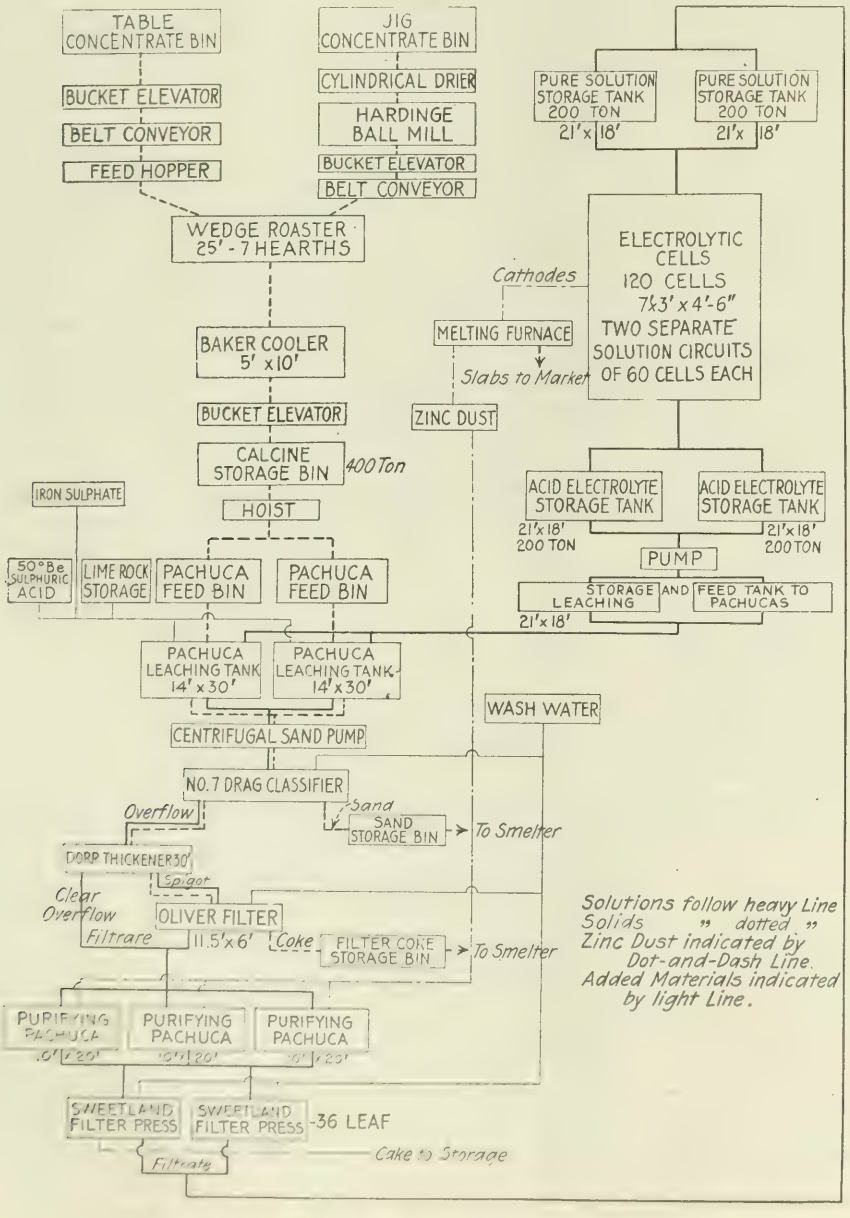
Purification of the solution is carried out in Pachucas by agitation with zinc dust. There are three of these tanks, 10 ft. in diameter x 20 ft. in height, made of 2-in. redwood, each having a capacity of about fifteen tons of solution. The Pachucas are filled with solution and the zinc dust is added in small batches. The quantity of zinc dust needed, the rate of addition and the time required for this operation are determined by the amount of impurities present in solution, but the operation is usually complete in from 20 to 30 min. In this operation all but minute traces of copper and cadmium and also any traces of antimony and arsenic that may have escaped precipitation simultaneously with the iron in the agitation tanks are removed.

Purified solution is filtered in either one of two Sweetland presses and the zinc-copper-cadmium sludge removed. These presses have 36 leaves, each 3½ ft. in diameter. Sweetland filter cake is stored, but a method for the recovery of the metals from the cake which contains 40 to 50 per cent Zn, 4 to 7 per cent Cu and 3 to 6 per cent Cd has recently been developed. The filtrate from the Sweetland presses is pumped to either of two 200-ton solution-storage tanks, from which it is run directly to the electrolytic cells as required. The average analysis of the purified solution is as follows, in grams per liter: Zn, 60; Cd, 0.004; Cu, 0.003; Mn, 0.4; Sb, 0.001; As, trace.

Electrolytic Cell Room

The electrolytic cell room contains 120 tanks. The tanks are arranged in cascade. Five tanks, which constitute a cascade, are placed end to end, the difference in elevation between tanks being 3 in. Two cascades of tanks are placed side by side, forming a bank of ten tanks. There are six of these banks across the cell room with aisles between and between the outside banks and the walls of the cell room. There are two of these sections of sixty tanks down the cell room with a wide aisle between the two sections and below the lower section providing ample room for stripping of cathodes.

Solution from the storage tanks is run into the head tank of each cascade, the flow being parallel throughout a section, each of which is provided with separate solution supply lines. Each section of sixty tanks also forms one electric circuit, the individual tanks of the section being connected in series.

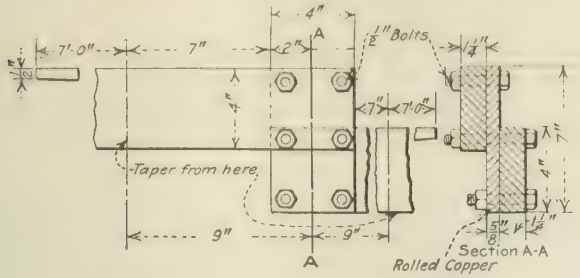


FLOW-SHEET, JUDGE ELECTROLYTIC ZINC PLANT

Design of the Tanks

The tanks are of standard design and are made from 2-in. redwood, and are 7 ft. long, 3 ft. wide and 4½ ft. deep. The overflow chute is made of chemical sheet-lead and is supported on a wooden bracket. The solution level in the tank is 2 in. below the top of the side walls. The chute clears the top of the next tank in the cascade by 1 in. and delivers the solution about 2 in. beyond the inner edge of this tank. Each tank is provided with a cooling coil installed in an upright position at the inlet end. The coil is made from 45 ft. of 1-in. chemical lead pipe, there being five 4-ft. loops to a coil. The solution is delivered to the head tank of the cascade from the storage tanks through iron pipes and the amount of flow controlled by gate valves. Provision is also made to run fresh solution to each tank if desired. The acid electrolyte from the lowest tank in the cascade flows into a lead pipe and thence by gravity to either of two 200-ton storage tanks located outside the building. From these tanks the solution is pumped by a centrifugal pump, with a closed bronze runner, to the supply tanks located above the agitating Pachucas and runs from these supply tanks to the Pachucas by gravity, thus completing the cycle.

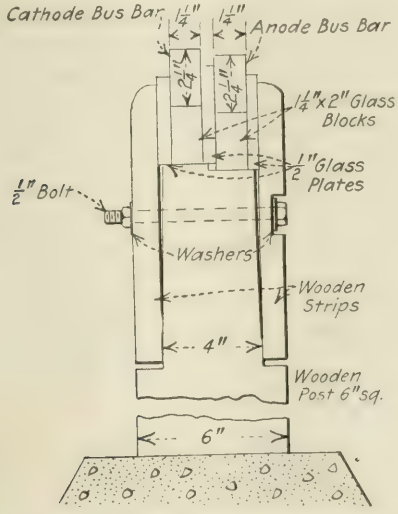
Anode and cathode busbars are both put on the side of the tank next to the aisle and are supported free from the tank by three 6 x 6-in. wooden posts carried down to separate concrete piers. Advantage is taken of the fact that the amount of current carried by the busbars decreases with each anode contact and increases with each cathode contact to effect a considerable saving of copper; the busbars are therefore tapered from ½ in. at the free end to 4 in. at the other, where connections are



DETAILS OF BUSBAR CONNECTION

made to the bus of the next tank. The maximum cross-section of the busbars is 1¼ in. x 4 in. They are made from rolled copper and supported with the long dimension of the cross-section vertical, the anode bus being on the inside next to the tank and ¼ in. lower than the cathode bus. The busbars are insulated from each other and from the guides of the wooden support by means of glass insulators ½ in. in thickness. The weight of the bus is carried upon glass blocks 1¼ in. in thickness.

The connection between busbars is made by means of a plate of rolled copper ⅝ x 4 in. in cross-section. This plate is bolted to the inside of the cathode bus and to the

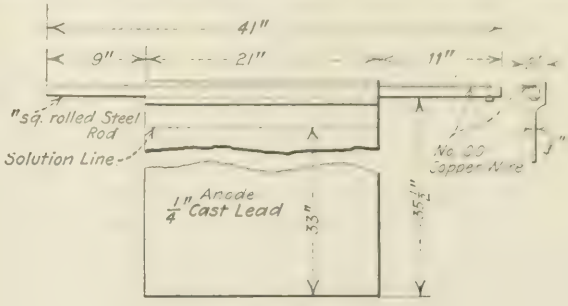


DETAILS OF BUSBAR SUPPORT

outside of the anode bus. The difference in elevation of the tanks of 3 in. makes it possible to have the top bolt holes of the lower or anode bus register with the bottom bolt holes of the top or cathode bus, the two bars and the connecting strip being bolted together with two ½ in. bolts. Two bolts secure the connecting strip to the cathode bus at the top of this strip and two bolts secure the connecting strip to the anode bus at the bottom.

THE ANODES

Anodes are made of chemical sheet lead ¼ in. thick, the area immersed being 21 in. wide x 33 in. deep. The anodes hang vertically in the tank, and are supported by 1-in. square rolled steel rods and weigh about 100 lb., complete. The supporting rod is 41 in. long and extends 9 in. beyond the edge of the anode on one side, being supported by a wood strip resting on the top of the inner wall of the tank and 11 in. on the other in order to clear the top of the outer wall of the tank and rest on the anode bus. The anode was originally supported by being cast around the rod. Electrical contact was provided by sweating the lead to the rod. This method has not proved satisfactory in operation due to the fact that zinc sulphate will creep in between the lead and the rod, causing a poor contact. This resulted in a very decided increase in electrical resistance which caused heating

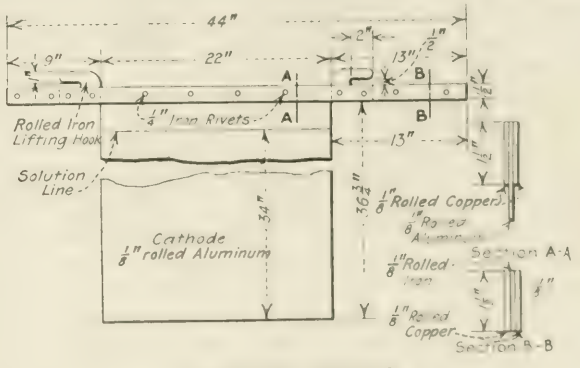


ANODE DETAILS

and further disintegration. The defect has been overcome by burning into the lead above the steel rod a length of tinned No. 00 copper wire. A hole is drilled through the iron bar where contact is made with the anode bus and the copper wire passed through this hole and riveted on the under side. This provides a copper circuit from the anode bus to the lead plate.

THE CATHODES

Cathodes are made of best rolled sheet aluminum, ⅛ in. in thickness. The immersed area is 22 in. wide x 34 in. deep. The cathode rod is made from two strips of rolled copper, ⅛ in. thick x 1½ in. wide x 44 in. long. These are riveted together with the aluminum sheet between. The rod extends 9 in. beyond the aluminum sheet on one side, being supported on the same wood strip on which the anode rod rests, and 13 in. on the other so as to clear



CATHODE DETAILS

the top of the outer wall of the tank and the anode bus and rest on the cathode bus. An iron lug is riveted between the copper strips at each edge of the aluminum sheet, forming a hook by which the cathodes are removed from the tank for stripping. The remaining space between the copper strips at each end is filled with an iron strip and the three strips are riveted together.

In each tank are nineteen anodes and eighteen cathodes which are spaced 2 in. center to center. The im-

mersed cathode area is 203.5 sq.ft. and the effective immersed anode area is 173.25 sq.ft. per tank. With a current of 5,000 amp. the density per sq.ft. of cathode area is therefore 24.5 amp. This current density was chosen as the most economical under operating conditions. The higher the current density the greater the cathode production per kw.-hr., since the resistance of the solution is practically constant for all densities. Too high a current density will, however, produce a poor cathode deposit with a resulting decrease in the current efficiency due to re-solution of the deposited zinc by the acid in the electrolyte. The amount of zinc re-dissolved is increased by rough and non-coherent deposits. The rate of flow of solution through the tanks is such that the acidity of the electrolyte leaving the last tank in the cascade is about 60 g. per liter. This acidity was also chosen as the most economical under operating conditions. The higher the acidity of the solution the greater the amount of deposited zinc dissolved, with the result that there is a decrease in the current efficiency. There are other factors, of course, to be taken into consideration in determining the most economical current density to use in relation to the amount of free acid and zinc sulphate in the effluent solution; such as the cost of cooling the solutions, the cost of power, the market price of zinc, the problem being complicated because these factors are interdependent. The voltage drop per cell will vary from about 3.7 volts in the head cell to 3.3 volts in the last cell in the cascade, the average being about 3.5 volts.

The effect of the electrolysis upon the solution is shown in Table I. It is to be noted that about 20 g. per liter of Zn remains in solution, this amount being carried through the cycle.

TABLE I. EFFECT OF ELECTROLYSIS

	Grams per Liter					
	Zn	H_2SO_4	Cd	Cu	Sb	Mn
Feed to head cell.....	59.5	0.2	0.003	0.0006	0.0010	0.415
Overflow from tail cell...	21.7	58.1	Trace	0.0003	0.0007	0.035

Manganese is deposited at the anodes as dioxide. The deposit is, however, non-coherent and all but a thin film which adheres to the anode settles to the bottom of the tanks. The tanks are cleaned of this mud about once a month; at present no use is made of this product. The solution flows directly through the tanks. It is not necessary to admit the solution near the bottom at one end of the tank with the overflow from the top at the other, or vice versa, since evolution of gas from the anode suffices to prevent stratification of the solution.

The cathodes are removed from the tanks and stripped of the deposited zinc every 48 hr., the average weight deposited per tank being about 515 lb. The smooth crystalline deposit on the cathode sheets is about $\frac{1}{8}$ in. in thickness. The cathodes are lifted from the tanks by means of a lifting frame attached to a 1-ton chain fall which runs on an overhead trolley. The lifting frame has two side-pieces made from 1½-in. angle iron and cross-braced, the toes of the angle-iron being horizontal and directed inward. V-shaped notches are cut in the toe, spaced 4 in. center to center; when the frame is lowered these notches permit the toe of the angle-iron to be slipped endwise under the lugs on the cathodes. The lifting frame removes six cathodes at one time. The cathodes are conveyed by the trolley to the aisle at the end of the section and deposited in a portable stripping frame, where the wooden side strips are removed and the deposited zinc is stripped from the aluminum sheet. The cathodes are thoroughly cleaned, dry wooden side-strips are put on each edge and are then replaced in the tank. These side-strips are made from a $\frac{3}{4}$-in. square strip of wood, 36 in. long, with an $\frac{1}{8}$-in. slot $\frac{1}{4}$-in. deep cut along one side. The wooden strips extend the full length of the cathode sheet and slip tightly over the aluminum sheet and are thus held in place. Side-strips are necessary for the convenient removal of the deposit, and also prevent the formation of irregular deposits at the edge of the sheets.

Cathodes are then melted in a coal-fired reverberatory melting furnace and cast into standard sized slabs for the market. The average analysis of the refined zinc is Zn, 99.930; Fe, 0.005; Pb, 0.038, and Cd, 0.027 per cent.

Power

The power for operating the plant is purchased from the Utah Light & Power Co. and is delivered to an outdoor transformer station at 40,000 volts, there being three independent sources of supply. The voltage is transformed to 2,300 volts for the synchronous motors and to 440 volts for miscellaneous power uses about the plant, such as operating the air compressors which supply air to the Pachucas, operating the sand and solution pumps and calcine elevators.

Direct current is generated for the tank room by two motor generator sets driven by synchronous motors, the generators being rated at 5,000 amp. at 215 volts. The switchboard installation is arranged so that either generator can be used to supply current to either section of sixty tanks. Provision is made for forced ventilation of the motor generator room by washed air.

Production

The plant was one of the first electrolytic zinc plants to be put into operation and was designed to produce fifteen tons of zinc per day, but under operating conditions that have developed the plant will require enlargement in some departments to attain this tonnage. The Wedge roaster will supply sufficient calcine for not more than nine tons of zinc and additional agitating Pachucas will also be needed in order to obtain the rated capacity. It is interesting to note that the original cells in this plant were designed to use the rotating cathodes that were developed at Bully Hill, but that with the development of the process, particularly in the purification of the solution for electrolysis, it was found to be advantageous to install new tanks and to use stationary cathodes.

Acknowledgments

Thanks are due to G. W. Lambourne, of the Judge Mining & Smelting Co., for permission to publish these notes, and to John T. Ellsmith for courteously assisting in the collection of the material at Park City.

Marking of Imported Goods

A Federal proclamation has been issued in Australia prohibiting the importation, except with the consent of the Minister of Trade and Customs, of all articles to which or to the coverings of which there is applied any marking in a language other than the language ordinarily used by the people of the country of origin, unless there is also applied to such articles or to their coverings a definite qualifying statement in the English language indicating the country in which the articles were made or produced.

The History of Mustard Gas

By Clarence J. West

THE discovery and commercial perfection of the reaction between ethylene and sulphur chloride is being aired in the controversy (*J. Soc. Chem. Ind.*, vol. 38, pp. 344R, 363R, 432R, 451R, 469R) which has grown out of an attempt on the part of Dr. H. Levinstein (*J. Soc. Chem. Ind.*, vol. 38, p. 248T) to defend the German Chemical Service against the criticism of Sir William Pope (*J. Chem. Soc.*, vol. 115, p. 397; 1919) that the service was inefficient because of the method employed for the early manufacture of mustard gas. There is no attempt to question the loyalty of Dr. Levinstein or of the men associated with him, for their services in the great war place that beyond doubt. The questions at issue appear to be to whom credit should be given for the discovery of the reaction and how much credit is due to each party for its commercial development. There also seems to be a fear on the part of our British allies that America claims the reaction as her own, from a statement in Dorsey's article (*J. Ind. Eng. Chem.*, vol. 11, p. 281; 1919). It has been clearly recognized all through the war that we were indebted to the British for the information, not only regarding this but many other processes and developments. If full credit has not been given it is not because of any desire on our part to claim things not our own. A further question, which must be settled in the laboratory, involves the chemistry of mustard gas, and in particular its reaction with sulphur chloride.

Chlorhydrin Process

The early method of preparation of mustard gas, used both by the Allies and by the Germans, was based upon the reaction as published by Victor Meyer in 1886 (*Ber.*, vol. 19, p. 3,260) and further studied by Clarke (*J. Chem. Soc.*, vol. 101, p. 1,583; 1912). This consisted in the formation of dihydroxyethyl sulphide by the interaction of sodium sulphide and ethylene chlorhydrin:

$$2ClCH_2CH_2OH + Na_2S = (HOCH_2CH_2)_2S + 2NaCl,$$

and the subsequent reaction with HCl or thionyl chloride:

$$(HOCH_2CH_2)_2S + 2HCl = (ClCH_2CH_2)_2S + 2H_2O.$$

This method was adopted because analyses of German duds showed fairly conclusively that Germany was manufacturing its mustard gas in this way. English and American chemists, therefore, spent several months in improving and adapting Meyer's method to commercial operation. (See, for example, Gomberg, *J. Am. Chem. Soc.*, vol. 41, p. 1,414; 1919.) First of all, a method had to be developed for the large-scale production of ethylene. This was successfully solved by the British through the use of alcohol vapor and heated phosphoric acid (Newth, *J. Chem. Soc.*, vol. 79, p. 915; 1901; Pope, *J. Soc. Chem. Ind.*, vol. 38, p. 345R; 1919). The Americans found that passing a mixture of alcohol and water vapors over kaolin heated to 500-600 deg. C. gave a satisfactory yield of a very pure product (Dorsey, (*J. Ind. Eng. Chem.*, vol. 11, p. 288; 1919). The second step, the production of ethylene chlorhydrin by the reaction of ethylene, chlorine and water, was less successful. Confidential information from British sources show that Irvine developed a catalyzer for the reaction that was fairly satisfactory. Gomberg was able to work out a satisfactory laboratory method and condition for purification which offered commercial possibilities, but at that time the need no longer existed. The other steps offered little difficulty, but everyone is convinced that, as Dorsey states, "the process used by Meyer, namely, the chlorhydrin procedure, proved to be unsatisfactory for huge-scale production." Fortunately, through the efforts of Pope and Levinstein, the method was not needed.

Ethylene-Sulphur Chloride Reaction

The early history of the reaction between the sulphur chlorides and ethylene (the reaction which is the subject of the controversy) is very unsatisfactory. It appears that Despretz (*Ann. chem. phys.*, vol. 22, p. 428) observed the formation of a disagreeably smelling fluid by the reaction of ethylene upon sulphur chloride. Niemann (*Ann.*, vol. 113, p. 288; 1860) obtained a product which he believed to be the disulphide, $(C_2H_4)_2S_2Cl_2$, by the action of ethylene upon a mixture of the two sulphur chlorides ("brown" sulphur chloride), of which he says:

"The characteristic property of this oil is also a very dangerous one. It consists in the fact that the minutest trace which may accidentally come in contact with any portion of the skin, though at first causing no pain, produces in the course of a few hours a reddening and on the following day a severe blister which suppurates for a long time and is very difficult to heal."

The same year Guthrie (*Quart. J. Chem. Soc.*, vol. 12, p. 117; 1860) studied the reaction of ethylene upon sulphur dichloride, and the following year the reaction with sulphur monochloride. Since he allowed the ethylene to remain in contact with the chloride for 20 hr. at 100 deg., it is very unlikely that he had any mustard gas. This is supported by the fact that the product was non-toxic and produced only a slight soreness when placed beneath the tongue. From the experiments carried out by the Chemical Welfare Service, it is very doubtful whether Green is correct in his statement that "mustard gas can be produced of satisfactory purity and in good yield by reacting ethylene with sulphur monochloride at a temperature which is never below 100 deg. throughout the whole reaction." This is the experience of Pope, who reports that at a temperature above 65 deg. practically no mustard gas is formed. On the other hand, Green is undoubtedly right in his contention that pure mustard gas is not materially attacked by sulphur chloride. These facts are probably explained by the formation of an intermediate compound of ethylene and sulphur chloride as observed by Conant (See *J. Am. Chem. Soc.*, vol. 42, p. 585; 1920).

This reaction was next studied by Spring (*Bull.*, vol. 48, p. 629), who ascribed to the product the formula

$$ClCH_2CH_2S\text{-}SCH_2CH_2Cl.$$

Failure of the Sulphur Dichloride Process

The possibility of preparing mustard gas by the reaction of ethylene and sulphur dichloride was suggested in America in 1917. Several laboratories (unpublished reports, Bureau of Mines) tried the reaction, but obtained a compound containing three chlorine atoms. This is perfectly clear in view of the studies of the behavior of pure mustard gas or its solutions with sulphur dichloride; a chlorinated mustard gas results, which has about the same boiling point as pure mustard gas, but which is practically lacking in vesicant properties. The reaction was therefore dropped for the time and all energies were concentrated on the chlorhydrin method.

In January, 1918, a cablegram was received by the

American Gas Service to the effect that Pope had succeeded in preparing mustard gas from ethylene and sulphur dichloride. In spite of very careful trials the method could not be duplicated by the American University. It was natural that attention should be turned to the monochloride, and the day previous to the receipt of a cable from England to the effect that Pope had successfully carried out the reaction, the experiment was started by Conant. There is thus no question as to Pope's claim to the reaction. Green has made much of the fact that the reaction is not entirely novel, as Pope claims, and in this he is probably justified. The reaction is recorded in the literature and in Beilstein. Credit is due him, however, not only for calling attention to this reaction but in showing that, on a laboratory scale, the reaction was very simple and gave a mustard gas in good yield and of sufficient purity so that it appeared perfectly feasible to proceed with a commercial development. All the world now realizes how much this meant to gas warfare.

Laboratory Method Modified in Factory

Every one who has attempted to place a laboratory reaction into commercial production will sympathize with the attitude that Green takes [*J. Soc. Chem. Ind.*, vol. 38, p. 363R] regarding the amount of research necessary. It should be a well-recognized fact that no laboratory method is directly applicable to factory conditions, and further, that in a large number of cases the conditions of operation may entirely change as the result of experience gained in the factory. It is not surprising, therefore, that Levinstein, Ltd., having the fundamental idea as developed by Pope, should be able so to modify the reaction conditions that a superior working method and product should result. Had Pope followed the method into factory production, which he did not do, he probably would have made the same observations.

The reaction was also studied on a small and large scale by the American Chemical Warfare Service, and while it was able to work out a satisfactory process, it was very glad to adopt the Levinstein "reactor" as soon as it was demonstrated; and in all reports, the American chemist was very careful to refer to it as Levinstein's process.

Williams [*J. Soc. Chem. Ind.*, vol. 38, p. 451R] calls attention to the fact that the H. M. Factory, Avonmouth, was also concerned in the development of Pope's reaction on a commercial scale, but it apparently did not accomplish the elimination of sulphur deposition, though it was recognized as an evil to be overcome.

According to Pope, England seems to have suffered from a lack of co-ordination of "scientific advisers" and technical men. Apparently all the scientific men were not consulted in the matter of the best method to be employed, although we believe that such men as Irvine were intimately connected with the early history of mustard gas. It must not be supposed, however, that their scientific advisers did not make use of their opportunities. Mention of mustard gas, of the new synthesis of diphenylchlorarsine and the discovery of D.M. is sufficient to show how very valuable their services were to gas warfare in general.

America was fortunate in that all of her chemists worked together and that finally a very complete organization was built up in the Chemical Warfare Service through the efforts of Major General Sibert. The success of this organization is evidenced by the gas program planned for the year 1918-1919.

May we not then give Sir William Pope the credit for having called attention to the one satisfactory method of preparing mustard gas, and for the laboratory demonstration of this reaction, and to the technical chemists of England and America, and especially to Levinstein, Ltd., for having surmounted the many factory difficulties in putting the reaction into the plant, and finally to the men of the Chemical Warfare Service of all countries for their faithfulness under conditions not always agreeable in its actual manufacture?

Current Activities of the Bureau of Mines Stations

THE investigations conducted at the various stations of the Bureau of Mines are of interest in that they reflect the problems that are confronting the mineral industries and the trend of metallurgical developments in this country.

Berkeley (Cal.) Station

The Berkeley Station is investigating the reaction between silver chloride and water vapor and between metallic silver and hydrochloric acid. This is in connection with the volatilization of the chlorides of silver, copper, lead and zinc as a means of recovering these metals from ores that are not amenable to usual metallurgical methods. This latter problem is being studied in detail by the metallurgists at the Salt Lake City Station. The Berkeley Station is also working in co-operation with the Northwest Magnesite Co. on the problem of producing caustic magnesite from deposits which occur in the Western States. It has first been necessary to standardize and improve technical methods of analysis and to perfect an exact method for the determination of calcium. Work is also being done to determine the effect of the time-temperature-size-of-particle factors in the calcination of magnesite and in determining the tensile strength of magnesian mortars.

Bartlesville (Okla.) Station

The work at the Bartlesville Station is primarily in connection with the problems related to the production and refining of petroleum and natural gas. The losses due to evaporation in the storage of oils are being studied in the Oklahoma, Texas and California fields. The reduction of the loss is of importance in view of the increasing demand for gasoline. The losses which occur in the fire distilling of mineral seal oils are also being investigated. The heating value of gases that have been treated for the recovery of gasoline is being compared with that of untreated gas. Field work covers investigation in various oil and gas fields.

Columbus (Ohio) Station

Ceramic investigations are being conducted at the Columbus Station. The comparative qualities of bond clays in the production of graphite crucibles used in the melting of brass and steel have been determined. Further investigations are to be undertaken to determine the comparative value of American and imported graphite. Tests are conducted to determine the value of clays for different uses such as for pottery, building and fire brick.

Fairbanks (Alaska) Station

The Fairbanks Station deals with the minerals and ores from the Alaska district. Black sands in different localities are being tested for gold and platinum; where these metals are found in paying quantities, concentration methods are worked out. Black sands from Fairbanks Creek and from Goldstream are now being investigated. Methods for the separation of copper from pyrrhotite in ores from the Kennecott Copper Corp. at Latouche are being investigated. Custom assaying is also carried on at this station.

Golden (Col.) Station

At the Golden Station radium research is conducted. The spectra of krypton and xenon have been the subject of investigations by Dr. Moore and Dr. Lind of the station in co-operation with Prof. Nysander of Denver University. Dr. Marden of the University of Missouri has completed a monograph on the analytical methods of zirconium. Key West copper-nickel-platinum ore from Pioche, Nev., has been examined, and preliminary investigations indicate that a separation of the copper and nickel can be made by differential flotation and that 85 per cent of the platinum can be recovered. A co-operative agreement among the Primos Chemical Co., the Bureau of Mines and the Colorado School of Mines has been entered upon to conduct research work on molybdenum steels. The factors which influence the phosphorescence of zinc sulphide are being investigated by C. W. Davis. The production of a luminous paint from this material will help conserve the limited supply of radium. J. E. Conley is experimenting with a descloizite from Goodsprings, Nev. The removal of the vanadium from this low-grade ore carrying a highly calcareous gangue is being attempted by passing dry chlorine over the reduced ore at low temperature. About 85 per cent of the vanadium was volatilized without the calcite being appreciably attacked. Mr. Conley is also preparing a chapter on the analytical methods of vanadium.

Minneapolis (Minn.) Station

The Minneapolis Station is erecting an experimental iron blast furnace, the blowing in of which has been delayed by the unusually early and severe winter weather. The Fuel Division has been working on the economical use of fuels common to the Northwest in house-heating units. The work has demonstrated that economy may be effected by proper burning of these fuels and the public has evidenced an appreciation of this work. C. E. Plummer is investigating the standardized methods of determining phosphorus in iron ores and the separation of manganese and magnesium in iron blast furnace slags.

Pittsburgh (Pa.) Station

The work of the Pittsburgh Station in the physical testing of explosives and in the examination of explosives to be put on the permissible list is being carried on as usual. Messrs. Howell, Munroe, Rice and Hall have been appointed on a committee to consider the rules and regulations governing the testing and placing of explosives on the permissible list. An investigation is being conducted in co-operation with the New York and New Jersey State Bridge and Tunnel Commission to determine the amount and composition of exhaust gases in motor vehicles to obtain data for the ventilation of the proposed tunnels under the Hudson River. A new furnace and apparatus has been built for the study of the forms of coal sulphur carbonized at temperature of 500 deg. C. and over. Additional data are being gathered in regard to scrap loss in aluminum foundry practice and the available statistics are being correlated. Metallographic and chemical work in connection with typical defects in aluminum castings is being conducted. Methods for the analysis of aluminum and its alloys are being investigated. The Fuel Section is conducting boiler tests for the United States Emergency Fleet Corp. in determining the efficiency of oil-burning equipment.

Salt Lake City (Utah) Station

The work on chloride volatilization is being continued at the Salt Lake City Station. Recent test runs on ore from Yellow Pine Mining Co. from the Goodsprings district in Nevada showed an extraction of 83 per cent of the lead and 88 per cent of the silver. In these runs salt was used as a chloridizing agent and powdered calcium chloride was introduced into the discharge end as a volatilizing reagent. Silver-lead residue from zinc retorts and oxidized copper ores are also being investigated to determine the adaptability of this method for recovery of the metals. Ore of the Tintic Standard mine was treated for the extraction of silver and lead in concentrated acid brine solution.

Seattle (Wash.) Station

At the Seattle Station attention is being given the problem of the utilization of Washington coal. Fuel oil shortage has necessitated the use of the available coals from the district. Investigations cover the field of mining, washing, briquetting and the utilization of powdered coal. The co-operation work with the Idaho School of Mines at Moscow covers differential flotation experiments on lead-zinc ores and cyanidation tests of gold-silver ores from Idaho.

Tucson (Ariz.) Station

At the Tucson Station co-operative work is being carried on with the Miami Copper Co. Equipment is being installed to investigate the leaching of low-grade copper ores by sulphur dioxide. Equipment at the Miami plant has been recently overhauled, a counter-current decantation system has been added for the clarification of copper sulphate solutions, also a Cone settlement apparatus for the recovery of precipitated copper. The production of sponge iron for the precipitation of the copper from solutions is being investigated. Dr. C. M. Bouton, of the Berkeley Station, has been detailed on special chemical investigations connected with SO_2 leaching problems.

Urbana (Ill.) Station

The Urbana Station is investigating the coals of the Midwest field. W. W. Odell has submitted plans to the Chicago gas companies whereby improvement in operating efficiencies may be obtained.

San Francisco (Cal.) Station

The San Francisco Field Office is studying the problem of reducing the viscosity of heavy asphalt-base crude oil. The work is being conducted by C. P. Bowie and M. J. Gavin. Mr. Gavin is also investigating the problem of oil-shale development. A. R. Elliott is investigating the evaporation losses and changes in temperature of oil in storage.

A Test on Sulphur Content of Clean, Cold Producer Gas

By Carl F. Kaufmann

THE field of uses for clean, cold producer gas has broadened to such an extent that this gas is now bidding for the place long held by hot, raw gas in the making of steel by the open-hearth process. In this connection the presence of sulphur in the gas must be considered, as naturally a high sulphur content will have a deleterious effect upon the steel. The sulphur exists in the raw producer gas in three forms: hydrogen sulphide, carbon bisulphide and sulphur dioxide, but principally in the forms of hydrogen sulphide and carbon bisulphide in the proportion of about one of the former to two of the latter. The ratio varies with the character of the coal used.

The writer directed an extensive series of analyses conducted to ascertain the quantity of sulphur contained in the coal, the amount going down with the ash, the quantity carried over by the raw gas, the quantity absorbed by water in both the primary and secondary condensers, the quantity carried off in the tar, and the quantity that is finally present in the clean, cold producer gas.

At the start of the test the bunkers were stocked with a 24-hr. supply of coal, and during the test, approximate analyses were made from samples taken from the chutes to the producer, at intervals of two hours so as to insure a fair average representation.

The approximate analysis of the coal is given as follows:

	Per Cent		Per Cent
Moisture	1.37	Ash	9.59
Volatile and organic	36.23	Sulphur	1.81
Fixed carbon	51.00		
B.t.u. per lb., (calorimeter)			13,709

The quantity of coal burned in the producer was 58,900 lb. As the sulphur content of the coal was 1.81 per cent, the total sulphur present was therefore 1,066.09 lb. There was produced from burning the above quantity of coal 5,706.5 lb. of ash containing 92.5 per cent mineral and 7.5 per cent combustible matter. The sulphur present in the ash analyzed 0.16 per cent by weight, equaling 9.13 lb. Deducting this quantity from that contained in the coal leaves a total of 1,056.96 lb. carried off from the producer in 3,540,000 cu.ft. of raw gas to the primary condenser.

The volume of water supplied to the primary condenser in 24 hr. as indicated by a Bailey flow meter was 314,000 gal., to the secondary condenser 156,000 gal.

Analysis of the condenser water before using is given as follows:

	Parts per 100,000		Parts per 100,000
Silica	2.64	Calcium sulphate	32.78
Iron dioxide	0.14	Calcium chloride	38.03
Aluminum oxide	0.11	Magnesium chloride	23.30
Calcium carbonate	26.50	Sodium chloride	162.84

Analysis of the primary condenser water, determination made every 2 hr., averaged 14.4857 grains per gal., or for the total volume of water, 649.79 lb. The secondary condenser water showed an absorption of 14.3689 grains per gal.; for the total volume of water, 320.22 lb.

The quantity of tar distilled and separated by the extractors was 366.75 gal. delivered to the tar decanter. Taking the weight of tar as 8.336 lb. per gal., it will follow that the total weight of the tar equals 3,058.228 lb. The sulphur present in the tar analyzed 0.253 per cent by weight, or a total quantity of 8.737 lb.

The ultimate analysis of the gas showed a sulphur content of 0.1451 grain per cu.ft., or a total of 73.78 lb. contained in the 3,540,000 cu.ft. of gas produced.

Ultimate analysis of gas is given as:

	Per Cent		Per Cent
Carbon dioxide	5.00	Hydrogen sulphide	0.02
Carbon monoxide	23.20	Hydrogen	11.80
Oxygen	0.60	Nitrogen	54.18
Methane	5.20		

RECAPITULATION

Duration of test, hr.	24
Coal consumed, lb.	58,900
Ash produced, lb.	5,706.5
Tar distilled, lb.	3,058.2
Gas produced, cu.ft.	3,540,000
Water consumed, primary condenser, gal.	314,000
Water consumed, secondary condenser, gal.	156,000
Temperature water entering primary condenser, deg. F.	58
Temperature water leaving condenser, deg. F.	125
Temperature gas entering condenser, deg. F.	1,000
Temperature gas leaving condenser, deg. F.	120
Temperature water entering secondary condenser, deg. F.	58
Temperature water leaving secondary condenser, deg. F.	72
Temperature gas entering condenser, deg. F.	124
Temperature gas leaving condenser, deg. F.	68
Sulphur content in ash, lb.	9.13
Sulphur content in water primary condenser, lb.	649.79
Sulphur content in water secondary, lb.	320.22
Sulphur content in tar, lb.	8.74
Sulphur content in gas (ultimate analysis), lb.	73.78
Sulphur content unaccounted for, lb.	4.43
Sulphur content in coal, lb.	1,066.09
Sulphur content in gas, grains per 100 cu.ft.	14.31

Crucible Steel Co. of America.

Aluminum in Norway

ACCORDING to a report by R. B. Ladoo of the Bureau of Mines (Monthly Reports of Investigations, December, 1919), Norway has not previously been a producer of aluminum, having been wholly dependent upon imports, but during the war the Hoyangfaldene Co. was formed to undertake domestic production. Jetland Falls, from which the Hoyanger plant obtains its power, furnishes an available 80,000 hp., of which 30,000 hp. has been utilized at a cost of 6,708,207 kroner ($1,811,215.90 at the normal exchange rate). It is estimated that the total development cost for the whole plant installed will be 300 to 350 kroner ($80 to $95) per hp. The whole enterprise includes works which will produce 7,000 tons of metallic aluminum, 5,000 tons of electrodes and 12,000 tons of carbide.

No sources of bauxite are known in Norway, but the company is affiliated with the Société des Alumines & Bauxite de Provence, of France, which owns adequate sources of bauxite.

In the meantime the Hoyangfaldene Co. has been manufacturing electrodes, carbide and iron and has been experimenting on a large scale with domestic raw materials to discover a local source of aluminum ore, and it is reported that results are encouraging.

Alumina From Labradorite

In this connection it is of interest to note that the development of a process of extracting alumina from labradorite has recently been reported from Norway. The process involves the solution of labradorite in dilute nitric acid made locally, leaving the impurities as a residue; evaporation and heating to a point at which the aluminum nitrate alone is decomposed, and dissolving the calcium and sodium nitrates in water, leaving pure aluminum oxide. Labradorite, as ordinarily found in this country, is not sufficiently soluble in nitric acid to make this process seem feasible on a commercial basis; but it is possible that the Norwegian material is not a true labradorite and is much more soluble. Pure labradorite contains about 30 per cent alumina or 16 per cent aluminum.

Aluminum Rolling-Mill Practice—II Melting Furnaces—Ingot Pouring

Continuous Versus Intermittent Melting, Prior to Casting Rolling-Mill Ingots, Is Discussed by the Authors in Their Second Installment—Correct Melting and Pouring Practice for a Minimum of Drossing Is Also Indicated*

BY ROBERT J. ANDERSON AND MARSHALL B. ANDERSON

FOR casting into rolling ingots, aluminum is melted in gas- or oil-fired (and occasionally coal-fired) furnaces of the open-flame reverberatory type, and in electric furnaces. Ordinarily, open-flame gas-fired furnaces are preferred; the firing is accomplished by the combustion of the fuel ejected from burners and with the aid of air. A typical gas-fired furnace is one of 5,000-lb. capacity (2,300-kg.), and such a furnace will consume about 1,000 cu.ft. of natural gas per hr. (28 cu.m.) under the conditions of fast melting practice. Gas- and oil-fired furnaces for melting aluminum for casting into rolling ingots are represented by a number of common types, for example the Rockwell, and no lengthy description will be given now. The usual furnace is built with a refractory hearth or bottom of firebrick and with inside walls and roof of the same material. The outside walls are made of common brick; the whole furnace is bound firmly together with channels or I-beams and stay rods. There may be two or more burners to a furnace; one type has two burners, one at the front situated so that the flame is about 12 in. (30 cm.) above the bath, and the other at the rear but about 30 in. (75 cm.) above the bath. Melting furnaces using gas or oil for fuel may be built in pairs, i.e., the side of one furnace abuts the side of another. Charging and cleaning are accomplished through a door at one side, and the metal is tapped through a tap hole at the front.

Coal-fired furnaces have been used for melting aluminum, but there are certain definite disadvantages which arise with the use of these furnaces. They are built with a firebox at one end; the flame sweeps over a bridge wall and across the metal, and finally out through a stack. One difficulty in the use of coal lies in the lack of anything like accurate control of temperature. From the rolling mill standpoint, another disadvantage lies in the fact that metal melted in coal-fired furnaces is usually more dirty and discolored than metal which has been melted in gas-fired or oil-fired furnaces. This statement is based upon inspection of ingots, slabs and sheets.

Use of Electric Furnaces

Electric furnaces have lately received some attention in the United States for aluminum melting. In particular, the Baily resistor furnace[6] has been used for this purpose. Offhand, electric furnaces might appear to be entirely unsuited to aluminum melting because of the fact that high temperatures are usually associated with these furnaces. Arc furnaces do not appear to be desirable appliances for aluminum melting, but resistor-type furnaces apparently have some advantages. Even though aluminum melts at a rather low temperature, it may be considerably superheated in a neutral atmosphere without ill effects or large volatilization losses because the boiling point[7] is quite high: viz., 1,800 deg. C.

It is assumed by some that reducing atmospheres follow from the use of electric-arc furnaces or electric-resistor furnaces using a carbon-base resistor. A reducing atmosphere will not be obtained in these furnaces unless the furnace is tightly luted so as to prevent ingress of air, and the average furnace will not be operated in this way. With resistor-type furnaces, better control of temperature is possible than with either gas-, oil- or coal-fired furnaces. A neutral or reducing atmosphere is rather difficult to maintain in gas- or oil-fired furnaces under the conditions of melting.

With regard to furnace atmospheres, there is this to be said: Under the usual conditions involved in charging continuous heats the doors are open for such a considerable portion of the time that no particular atmosphere could be maintained very long.

Melting for Minimum Dross

A usual method for melting aluminum prior to ingot casting, in reverberating furnaces, calls for charging into a hot furnace, say, 5,000 lb. (2,300 kg.) of cold metal, i.e., pigs alone or plus scrap. When the charge is melted, ingots are poured until the furnace is empty. This is a rather uneconomical procedure in the case of 24-hr. practice. Aluminum is readily oxidized in the presence of air and rapidly with increasing temperatures. Under the above conditions, a large surface area of metal is exposed to both air and a free flame; this normally results in high dross losses. If reducing conditions could be positively and completely under control at all times, then the case would be altered.

Dross, in aluminum melting practice, is understood to consist of aluminum oxide (Al_2O_3 or some other oxide) plus metallic aluminum mechanically entangled. Dross losses resulting from poor melting methods have, at times, amounted to as much as 3 per cent of the total metal charged, but this, as shown later, is an excessively high figure for good practice.

In order to melt aluminum for ingot casting, a method more to be preferred than the one above is as follows: To a hot furnace, charge about 500 lb. (230 kg.) of pig metal, and when this has been melted continue adding more pigs from time to time until the whole charge has been put in. After each addition the cold pigs should be put down below the surface of the

*For Part I see CHEM. & MET. ENG., vol. 22, No. 11, p. 489, March 17, 1920.

[6]Dwight W. Miller, "The Remelting of Aluminum Pig in the Electric Furnace," CHEM. & MET. ENG., vol. 19, 1918, pp. 251-254.

[7]Smithsonian Physical Tables, 1918, p. 218.

bath, and sufficient time should be allowed for them to melt before adding more cold metal. There will be no difficulty in keeping the cold metal under the surface, because the density of liquid aluminum is less than that of solid aluminum. In this way the smallest possible surface is exposed to the action of the flames, and oxidation is kept lower than otherwise.

If the endeavor is made to keep the temperature of the bath low in order to avoid gas absorption, excessive oxidation, and the formation of aluminum nitride, then too much cold metal should not be added at one time, or the whole bath may freeze. Normally, however, there is not an accurate control of the bath temperature, and usually the bath will be sufficiently hot so that several hundred pounds of cold pigs can be charged at intervals of one hour.

Aluminum melting may be either intermittent or continuous; in the former a furnace is charged, and the metal is melted in the manner just described; the entire melt is then poured into molds, the furnace is recharged, and the whole operation is repeated. In continuous melting, a furnace is started as in intermittent melting, and additional metal is added from time to time (usually every hour or so) in order to keep pace with the rate of ingot pouring. In this method, a furnace is always practically full of metal, but it presupposes 24-hr. operation unless it is desired to hold a bath of hot metal over night. This latter is hardly advisable, since furnace breakouts might occur.

Continuous Melting

A continuous heat may run for about one week, being started on Monday and continuing until the end of the week, when the furnace is emptied and cleaned. For an example, it may be assumed that a 5,000-lb. heat is in the furnace in the liquid condition and that pouring of ingots has commenced. It is the duty of the furnace fireman to keep the furnace full of metal and at a sufficiently high temperature at all times so that ingot pouring will not be delayed. In order to do this, he should keep account of the number of ingots poured during a given time, say 1 hr.; at the end of that time sufficient pig or scrap, or both, should be added to replace the metal already tapped from the furnace. Thus, if there had been poured ten ingots of the 4 x 12 x 17-in. size (10 x 30 x 43-cm.), weighing approximately 76 lb. (35 kg.) each, the fireman should add twenty-three pigs of the 33-lb. (15-kg.) size, or an equivalent weight of pig plus scrap. If the additions are not made at regular intervals, too much cold metal may be charged at one time and the bath will be unduly chilled.

For practical purposes, in the case of a 5,000-lb. (2,300-kg.) furnace, the danger limit is 3,500 lb. (1,600 kg.) of metal in the furnace. If the bath is allowed to fall below this amount, the fireman will not be able to keep the furnace at a high enough temperature so that ingots may be poured continuously. This trouble soon culminates and stops production. When less than about 3,500 lb. of hot metal at the correct temperature is in the furnace, not more than twenty-five cold pigs of the 33-lb. (15-kg.) size can be charged at one time, since otherwise the bath will be unduly chilled; it will require at least 60 min. for 800 lb. (350 kg.) of cold pigs to go into solution, and in that time about 800 lb. of aluminum will have been poured into ingots. It will again not be feasible to charge more cold metal for another hour, and in the meantime more ingots will have been poured. Hence the difficulty becomes cumulative, and if the cold metal is not charged at regular intervals to keep pace with the rate of pouring, production on the furnace must be stopped in order to allow time for the bath to regain the correct pouring temperature. In short, the rate of charging cold metal, in continuous melting, should correspond closely with the rate of pouring, with the object of maintaining the temperature of the bath reasonably constant.

The relative merits of continuous and intermittent melting may be summed up as follows:

(*a*) In small plants or where the production is irregular, or elsewhere if the melting capacity is greater than the rolling capacity, intermittent melts will be employed.

(*b*) Intermittent melts give more uniform ingots, as to composition, when mixed pig and scrap, or all scrap charges, are run.

(*c*) Intermittent melts may possibly have some advantages in that they allow better separation of dross. The evidence is not entirely clear on this point, but more uniformity in the subsequent sheets is usually found.

(*d*) On the other hand, continuous melts are cheaper from the standpoint of fuel consumed and labor employed.

(*e*) Continuous melts give greater production for a given melting capacity.

Intermittent Melting

The above remarks refer to either reverberatory-type or electric-furnace melting. In order to avoid the less efficient night work, a small plant will cast ingots only by day. For large plants where the production is irregular, it will not be advisable to run the melting department at capacity when the rolling and fabricating departments are not at capacity also. Again, if the melting capacity is out of proportion to the rolling capacity, e.g., larger, then it is advisable to melt intermittently, because in this way the melting can be so carried out as to keep pace with or be a little ahead of the rolling.

Greater uniformity of ingot composition can be obtained by intermittent melting, for the reason that it is possible to obtain separate lots of metal of practically the same composition. It is difficult to keep scrap assorted according to lot, and the pig composition itself may be somewhat variable. Lots of scrap from slab shearing can readily be kept separated, but it is more difficult to segregate shearings on finished sheet and pack trimming, and practically impossible to keep any accurate account of small fabricating scrap by lots.

With intermittent melts, more men must be employed at short intervals for charging; with continuous melts, one man could charge two furnaces and be kept busy most of the time. Melting furnaces are charged by hand, and the labor is not severe.

Time required for melting a cold charge of aluminum varies with type of furnace, character of the charge, and with available working temperature of the furnace. Electric furnaces will melt aluminum more rapidly than will open-flame furnaces, for the self-evident reason that higher temperatures can be obtained. Medium scrap in the loose or baled condition will melt more rapidly than massive pig metal.

In order to give a specific idea of the time required to melt aluminum charges under mill conditions, there may be considered a gas-fired furnace of 5,000-lb. (2,300-kg.) capacity. Starting with a cold furnace, it

requires 6 to 10 hr. to heat the interior to 900 deg. C.: if pig metal be then charged as fast as it will melt, it will require about 4 or 5 hr. more to melt 5,000 lb. of aluminum and superheat it sufficiently for casting.

It also takes time to remove as much of the already formed dross as possible before starting to pour ingots. Consider the case of an open-flame reverberatory furnace of 5,000 lb. capacity, it being also assumed for purposes of illustration that the furnace is run continuously during the day, that no ingots are poured at night, and that a capacity heat is put in the furnace over night. In the morning, the day fireman should clean the bath before any pouring is started. Cleaning may be accomplished by the use of about 5 lb. of zinc chloride, $ZnCl_2$, to a 5,000-lb. heat. This reagent should be placed in a long-handled ladle and run back and forth through the bath from one side of the furnace to the other, below the surface. The bath should then be stirred vigorously with a long-handled pointed prong in order to insure thorough mixing of the zinc chloride. After allowing the melt to stand for about 10 min., the accumulated dross on the surface may be removed by a skimmer. While the value of zinc chloride is still a matter of contention among aluminum melters, it appears to be of some advantage for cleaning aluminum heats before ingot pouring.

Removing Molten Metal

One feature of aluminum-melting furnace design which is of interest lies in the provision for removing the metal from the furnace to the pouring crucible. In general, there are two ways in which this may be accomplished; first, by tapping the metal through a tap hole and runner, and, second, by ladling the metal out through a door. Of the two methods, the former is to be preferred. In tapping, the tap hole has been previously plugged with a 50:50 dough-asbestos ball on the end of an iron-handled cone; to tap, the cone is pulled out of the hole, and the metal flows down the runner. The hole is then replugged with a new ball. Difficulties occasionally arise by the metal freezing up around the tap hole; this is more often due to poor design of the tap hole than to the method itself.

Ladling is very bad practice, in the opinion of the writers. The ladle is usually hung on a swing at one of the furnace doors, and the metal is ladled out until sufficient has been placed in the pouring crucible. In this way there is more opportunity for the metal to cool than when tapping; further, it is much slower. In addition, there is more opportunity for dross to become entangled with the pour because several ladlesful are necessary to fill the pot; each ladle of metal will be more or less covered with dross. It is possible that there may be some advantages in using large tilting crucible furnaces for aluminum melting; such furnaces would empty more easily than either tapping or ladling, and there would be less opportunity for overheated melts.

Temperature Control

Pyrometric control of aluminum-melting furnaces has apparently not been applied to any considerable extent, but definite advantages would follow from the control of melting temperatures. There have been certain difficulties in the way of pyrometric control of aluminum melting, but these are not insuperable. In open-flame furnaces, iron-protection tubes break down rather rapidly under the flame action, while alundum and silica tubes are too fragile for heavy duty. Irrespective of what kind of thermocouples are used for taking temperatures, there is the liability that they will be damaged during charging if they are kept in the furnace at all times. Thermocouples have been permanently installed, on some furnaces, in the roof or side walls, or both; the recorded readings do not furnish the temperature of the bath of course, but may be more or less useful. These readings may be supplemented by taking the actual bath temperature at regular intervals by means of a portable pyrometer. At the present time, it appears that the most reliable and simplest method of pyrometric control of aluminum melts is to take temperature readings every 30 min. or so with a portable pyrometer. Aluminum is cast into rolling ingots at 700 to 760 deg. C., the temperature depending upon the size of the ingots.

Dross

As has already been noted, one of the principal sources of metal loss in aluminum melting is that resulting from oxidation according to

$$2Al + 3O = Al_2O_3$$

or possibly

$$3Al + 4O = Al_3O_4$$

Prevention of oxidation is one of the main difficulties with which aluminum melters have to deal. Whether the oxidation is due to an oxidizing flame, or to air entering the furnace when the doors are opened or through cracks, does not alter the final result. The specific gravity of aluminum oxide, Al_2O_3, is 3.73 to 3.99, that of the amorphous oxide being 3.85; it melts at 2,020 deg. C. Since aluminum oxide has a greater density than liquid aluminum, the tendency for the oxide formed would be to sink to the bottom of a bath and collect there; the viscosity of the metal may prevent such a separation in part, and surface tension can help in maintaining an oxide scum on the bath surface. Moreover, the possibility of aluminum oxide being soluble in aluminum should not be overlooked. Consideration of these factors, however, is liable to lead to speculation, and the fact is that the necessary information is lacking as to what actually takes place during dross formation in melting practice.

For the purpose of the present article, it is sufficient to know that the most serious losses in aluminum melting result from oxidation, and that care should be taken to guard against excessive dross losses. That excessive dross losses may be prevented by fairly simple precautions will be shown. In practice, it is found that whenever a furnace is emptied a considerable amount of dross has collected on the bottom; cleaning the furnace practically amounts to scraping out this accumulation of dross. During melting, aluminum oxide is probably being formed continuously, and it appears that part of this oxide finds its way to the bottom of the bath, given sufficient time. In some instances, the dross collected at the bottom of the bath has been removed by scraping it out through the bath in order to prevent it from being carried into the pouring crucible on tapping; much aluminum is also removed in this way, and it is doubtless better to remove dross by cleaning the bath with zinc chloride before pouring and then clean out the furnace after all the aluminum has been tapped and the furnace drained of metal. During the pouring of ingots, the bath also should be scraped off every 2 hr. or so with a skimmer to remove the surface dross. The use of zinc chloride for cleaning

melts has already been described. On a 5,000-lb. (2,300-kg.) intermittent heat, about 50 to 100 lb. (23 to 46 kg.) of dross will be removed from the emptied furnace, equivalent to 1 to 2 per cent by weight, in addition to the amount which is removed from the surface of the bath during pouring and that taken off the ladles.

This dross is not entirely aluminum oxide, but contains perhaps from 30 to 60 per cent metallic aluminum mechanically entangled with the oxide; the amount of metallics in dross depends upon the care with which the bath is skimmed. Dross also contains iron, silica, and other impurities. On continuous heats, the dross removed at the end of a week's run will be much larger in quantity, usually from 300 to 500 lb. (135 to 230 kg.), and the daily skimmings will amount to about 50 lb. (23 kg.) per day, or 300 lb. (135 kg.) in the week. Furnace dross has a salable value as such, and its price will depend upon its content of elemental aluminum and the condition of the secondary metal market.

Grading Melts

In what has gone before it has been shown how aluminum melting is either intermittent or continuous, and consideration is now given to various grades of furnace heats and the use of scrap aluminum in charges.

TABLE III. PERCENTAGES OF SCRAP AND PIG IN ROLLING INGOTS

Ingot Designation	Percentage of Pig	Percentage of Scrap
A	100 to 80	0 to 20
B	80 to 60	20 to 40
C	60 to 40	40 to 60
D	40 to 20	60 to 80
E	20 to 0	80 to 100

Aluminum-melting charges for ingot production are made up according to the quality of ingots desired, and they may vary more or less, depending upon local conditions, the amount and character of the scrap made in the plant, as well as upon the conditions existing in the aluminum pig and scrap markets. Rolling ingots may be designated by any suitable symbols, according to the percentages of contained scrap and pig metal. Thus, ingots may be designated as A, B, C, D and E, depending upon the relative proportions of scrap and pig in the furnace charges. Table III shows how the percentages of pig and scrap may vary, but the figures and the symbols are arbitrary; as a matter of fact, the relative percentages of scrap and pig may be anything from 0 to 100 per cent of each.

Strictly speaking, first-grade rolling ingots are understood to be ingots cast from an all-pig melting charge, or they may include ingots cast from a charge consisting of pig plus scrap originating in the manufacturer's own plant and of a composition not differing markedly from the composition of the pig. All-scrap ingots are made from an all-scrap charge. Usually varying amounts of scrap are charged together with pig metal.

All-pig ingots will have practically the same chemical composition as the original pig metal, but there is usually a higher silicon content due to reduction of SiO_2 from the furnace lining by the aluminum. With increasing percentages of scrap in the charge, the aluminum content of the ingots becomes lower and lower, and all-scrap ingots seldom, if ever, contain 99 per cent Al.

Copper, brass, iron, steel, etc., may become mixed with aluminum scraps, particularly the lighter ones; hence, on melting, zinc may be introduced, copper and iron will be increased, and other impurities may find their way into the resultant ingots, depending upon the nature of the contaminating materials. The common aluminum-mangenese alloy, containing about 1.50 per cent Mn, and employed for so-called "hard sheets," may also become mixed with aluminum scrap, with a consequent introduction of appreciable amounts of manganese on remelting. In a word, it is practically impossible to guard against the contamination of scrap under existing plant conditions. On the basis of a 99 per cent aluminum content for virgin pig, remelted scrap will rarely contain that much aluminum, and it usually contains about 98 per cent.

Influence of Impurities

The presence of certain impurities, in subordinate amounts, appears to cause no particular harm, at least so far as rolling is concerned. However, it is a fact that ingots cast from high scrap content charges, such as D and E in Table III, usually contain more occluded dross than A ingots; and sheets rolled from the former never appear to have so good a surface appearance as those rolled from A ingots. D and E ingots are rarely used for sheet rolling, and if used at all should be worked into strip rolled metal. The lower grade ingots will split more readily than the higher grade ones on rolling, but strip metal is drawn out rather than spread, so that D and E ingots may be utilized for this.

In commercial mill practice, furnace charges will be made up according to the grade and quality of the sheets demanded, whether strip is made or not, and whether specifications are called for or not. Specifications for sheet aluminum will be included later.

Pouring Practice

Generally speaking, the size of ingot to be poured will depend upon the size of sheets to be rolled, and this matter, knowing the scrap allowances for shearing, is one of simple mathematical calculation. Ingots are poured as a rule in the sizes tabulated in Table IV, but any size can be cast according to the requirements. In any plant, the ingot production is governed not only by the melting capacity but also by the number of available ingot molds, since a mold can be used only once every 30 min. on the average, unless provided with a water

TABLE IV. DIMENSIONS AND WEIGHTS OF ALUMINUM ROLLING INGOTS

Ingot dimensions, in.	Calculated weight[1] lb.	Actual average weight,[2] lb.
4 x 12 x 17	79.5	75.5
3.5 x 12 x 20	81.4	79.0
3.5 x 12 x 21	85.9	86.5
3.5 x 12 x 22	90.0	89.0
4 x 12 x 20	93.0	90.0
4 x 12 x 21	98.0	94.5
3.5 x 12 x 24	98.0	95.0
4 x 12 x 24	112.2	107.0
4.75 x 11.75 x 22	119.6	114.5
4 x 12 x 27	126.3	121.0
4.75 x 11.75 x 24	130.5	123.5
4 x 12 x 30	140.3	135.0
7 x 16 x 24	261.9	259.0
7 x 16 x 26	305.5	300.0
7 x 16 x 30	327.4	315.0
7 x 16 x 36	392.8	366.0

1 in. = 2.54 cm.; 1 lb. = 0.454 kg.

[1] Calculated for ingots of the dimensions indicated and based on specific gravity = 2.70

[2] The actual average weights given are based on figures obtained by weighing a number of ingots from a given set of molds. The actual weights are less than those calculated, because the molds did not have the exact dimensions given. Furthermore, when speaking of a 4 x 12 x 17-in. ingot, for example, reference is had to the inside dimensions of the mold into which the ingot was poured. Shrinkage on freezing, blowholes, occluded gas, variation in filling the molds, and the fact that the molds were not exactly the same size as the dimensions indicated for the ingots account for the apparent discrepancies.

circulating cooler, when it can be used every 9 or 10 min. Aluminum ingots are cast in cast-iron chill-molds of proper dimensions.

In ingot-casting practice, as carried out at present, the melting furnace, if stationary, is tapped by withdrawing a plug filling the tapping hole at the front of the furnace. The metal then flows down an iron runner into the pouring crucible. When the crucible (a No. 125 to No. 200 in size) is about three-quarters full, or contains sufficient metal to pour one ingot of the desired size, the tap hole is plugged, and the stream of metal is shut off. This plug consists simply of a conical iron tool with an iron handle, and a 50:50 dough-asbestos ball is stuck on the point of the cone. Pouring crucibles are also filled by ladling out the aluminum from the furnace through one of the doors, the ladle being supported on a swing. With the ladle ordinarily used, it requires three or four ladlesful to fill a crucible. This method of filling crucibles is to be regarded as bad practice, because there is more opportunity for dross to become tangled in the metal.

Whether the metal is tapped or ladled, the surface of the aluminum in the pouring crucible should be skimmed before pouring. The pouring crucible when filled is conveyed by hand, or on an overhead monorail with hoist, to an adjacent battery of ingot molds drawn up into position by a chain hoist. The molds are tilted at an angle of 70 to 90 deg. with the horizontal. Pouring is accomplished by allowing the aluminum to run into the tilted mold, and at the same time lowering the mold slowly back and down to its original vertical position, so that as the mold finally assumes this position pouring is complete, and the mold is full of metal. An even stream of metal should be maintained from the crucible to the mouth of the mold; as the mold is lowered, the crucible is raised, and in this way the required condition is maintained until the mold is full. This procedure is followed so as to avoid splashing, for the metal can thus be made to flow down one side and thus fill the mold evenly.

Correct Feeding of Iron Molds

Aluminum has a relatively high coefficient of contraction, and in order to avoid piping, the mold must be continually fed at the head until the entire ingot is frozen. Feeding is accomplished with a hand ladle by adding hot metal from the liquid aluminum remaining in the crucible. Aluminum freezes very rapidly in chill molds, so that feeding at the head must be fairly rapid in order to keep pace with the contraction. When the metal has frozen, the molds are knocked open, and the ingots are removed.

Ingots are sometimes rolled directly from the molds, but more often are allowed to cool and then preheated before rolling. That the latter is a more rational procedure will be shown later.

Iron molds, as already mentioned, can be used, on the average, about twice in an hour, unless they are water cooled by circulating water. If not cooled in this manner, cooling may be hastened, apparently without any ill effects upon the molds, by "swabbing" them inside and out with cold water. It is more advisable to have the molds provided with a circulating water-cooling attachment. Molds should always be swabbed out on the inside with water after pouring each ingot so as to prevent accumulation of "fuzz" and insure that the surfaces of the ingots will be smooth. A swab can be made by tieing a ball of rags on a stick.

Some idea of the output of an average ingot-casting plant may be derived from the following figures: With an equipment consisting of 24 molds of the 4 x 12 x 17 in. (13 x 30 x 43 cm.) size and two 5,000-lb. (2,300-kg.) melting furnaces, five men can cast about 200 ingots in a day of 10 hr. It may be assumed that there are two men working on the furnaces, one melter and one helper. The melter will be charged with keeping the heats in good condition; the helper may spend most of his time with the ingot-casting crew. With twenty-four molds set up in two batteries of twelve each, there will be one man on each battery of molds. These men will remove the ingots after pouring, swab out the molds, and prepare the molds for the next pouring. Two men will be used for casting the metal, and the furnace helper will tap the furnaces. Daily production will vary, of course, with local conditions. For example, if ingots are rolled directly from the molds, the casting should be so arranged as to keep pace with the rolling. As has already been intimated, rolling directly from the molds is a rather dubious practice, and, as will be shown later, is not to be recommended.

1.5 Per Cent Manganese-Aluminum Ingots

Before dealing with the mechanical treatment of aluminum, a little space will be given to a consideration of the production of 1.5 per cent manganese-aluminum alloy ingots. As has been mentioned above, an alloy of this composition is rolled for the purpose of making so-called "hard sheets." These sheets are rolled for particular purposes where more strength is required than substantially pure aluminum can provide.

This alloy is rather troublesome to make, mainly because of the wide difference in melting points of aluminum and manganese, the usual procedure being to employ a 25:75 Mn-Al alloy for the purpose of introducing the manganese. Such an alloy can be purchased in the market or made up in the plant; it is economical to make the alloy as needed if much 1.5 per cent manganese-aluminum sheet is to be rolled.

On the assumption that a 25:75 Mn-Al alloy is used for introducing the manganese, the procedure to be followed in the production of ingots is substantially this: On the basis of a 5,000-lb. (2,300-kg.) heat, part of the aluminum (pigs and scrap) should be first melted and superheated. Then an addition of the 25:75 Mn-Al alloy should be made; either all or part of the rich alloy may be charged at this stage. The bath should be thoroughly stirred and churned to insure alloying and to prevent segregation. Then more aluminum and more of the rich alloy (provided it has not all been put in) should be charged from time to time until the whole charge is liquid. It is advisable, in making a large heat of the 1.5 per cent manganese-aluminum alloy, to charge into the melting furnace approximately enough of the rich alloy to produce a final alloy of the composition desired, as may be found by simple calculation. On the supposition that a 5,000-lb. heat is melted, then 300 lb. (135 kg.) of the 25:75 Mn-Al alloy would be charged. Samples of the melt should be taken before casting and sent to the chemical laboratory, where the manganese content can be determined in 15 to 20 min. In general, it is better practice to aim for a slightly higher manganese content than that actually desired, and then reduce it by later additions of Al, rather than to have the Mn too low, because of the difficulty in incorporating manganese.

TABLE V. MELTING RECORD[1]

Month	Consumption of Metal in Pounds: Pig	Rolling-mill scrap	Utensil scrap	Baled scrap	Furnace scrap	Outside scrap	Total metal charged	Production in Pounds: Rolling ingots	Furnace scrap[2]	Dross[3]	Per cent loss[4]
January	57,871	64,182	5,375	2,701	368	995	131,492	128,925	356	1740	1.68

[1] Based on the performance of one 5,000-lb. gas-fired, open-flame furnace (1 lb. = 0.454 kg.)
[2] Furnace scrap includes drippings, splashings, sweepings, etc., in the melting room
[3] Dross was weighed as such; metallics vary from 30 to 60 per cent.
[4] The figures for per cent loss are based on calculations derived from the formula

$$\frac{\textit{Weight of total metal charged} - (\textit{weight of rolling ingots} + \textit{weight of furnace scrap})}{\textit{Weight of Total Metal Charged}}$$

The necessity of keeping accurate records for the melting room will be readily apparent, and in fact, no systematic cost finding system can be applied to the plant if the melting records are neglected. Since balance sheets are customarily drawn each month, it may be advisable to keep monthly melting records; the results of the day-to-day performance can be readily added and transferred at the end of each month. In devising any record for melting, it is well to be guided by the principle that simplicity will prevent confusion. The essential data will include the amount of metal charged, the amount of ingots poured, the dross weight, and the shrinkage. Metal charged should be classified according to kind, i.e., pig, rolling-mill scrap, fabricating scrap, furnace scrap, scrap purchased outside, etc.

Table V shows a year's record for one 5,000-lb. (2,300-kg.) furnace in the melting room of a plant which operated a rolling mill and a utensil plant, during which time both intermittent and continuous melting were employed. Consumption of metal in pounds refers to the amount of metal charged into the melting furnace; the metal charged is classified as pig, rolling-mill scrap, utensil scrap, baled scrap, furnace scrap and outside scrap. In the present record, pig was mainly in the form of 33-lb. (15-kg.) four-notch bars, but some 3-lb. (1.4-kg.) six-notch ingot was also charged; rolling-mill scrap was made up of sheet and slab shearings from re-squaring operations and of defective sheets; utensil scrap consisted of defective utensils and large scrap from the utensil plant; baled scrap was baled hay, chips and trimmings from the utensil plant; furnace scrap consisted of splashings, floor sweepings and drippings occurring in the melting room on casting ingots; and outside scrap was made up of scrap purchased from outside sources, and was in various forms of light scraps. Production refers to the output of the melting furnace, and is made up of rolling ingots, furnace scrap and dross. A month's collection of furnace scrap was recharged early in the subsequent month. Dross consisted of the scrapings resulting from cleaning out the furnaces and skimmings from the furnace heats. Strictly speaking, there is also some flue scrap, where fine particles of metal admixed with dross are blown into the flues and collect there. In the case in hand, flue cleaning was done only at long intervals, and during the year one cleaning yielded 1,176 lb. (534 kg.) of flue dust.

Since the true metallic content of the dross cannot be accurately estimated, due largely to the difficulty in sampling this material, figures for losses are rather uncertain. Various methods are used for determining the shrinkage on melting, none of which are entirely satisfactory.

Calculation of Losses

In Table V, the loss has been calculated from the formula

$$\frac{\textit{Wt. metal charged} - (\textit{Wt. metal poured} + \textit{scrap})}{\textit{Wt. metal charged}}$$

Other figures have at times been based on the formula

$$\frac{\textit{Wt. metal charged} - (\textit{Wt. metal poured} + \textit{dross} + \textit{scrap})}{\textit{Wt. metal charged}}$$

Figures derived from both formulæ are liable to be exceedingly erroneous, and it appears to be better to assume a definite metallic content for the dross. By so doing, a nearer approximation to the shrinkage can be obtained. Thus, if the dross contains say 40 per cent metallic aluminum, closer figures would result from the use of the formula

$$\frac{\textit{Wt. metal charged} - (\textit{Wt. metal poured} + \textit{scrap} + 0.40\ \textit{dross})}{\textit{Wt. metal charged}}$$

than would be obtained from the first two formulæ.

(Part III, dealing with ingot heating and mill calculation, will be published in our next issue.)

Four Billion Dollar Balance of Trade

The excess of American exports over imports in 1919 amounted to $4,017,000,000, a new record, according to a statement issued by the Bureau of Foreign and Domestic Commerce, Department of Commerce. Exports for 1919 totaled $7,922,000,000, as compared with $6,149,000,000, while imports were valued at $3,904,000,000, against $3,031,000,000 in 1918.

December exports amounted to $681,000,000, a falling off from the $741,000,000 recorded for November. Imports also fell off for December, the total being $381,000,000, as compared with $425,000,000 for November. Both exports and imports were higher than in December a year ago.

The imports of gold in 1919 amounted to $77,000,000, compared with $62,000,000 in 1918 and $552,000,000 in 1917. Exports of gold in 1919 jumped to $368,000,000 from $41,000,000 in 1918. In 1917 they amounted to $372,000,000.

No marked change was noted in the imports or exports of silver, receipts amounting to $89,000,000 and shipments to $239,000,000 in 1919.

Double Pipe Heat Interchangers*

A Study Establishing the Importance of the Factor of Film Velocity in the Helical and Straight Length Double Pipe Heat Interchangers—Effect of Varying Pump Pressure, Pipe and Overall Dimensions

BY GEORGE A. RICHTER

THE chemical engineer is vitally interested in experimental data giving information on the flow of heat from one fluid to another through metal surfaces. Although many papers have been written on this subject, there is still room for a vast amount of experimental work to confirm established heat laws and to pry further into unknown regions.

George A. Orrok gives an excellent review of published information on conductivity experiments in the 1910 volume of the *Transactions* of the American Society of Mechanical Engineers. Most of the work so summarized refers to the surface condensation of steam, and although some of the deductions listed may be applied directly to a liquid-to-liquid heat interchange, the conclusions reached must be studied with due reservation. A host of formulas have been presented by experimenters for surface condensation. It is very probable that discrepancies in their results do not point necessarily to inaccuracy in work, but may give evidence that there are other factors involved which have not been recognized.

Although the experimental work upon which this present paper is based concerns only double pipe heat interchangers, using hot and cold liquids, a brief résumé of heat transference in general may not be out of place.

Definition of Conductivity

Heat transference is conventionally expressed in terms of heat units transferred per unit of surface per unit of time per unit difference in temperature. In this country English units are employed. A given system has a certain conductivity (K) representing the number of British thermal units transferred per sq.ft. of surface per hr. per deg. difference in temperature between the hot and cold fluid. Mathematically this temperature difference is the logarithmic mean of the incoming and outgoing hot and cold liquid:

$$T = \frac{D_1 - D_2}{\log_e \frac{D_1}{D_2}},$$

where D_1 represents the difference in temperature at the beginning of the system and D_2 the difference at the end.

It is at best exceedingly difficult and probably impossible to cover all cases of such heat transference by means of a few well-selected formulas. A new condenser, or a surface heater of radically different design, always requires experimental investigation in order to learn more concerning the application of heat laws already in existence. Such investigation sometimes involves the fixing of new constants in equations already worked out for other types. Often it means the establishment of entirely new relationships.

*Read at the Savannah meeting of the American Institute of Chemical Engineers, Dec. 3-6, 1919.

Plant Considerations

The conductivity, or K, of a system is a function of the rate of heat transfer in that system. Often the value of K is all-important in the design of new cooling or heating installations. There are cases, however, where other factors are equally important. In general, the design of a new interchanger involves the following plant considerations:

1. Conductivity, or K, of various types of units.
2. Capacity of interchanger in total B.t.u. per volume of space occupied.
3. Amount of fluids to be pumped or moved in other ways.
4. Power required.
5. Limiting temperatures of incoming and outgoing fluids.
6. Construction and determining cost of material, practicability, resistance to corrosion, etc.
7. Intelligence required in operation.
8. Physical and chemical characteristics of fluid to be heated and cooled.

Each problem is apt to present other phases for consideration, depending upon requirements. Sometimes one factor of those enumerated above is of paramount importance. Factors 2 to 8 as listed demand the application of engineering sense and judgment. The conductivity factor cannot be calculated from theoretical principles, and consequently most of the experimental work on cooling and heating systems is concerned with that end of the problem.

Effect of Velocity of Liquor

If the total cost of introducing or abstracting a given number of B.t.u. in a system is to be minimized, compensatory advantages and disadvantages must be carefully weighed. For instance, the engineer must decide whether it will pay him to raise the conductivity by increasing the velocity of the liquid. In order to make such a decision he must have experimental data showing the effect of liquor velocity on power consumption of pump as well as on conductivity realized. He knows in general that raising the velocity either of the hot or of the cold liquor will increase the conductivity. He also knows this increase in conductivity is not a straight line function of the power consumption involved. The above example is merely one of several which confront the engineer on any new cooling or heating installation. The more data available the less guesswork and worry result.

Several investigators have established equations showing the effect of velocity of liquor on conductivity. Their equations vary quite considerably. In general, they express conductivity as a function of the nth root of the velocity of liquor. This value n is usually different for different types of condensers, and conse-

quently an equation cannot be taken without a thorough study of conditions under which this equation was established. Factors of which we have little knowledge may cause very great changes in conductivity with but slight changes in design.

Importance of Film Velocity

For example, we may state with some assurance that the so-called film velocity of water has marked effect on conductivity realized. But what determines film velocity?

Tabulated experimental results indicate rather forcibly that a very slight change in design of heat interchanger may cause an almost unbelievable change in conductivity, and there appears to be no better explanation than that there has resulted a greater film velocity although the average velocity has not been altered. Marked differences in formulas established in the past and in our own work emphasize the necessity of more intense study and further experimental investigation.

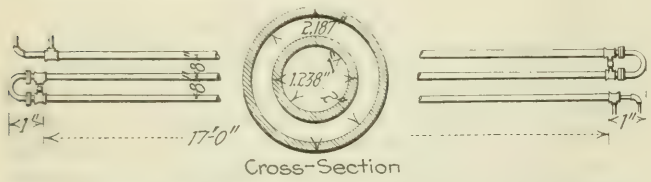

FIG. 1. VIEW AND CROSS-SECTION OF FLAT COIL COOLER

Scope of Investigation

As stated before, the work discussed in this paper concerns mainly the efficiency of so-called double pipe heat interchangers. We were interested in a system represented by a liquid-to-metal-to-liquid heat transfer. Inasmuch as the problem involved cooling acid liquors, a lead inner pipe was enclosed in a wrought iron jacket pipe. The procurement of maximum thermal conductivity was necessary in order to conserve lead pipe and to use a minimum amount of cooling water.

Although several designs of coolers were constructed for experimental data, this paper confines itself to a comparison of two types, the helical and the straight length. Sufficient data were accumulated to establish direct relationships, which may to a limited extent be used in considering other designs. It is to be noted, however, that although the factors which influence conductivity in these tests may be used qualitatively for other types of coolers, no quantitative relationship should be assumed.

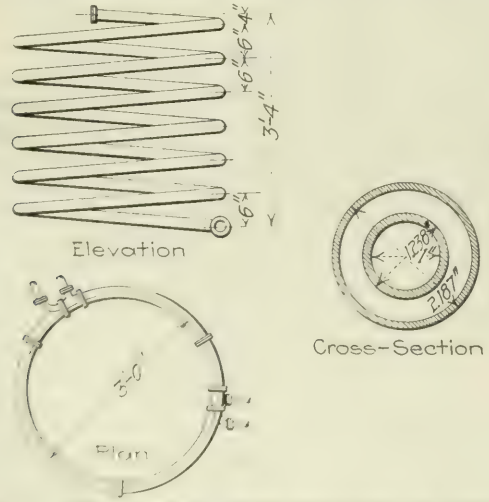

FIG. 2. VIEWS AND CROSS-SECTION OF SPIRAL COIL COOLER NO. 2

Final Objects

Tests were carried out with three objects in view: first, to determine whether a double pipe coil put into the form of a helix would give higher conductivity than one with the same pipe dimensions put into 20-ft. lengths; second, to learn more regarding the effect of varying the diameters of the inner pipe of a helical cooler; third, to study the effect of changing the overall dimensions of a helical cooler.

Apparatus Used

The units were set up as follows:

1. A 60-ft. 1-in. lead pipe within a 2-in. wrought iron pipe arranged in three 20-ft. lengths. The general assembly and a cross-section of the double pipe is shown in Fig. 1.

2. A 60-ft. 1-in. lead pipe within a 2-in. wrought iron pipe wound in the form of a helix and connected by flanges as illustrated in Fig. 2.

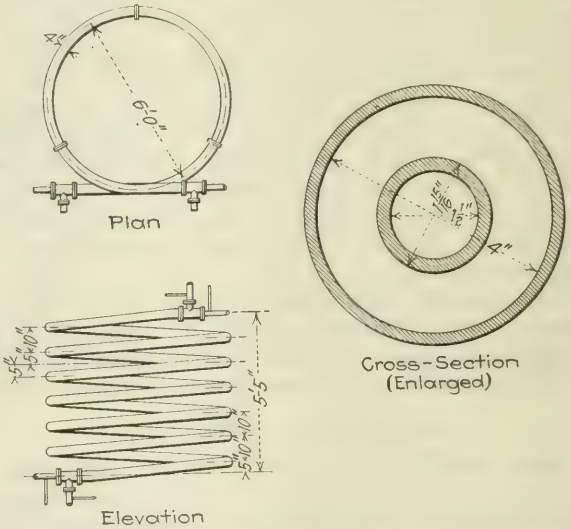

FIG. 3. VIEWS AND CROSS-SECTION OF SPIRAL COIL COOLER NO. 3

3. A 120-ft. 1½-in. lead pipe within a 4-in. wrought iron pipe flanged and wound in the form of a helix as shown in Fig. 3.

4. A 120-ft. 2-in. lead pipe within a 4-in. wrought iron pipe wound in the form of a helix in exactly the same way as represented by Fig. 3.

Each of these four coolers was set in place in very much the same way. The method for determining volume of liquor, temperatures, and velocities is shown diagrammatically by Fig. 4. Before each test, the hot liquor to be cooled was heated in a tank to the desired temperature by means of live steam. The volume delivered during the test was measured directly by drop of the level of the liquor in this tank. Cold water was pumped through the jacket and delivered over a weir for measurement. Pump pressures were regulated by means of a rheostat and thermometers installed at parts needed.

Usually a series of runs was made with different initial temperatures, in order to determine whether the temperature difference of hot and cold liquor materially influences the conductivity. During the test, readings were taken of the volumes and temperatures

of ingoing and outgoing liquor every 30 sec. The first readings were recorded after the system had been operating one full minute, in order to allow time for equilibrium to be established. Knowing the cross-section of lead pipe and wrought iron pipe, the velocities could be calculated.

Variables Studied

The following factors influencing the conductivity in each case were studied:

1. Velocity of cold jacket water.
2. Velocity of hot water within lead pipe.
3. Change in conductivity due to a change in temperature.

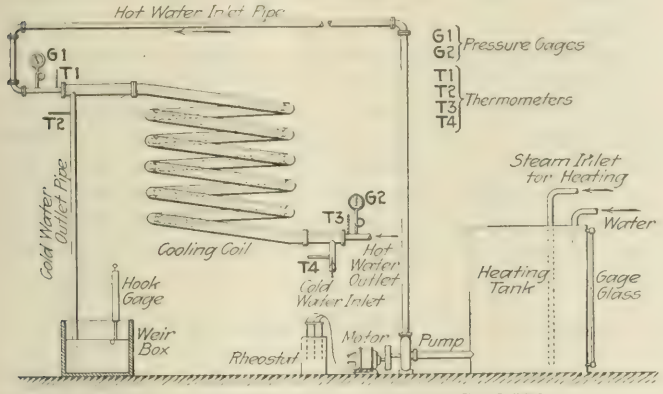

FIG. 4. DIAGRAM OF COOLING UNIT

4. Pressure of hot and cold water entering the system.
5. Change in conductivity due to change in design of cooler.

The tabulated results and data obtained in this way are shown by Charts I to VIII.

Helical vs. Straight Length Cooler

Chart I illustrates the change in conductivity of No. 1 and No. 2 coolers with change of velocity of hot water, the cold water velocity being held practically

Velocity of Cold Water in Feet per Second

CHARTS I AND II. CHANGE IN CONDUCTIVITY WITH WATER VELOCITY

constant. Chart II pictures the change in conductivity taking place with different cold water velocities, keeping the hot water velocities practically constant. Inasmuch as there is no change in pipe dimensions, the differences in K represent the effect of curvature in the pipe.

Both charts show a substantial increase in K as the velocities of liquids are increased. This was to be expected. At corresponding velocities, the helical cooler gave in each case a higher K, indicating that the pipe curvature does increase the effectiveness of heat transfer. Chart II represents runs made with a rather high (17 ft. per sec.) velocity of hot water, and consequently the entire curve lies in a region higher than the curves shown in Chart I, which represents runs with a constant cold water velocity of only 6.1 ft. per sec. Moreover, the curves in Chart II are steeper, showing a greater mathematical change in K with change in cold water velocity.

Molier calculated from Joule's researches (*Z. Ver. deut. Ing.*, 1897, No. 6) that the conductivity of heat from liquid through copper to liquid could be represented by a formula (English units)

$$K = \frac{61.5}{\frac{1}{1 + 3.3V_h^{0.5}} + \frac{1}{1 + 3.3V_c^{0.5}}}$$

where V_h and V_c represent velocity of hot and cold liquids respectively. Such an equation means that either hot or cold water velocity increments have equal effects in changing conductivity obtained. This is probably true for some forms of coolers, but is dependent upon the design.

Equations were deduced from the experimental data

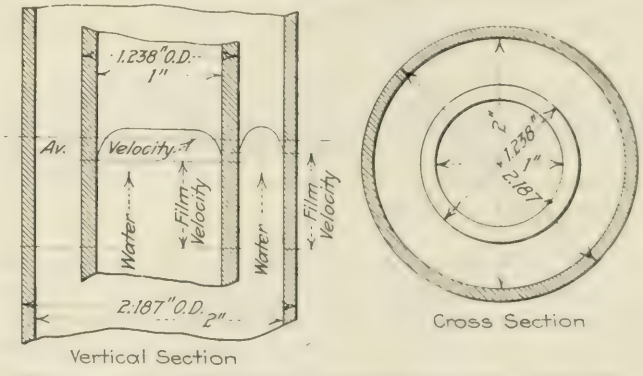

FIG. 5. FILM VELOCITY IN DOUBLE PIPE COOLER

on coolers 1 and 2 and are put into similar form as taken by Molier's equation.[1]

Cooler 1 (straight pipe).

$$K = \frac{62.7}{\frac{1}{1 + 5V_h^{0.57}} + \frac{1}{1 + 5V_c^{0.57}}} \qquad (1)$$

Cooler 2 (small helix).

$$K = \frac{76.2}{\frac{1}{1 + 5V_h^{0.6}} + \frac{1}{1 + 10V_c^{0.5}}} \qquad (2)$$

It is to be noted from these formulas that with each cooler an increase in cold water or jacket velocity can have a greater effect in increasing K than a corresponding increase in hot or inside water velocity. This may be due to a greater actual increase in film velocity of water in the jacket than that obtained by the same increase of average velocity of liquid within the inner coil, and this greater increment may be caused by the obstruction formed due to the position of the inner pipe. In order to get a clear mental picture of this explanation offered, it will be well to consider a sketch (Fig. 5) drawn to represent and distinguish average velocity and film velocity in the same pipe or tube.

[1] See Appendix for explanation.

The diagram shows a cross-section of a double pipe cooler, water flowing in the direction of the arrows. The average velocity in both jacket and in the coil is equal and represented by a.v. We have reason to believe that it is not this a.v. which determines the *K* of the system, but rather the film velocity, and this f.v. is evidently dependent upon the cross-section of channel as well as the a.v. of total liquid flowing through. Thus, we would state that the smaller the cross-section of the pipe or other channel, the higher will be the actual film velocity for a given a.v. As inferred above, quadrupling the a.v. may increase the film velocity of the inner coil by 2, whereas the same increase of average velocity in the jacket may raise the film velocity of

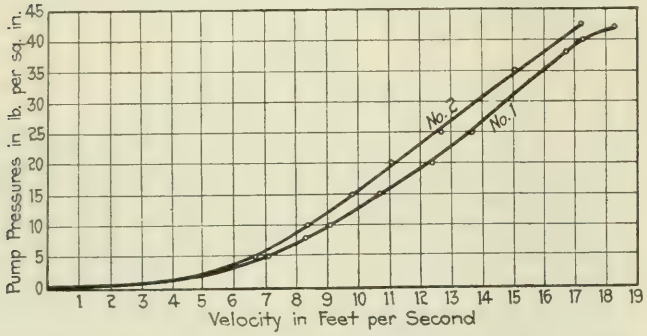

CHART III. VELOCITY IN INNER COILS WITH DIFFERENT PUMP PRESSURES

the jacket water by 2.5. We do not know whether *K* is *directly* proportional to film velocity. If it is, then by reversing the computations used, one could actually calculate the effect of increased a.v. on increased f.v., or solve the equation:

$$\text{f.v.} = f\ (\text{a.v.})$$

In imagining the flow of water through a helical and through a straight cooler, it is not difficult to picture a higher f.v. for a given a.v. in the case of the helical cooler. The a.v. is calculated from actual gallons delivered and does not take into account the path of each particle of water as it travels through the cooler. The helical form would naturally add rotary as well as linear motion and result in greater total velocity of water film next to the surface. The data plotted confirm such a prediction. The conductivities obtained with the helical form of cooler averaged from 10 to 20 per cent higher than those obtained with the straight cooler.

The question of power arises. The rotary motion evidently causes more friction, and would necessitate a greater pump pressure to deliver a given capacity of water. Chart III shows the pump pressure plotted against average velocity with both coolers.

In the operating region of the chart the straight cooler shows a greater a.v. at a given pressure of about 1 ft. per sec. Referring back to Charts I and II, it will be noted that it would require a 4 to 5 ft. difference to compensate for difference in *K* found.

There are other analogies and differences which may be pointed out in reviewing the data from which these curves were drawn, only one of which will be considered here. For many years experimenters have made attempts to find relationships of *K* and temperature difference in a given system. The curves as plotted in Charts I and II were based on data which include at least four runs at each point, the initial water temperature ranging from 110 to 180 deg. F. A careful survey of the data[2] indicates that in general the *K* goes up very slightly with the initial temperature of hot H_2O. Inasmuch as the initial cold water temperature was held practically constant during any given series, an increase in initial hot water results in a greater average hot water and cold water temperature of both liquids passing through the apparatus. The only explanation we have to offer for a slight increase in *K* with higher average temperatures in the system depends on the fact that the viscosity of water decreases as the temperature is raised. It is probable that the film velocity for a given a.v. increases as the fluidity of the liquid increases, thus allowing greater conductivity. Graphically, we may represent in an exaggerated way the film velocity of water at three different temperatures. (Fig. 6.)

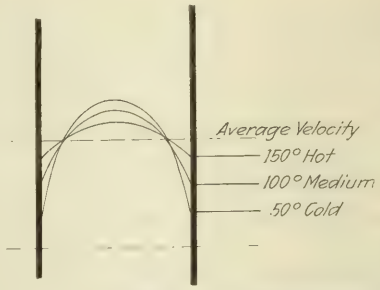

FIG. 6. TEMPERATURE EFFECT ON FILM VELOCITY

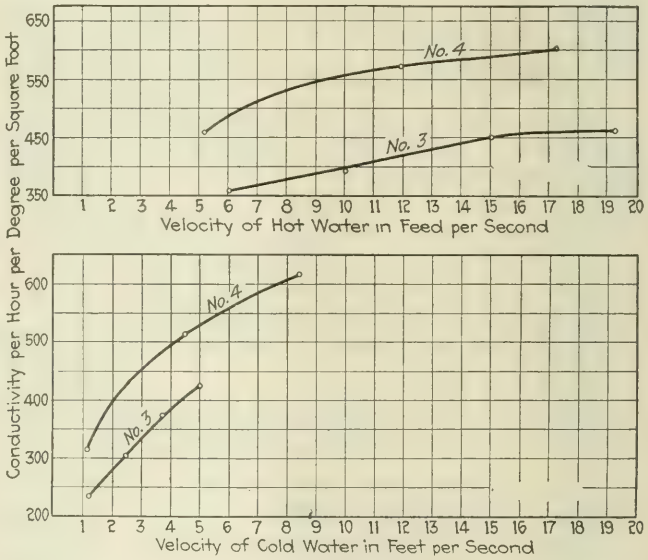
Large vs. Small Inner Pipes in Helical Cooler

As outlined above, work carried out in the investigation allowed us to learn more concerning the effect on *K* of changing the diameter of the inner pipe and incidentally to speculate further on factors which influence film velocity. The units employed for the work were larger in size. Cooler 3 consisted of 120 ft. 1½-in.



CHARTS IV AND V. RELATIONSHIPS OF WATER VELOCITIES AND CONDUCTIVITIES

lead pipe inside a 4-in. wrought iron pipe in the form of a helix 6 ft. in diameter. Cooler 4 substituted a 2-in. lead coil for the 1½-in. coil. Otherwise there was no difference. Similar series of runs were conducted as in the case of the smaller coolers. Charts IV and V show relationships of water velocities and conductivities.

These charts picture consistently the greater *K* obtained with the No. 4 cooler at average liquid velocities equal in each case. The magnitude of the differences rules out all chance of accident or inaccuracy. Our first hope was to explain this increase by some applica-

[2]Data were given in Appendix but are not included here.

tion of the film theory, and although subsequent work may confirm or reject our explanation, we will offer it for what it is worth.

It is reasonable to suppose that an increase in internal pipe diameter will, by contracting the jacket space, increase the ratio of $\frac{\text{f.v.}}{\text{a.v.}}$ in the jacket. Granting this, the greater will be the K, as far as determined by jacket velocity, as we increase the internal pipe diameter. Conversely, as the inner pipe diameter is increased, we should expect a lowering in ratio $\frac{\text{f.v.}}{\text{a.v.}}$ within the inner coil, which in turn would counteract

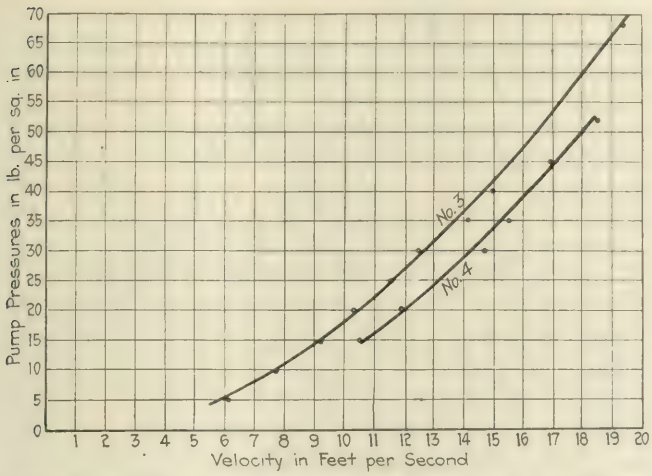


CHART VI. VELOCITY IN INNER COILS AS AFFECTED BY PRESSURE

to a certain extent the jacket water ratio. Experimental results apparently prove that this compensating effect is only partial, which means that for a given increase in cross-sectional area of the inner coil, the f.v. increases much more in the jacket than the f.v. decreases in the inner coil.

Chart VI illustrates the changes in average velocity of hot water with change in pump pressure for both No. 3 and No. 4 units. Although no data are available to cover the point, it is reasonable to suppose that similar curves for jacket water velocities would be reversed.

The curves plotted on Charts IV and V may be represented by equations.

$$K \text{ (No. 3 cooler}^3\text{)} = \frac{57.5}{\frac{1}{1 + 5V_h^{0.57}} + \frac{2.60}{1 + 10V_c^{0.57}}} \quad (3)$$

$$K \text{ (No. 4 cooler)} = \frac{80.0}{\frac{1}{1 + 5V_h^{0.60}} + \frac{2.60}{1 + 10V_c^{0.50}}} \quad (4)$$

At zero velocity of hot and cold water, No. 3 cooler (by computation) has a conductivity of 15.95, whereas No. 4 cooler would show K equal to 22.2. It is of interest to note that Molier's equation for zero velocities gives a value $K = 30.75$.

Small vs. Large Helical Heat Interchangers

In the above we have attempted to draw comparison between a straight pipe and helical cooler; also between helical coolers of different inner pipe diameters. It may be instructive to compare results obtained with the small No. 2 helical and large No. 3 and No. 4 helical units.

Charts VII and VIII show the characteristics of these three coolers grouped for comparison.

It is noted that No. 4 cooler gives highest K values, with No. 2 cooler ranking a close second. No. 3 unit is appreciably lower in K. The difference in pipe diameters as well as diameter of entire helix makes it difficult to theorize on similarities and differences.

We will, however, tabulate certain relationships which may throw some light on the subject. If $x =$ the distance from the inside surface of the jacket pipe to the center of the annular channel and $y =$ the inside radius of the inner coil, then for each of these coolers:

$$\text{No. 2} \ldots\ldots \frac{x}{y} = 0.48$$

$$\text{No. 3} \ldots\ldots \frac{x}{y} = 0.687$$

$$\text{No. 4} \ldots\ldots \frac{x}{y} = 0.406$$

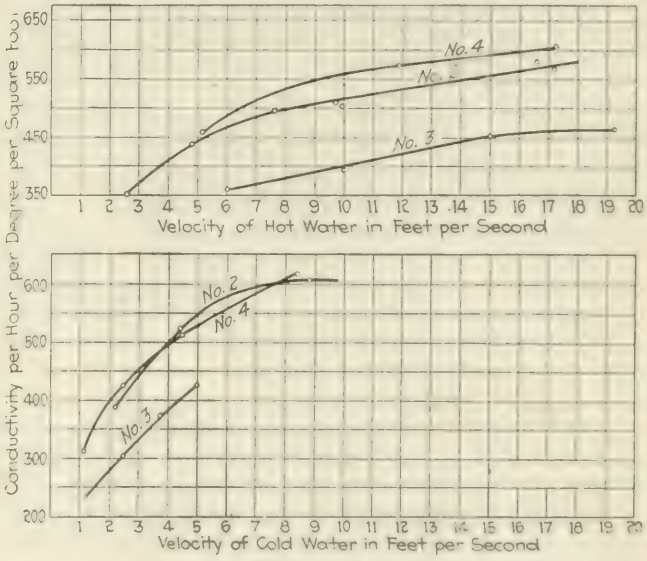
Referring to Charts VII and VIII, we note that the conductivities increase inversely as the ratio listed. This appears to be in accordance with a theory advanced earlier in the paper; viz., that a narrowing in jacket area has greater effect in increasing film velocity than a corresponding enlargement of inner tube cross-section would have in decreasing the film velocity.

Equation 2 and equation 4 show the same close relationship as pictured by the curves covering No. 2 and No. 4 coolers.

Summary

1. A double pipe heat interchanger in the form of a helix gives a marked increase in K over the same tubular parts put into the form of straight pipe lengths.

2. The film theory may account for this difference in K obtained.



Velocity of Hot Water in Feet per Second
No. 4
No. 3
Conductivity per Hour per Degree per Square foot
Velocity of Cold Water in Feet per Second
No. 2
No. 4
No. 3

CHARTS VII AND VIII. CHARACTERISTICS OF THREE TYPES OF COOLERS

3. The increase in pump pressure required with the helical unit is small in comparison with the added increase in thermal efficiency.

4. Conductivity in all cases apparently increases slightly with increase in average temperatures in the system. This may be due to an increase in ratio of $\frac{\text{f.v.}}{\text{a.v.}}$ as is explained in the contents above.

5. A helical cooler consisting of a 2-in. pipe within a 4-in. pipe gives higher conductivity than a correspond-

ing cooler equipped with a 1½-in. inner coil. A reason is offered for discussion.

6. Conductivities in helical coolers appear to vary inversely as the ratio of distance from inside surface of jacket pipe to center of jacket channel, to the radius of inner coil.

The writer acknowledges with thanks the valuable assistance of Frank M. Jones, who carried on the actual experimental work.

Appendix

Method

Water was heated to the desired temperature in a large iron tank by means of live steam. A centrifugal pump, motor driven, circulated the hot water; the velocity being regulated by means of a rheostat. The amount of water pumped out of the tank was measured by means of the drop in a gage glass.

Cold water was obtained from the river and its velocity regulated by a valve. Its flow was measured by means of a weir and hook gage.

Temperature changes were observed through four thermometers directly immersed in the flowing liquids. Melted sulphur was used to seal these in the various apertures. The thermometers were placed as near the inlets and exits of the cooler as possible. Runs were made at temperatures approximating 110, 130, 150, 170 deg. Fahrenheit scale.

Data on Apparatus Used

Tank—Height 5 ft. 6 in., diameter 4 ft. 7 in., capacity 677 gal. Water heated by live steam. Graduated water gage on side to measure outflow.

Pump—Lawrence, vortex 1½ in. discharge, single side suction, gage 5 in. from discharge to measure pressure.

Motor—Westinghouse 5 hp. constant speed, 60 cycle, two phase, 440 volts.

Weir Box—Length 12 ft., width 1 ft. 4 in., depth 1 ft. 3½ in.; contracted type, crest length 4.87 in., sharp crested. Channel of approach lined with tin, two vertical baffle plates serving to lessen surging.

Hook Gage—Of brass, reading to $\frac{1}{100}$ in.

Remarks—No. 1 straight cooler consisted of three 20-ft. lengths of 2-in. iron pipe containing 1-in. lead pipe. A surface of 36 in. of lead pipe (at the two ends) was exposed to the air and not affected by the cooling water. The under surface of the lead pipe was beaded at intervals to center it.

No. 2 helical cooler consisted of several sections of iron pipe bent to form a helical form. Three sections constituted one turn and were united by flanges. The overall dimensions were 36-in. diameter and 40 in. high. The lead coil was likewise beaded (or provided with lugs) at intervals to center it.

No. 3 helical cooler was similar to No. 2 except that 4-in. iron pipe was used for a jacket; three flanged sections to a turn; nineteen sections in all (or 6⅓ turns). The inner lead pipe was not beaded (or "lugged") but merely laid loosely inside the jacket.

No. 4 helical cooler had the same jacket as No. 3 but contained a 2-in. instead of 1½-in. lead pipe.

Calculations

Mean Temperature Difference.—The logarithmic mean was taken according to the formula (for counter-current).

$$T = \frac{(t_1 - t_4) - (t_2 - t_3)}{\log_e \frac{(t_1 - t_4)}{(t_2 - t_3)}}$$

where T = mean T. diff.
t_1 = initial hot water temperature.
t_2 = final hot water temperature.
t_3 = initial cold water temperature.
t_4 = final cold water temperature.

Conductivity

K, the conductivity constant, or B.t.u. extracted per hr. per deg. F. per sq.ft. of surface, is determined by:

$$K = \frac{A \times B}{T \times D}$$

Where A = lb. of hot water flowing per hr.
B = drop in temperature of hot water $(t_1 - t_2)$.
T = mean temp. difference.
D = sq.ft. of cooling surface.

Velocity

$$V = \frac{\text{cu.ft. per sec. flowing}}{\text{cross-section of pipe (in sq.ft.)}}$$

Weir

The weir flow was calculated from the well known Francis formula:

$$Q = 3.33(l - 0.2h)h^{1.5}$$

where Q = discharge in cu.ft. per sec.
l = width of notch, in ft.
h = height of water above notch level, in ft.

Empirical Equation of Velocity—K Curve

Since the velocities of both hot and cold water are independently variable, the desired equation connecting K with water velocity will contain three variables. In the cases in which one velocity was held constant while the other was varied, and then *vice versa*, the relation of hot and cold water velocities to K can be studied separately. The simplest way to do this is to plot on logarithmic paper values of K against those of the variable velocity, which tests for a relation of the form $K = AV^b$, where A and b are constants, or indirectly also for the similar form $K = AV^b + C$, where C is also a constant. In the former case the graph approximates a straight line, in the latter a curve which is concave upward if C is positive, downward if C is negative. The experimental data give a graph which is a curve concave downward; this is an absurd result physically, since it means that at zero velocity K is negative. Another form of equation should be sought.

The form which is suggested by Hausbrand ("Evap. Cond., & Cooling App." Revised Ed., p. 305), namely,

$$K = \frac{1}{1 + 3.3V_h^{0.50}} + \frac{1}{1 + 3.3V_c^{0.50}} \text{ (English units)}$$

has been found to satisfy the experimental data quite accurately, given slight changes in some of the numerical constants. An equation as this cannot be directly fitted to data, and a method of "cut and try" until the errors are below the experimental limit of accuracy is the only available method; on this account the constants are mainly round numbers, and the fit is not as close as might result from some method of direct solution.

Political and Commercial Control of the Nitrogen Resources of the World—III

A Review of the Economic Nitrogen Industry Outlook: Chilean Nitrate, Nitrogen Fixation, Byproduct and Organic Nitrogen and Byproduct Ammonia—Bibliography of Recent Literature on the Nitrogen Industry*

By CHESTER G. GILBERT†

THERE is no import duty on nitrogen, nor is there likely to be any, for nitrogen is an important cog in the mechanism of food supply, and the peace-time emphasis, reversing the war-time order, is primarily on cheapness and only secondarily on the point of origin. Accordingly, looking ahead, the American market conditions, once world trade is fully restored, are due to reflect the world conditions. As indicated in Fig. 4,[1] the sudden ending of the war with its calling off of the military requirements which had been building up steadily since even before the outbreak of hostilities in 1914, left the world with a producing capacity 30 to 40 per cent above normal. To what extent this apparent overproduction, amounting to about half a million tons of nitrogen, will prove real is impossible to foretell; not all of it certainly, for under the stimulus of a food shortage the curve of normal consumption will doubtless bend upward. On the other hand, however, there is the producing capacity of the plants not yet in operation to be taken into consideration. Whatever may be the capacity of agriculture to absorb from the surplus, it cannot be expected to take up the full amount immediately or without special inducement. The inference follows that price and production will come down to stimulate and co-ordinate with the increase in demand. Where the meeting point will be between the upcurve of demand and the downcurve of production it is impossible to predict. It is of interest, however, to figure in review on how the three types of industrial source, the natural, the byproduct and the fixation types, are equipped for the evident strife of competition implied in the situation.

Chilean Nitrate as Competitor of the Nitrogen Fixation Industry

With the development of fixation, there have been a lot of unfounded statements to the effect that the day of Chilean nitrate is passing. Whenever a synthetic development comes to the fore, a peculiar fallacy of reasoning is indulged in which ignores the fact of inherent natural worth, disregards the inescapable cost of its duplication, and regards the synthetic achievement as giving open sesame to the natural treasure. By way of substantiation in the case of nitrogen, the cost of producing Chilean nitrate is high, amounting to around $30 per ton. This, however, is largely contributed to by the unsystematized crudity of the operations, by the high export tax, and by over-capitalization. But these, it will be observed, are variable factors, susceptible of indefinite modification in keeping with the need. Chilean nitrate has never made any pretence of competing against byproduct nitrogen with its advantages in the way of low incidental producing costs and proximity to the market. The discrepancy between the byproduct supply and the total demand for nitrogen has all along comprised the field of opportunity opening to Chilean nitrate. In this its only noteworthy competitor is the fixation industry.

Variable Factors Affecting the Cost of Nitrogen Fixation

The fixation sources are impossible of analysis on a definite basis of cost. Too many variable factors and uncertainties are involved. Repeated attempts have been made, but all they have served to bring out is that under certain conditions, as for instance cheapness of power supply, and for certain purposes, one form of project has an apparent margin of advantage over another, and vice versa for other conditions, but that at best the cost of production, if not actually prohibitive, is dangerously close to the normal pre-war price of fixed nitrogen. Back of it all is the fact that fixation has to deal with the problem of overcoming the native chemical inertia of nitrogen, and the problem has not yet been solved at all convincingly. Always the solution advanced has called for some special measure of relief from industrial competition, whether natural as in the case of the Scandinavian power supply, or political as in the case of the American and German projects.

Prospects for an Economical Nitrogen Fixation Industry

Fixation has been widely heralded of recent years as due not only to emancipate the world from its dependence upon the Chilean source, but to reduce materially the cost of nitrogenous fertilizer, hence the cost of food production, to the marked betterment of living conditions as well. In its promise of political and economic betterment in one, it has claimed the attention of all. However, the claim of special economic advantage coming from an industry barely, if at all, able to meet conditions even as they are has been overdrawn. This does not aim to imply that there is nothing but failure ahead for fixation in the test of competition. It has its possibilities of development into something commercially and economically as well as politically worth while, but the existing hothouse order of upgrowth is unquestionably due for a lot of training down, and much that is worthless is as certainly due to go. The American developments have a particularly inauspicious economic setting in the prevailing scale of costs. The only saving alternative for them

---

The basis of this article by Mr. Gilbert was issued in mimeographed form for Government use only as one of the Political and Commercial Geology Series prepared under the direction of J. E. Spurr, to whom book rights are reserved.

*For Parts I and II see CHEM. & MET. ENG., vol. 22, Nos. 10 and 11, March 10 and 17, 1920, pp. 443 and 501.

†Curator of Mineral Technology, U. S. National Museum.

[1]See CHEM. & MET. ENG., vol. 22, No. 10, p. 447.

would seem to be in one form or another of Federal provision for their continued support on some such basis as that on which they were projected, and this is unlikely, for there is no apparent reason. True, lowered nitrogen costs tend to make for a lowering in the cost of foodstuffs, but so, for that matter, would a lowering in the cost of agricultural implements, and any arguments that apply in the case of nitrogen apply as equally for potash, for phosphate, for agricultural implements, for coal; in fact, for industry in general.

Outlook for the Byproduct Nitrogen Development

With reference to byproduct nitrogen the situation is very different. In general, the byproduct sources are of an order such that they were not materially affected one way or the other by the war, and consequently are not due to be materially affected in the process of readjustment, except in the case of coke-oven ammonia, where the temporary slump in the steel industry will result in a temporary slump of probably 15 to 20 per cent from the 1918 output. Of special significance in connection with what lies on beyond for the byproduction of nitrogen is its relationship to the progress of industrial co-ordination. The whole current trend of industrialism as represented, integration, volume production, and the like, is actuated in the interests of co-ordination and the overcoming of lost motion; and nitrogen comes in for an important share in these developments.

Outlook for Organic Nitrogen Development

With reference to the organic group of compounds, the outlook for the future is as uncertain as the actual conditions of today. The centralized development of meat-packing, of animal-rendering establishments, and of cotton ginning gave rise in their time to highly important recoveries of nitrogenous waste; but with the forward progress of developments this usage in turn is giving way to a more advanced order. Cottonseed as a fertilizer is giving place to a cottonseed products industry; tankage as a fertilizer is giving place to the artificial compounding of animal food; horses, an important contributor of agricultural nitrogen in times past, are yielding much of their place in the sun to the automotive engine. Meanwhile, with the factor of dilution to be overcome, our sewage disposal is employed to pollute streams and destroy the fish supply instead of being put to useful ends. So it goes. Developments are on foot that lead in both directions, and there is no telling how the balance is due to shift. Probably the best guess is that relatively at least it will be downward rather than upward.

Outlook for Byproduct Ammonia

The outlook for byproduct ammonia is more definite. Ammonia is the end point of material refinement, so here the nitrogen developments hold all they get rather than going on to lose out again in a further refinement of usage, as in the case of the organic group. The output has increased consistently and rapidly, owing to the transition from beehive to byproduct coking operations, to the progress of centralization and co-ordination—in other words, with reference to coke manufacture. Even now, less than half of the coal coked is treated in the retort oven; but the beehive oven is out of the line of progress and is due to be entirely displaced. Also, the industry is still expanding as the process of transition with its separate potentiality for doubling the present output of coal-product ammonia goes forward.

So far, the recovery of byproducts in connection with the use of coal has been confined in the one direction of coke making, along with the analogous procedure of gas manufacture. But the development which has thus started in the coke industry will not stop there. The loss of motion resulting from lack of co-ordination in the use of coal is just as great in other directions as in that of coke making, and the advantages of integral usage may confidently be expected to assert themselves. Already projects of the kind are coming under serious contemplation in proposals such as those for furnishing gas to cities, for employing byproduct operations located at the mine in support of the waning natural gas supply, and for integrated heat, light, and power projects operating on coal with byproduct recovery. Meanwhile, the motor-fuel situation is suggestive of interesting developments ahead. There is every reason to believe that the petroleum resources cannot continue to meet the growing demand, in fact, that the occasion for support is already at hand. Whatever the nature of these supporting developments, whether they take the form of a shale oil industry or what, it seems certain they will usher in an important source of byproduct nitrogen.

Summary

Fig. 3 summarizes the American situation with reference to chemical nitrogen, as does Fig. 4 in less detail that for the world. Organic nitrogen is omitted, partly because of the lack of information, partly because the issues more directly involved in the situation as it stands are those of chemical nitrogen.

Polish Salt Resources and Production

Rock salt is one of the most important natural resources of the new State of Poland. The production of salt in Polish territories just prior to the war was approximately as follows: Former Austrian Poland (Galicia), 141,215 metric tons; former German Poland (Poznania), 81,269 tons; former Russian Poland, 3,007 tons; total, 225,491 tons.

There is no doubt that these Polish salt deposits are capable of much more intense exploitation and, under proper organization, they could probably become the base for several branches of the chemical industry. This is one of the Polish industries wherein American capital would probably be welcomed at the present time.

Galicia also possesses at Kalusz the only potassium salt mines, besides those at Stassfurt, Germany, and a company has recently been formed to exploit this deposit. These Kalusz salts are composed chiefly of kainite and sylvite. The production of kainite, which amounted in 1893 to 4,000 tons, had risen in 1913 to about 17,500 tons, valued at $47,000. This deposit also was worked before the war by the Austrian Government, and it is hoped that now, under private initiative, it will become a considerably greater source of revenue.

American Beet Sugar Industry

IN ADDRESSING the Detroit Engineering Society on Jan. 23, Martin J. Kermer, chief engineer of the Cannon-Swenson Co., Chicago, spoke at length on processes employed in refining and economic features surrounding the sugar industry at present.

The total world production of sugar for 1919, expressed in terms of refined, is approximately 16,500,000 tons of 2,000 lb. each. Of this, the United States produced 915,000 tons, of which 795,000 tons were beet and 120,000 tons were made from cane. In other words, the United States produced approximately 5½ per cent of the world's supply. In regard to our consumption, we used last year approximately 4,000,000 tons, or 22,200,000 lb. per day, or 76 lb. per capita per annum. We are, therefore, consuming one-fourth of the world's production. We are producing approximately 23 per cent of what we consume. Another 24 per cent comes from Hawaii, Porto Rico and the Virgin Islands; while the remainder, over 53 per cent, comes from the Philippine Islands, Cuba, and foreign countries.

Consumption per Capita

It is interesting to note that from 1865 up to 1914 our consumption of sugar per capita per annum has gradually increased from 18 to 89 lb. Ever since the war started this consumption has been reduced year by year due to the shortage of production, which necessitated our restrictions. Today the world's production is 2,800,000 tons less than it was in 1914. If we consider the annual increase of consumption per capita for this country from 1900 to 1914, it is safe to say that we would have reached 100 lb. per capita per annum if conditions were normal.

In the period 1904-13 the average yearly consumption per person in countries named was as shown in Table I.

TABLE I. PER CAPITA CONSUMPTION OF SUGAR

	Lb.		Lb.
Australia	113	Belgium	26
United Kingdom	85	Russia	14
Germany	30	United States	78
France	28		

Comparative Production

Previous to the war the United States ranked fourth in beet sugar production, today second. This is due to decreased production in Europe, as shown by Tables II and III.

TABLE II. BEET SUGAR PRODUCTION IN THE UNITED STATES

	Tons		Tons
1913-1914	726,000	1917-1918	766,000
1914-1915	724,000	1918-1919	762,000
1915-1916	872,000	1919-1920	795,000
1916-1917	824,000		

TABLE III. COMPARATIVE PRODUCTION OF BEET SUGAR

	1913-14 Tons	1919-20 Tons
Germany	2,920,000	800,000
France	877,000	165,000
Austria	1,870,000	16,000
Czechoslovakia	.....	700,000
Poland	.....	300,000
Russia	1,918,000	None
Belgium	252,000	112,000
United States	726,000	795,000

In 1913-14 Europe produced 9,827,000 tons, and 3,503,000 in 1919-20, a decrease of over 6,300,000 tons.

Before the war, Europe had about 1,250 beet sugar factories in operation, and the European countries have realized for a long time the importance of the beet sugar industry. These governments were justified in encouraging the sugar industry, as it not only meant the development of the industry proper, but also its allied industries.

Production Should Be Increased at Home

The United States has ninety-nine factories in operation, which should be increased to 500 factories to satisfy domestic consumption. Comparing with Europe, the area is about three-quarters the total. If our beet sugar industry were developed in proportion to areas, the United States would have 930 factories in operation, or ten times the present number.

About $420,000,000 is spent abroad for importing sugar to this country each year. The distribution of this sum at home means something when analyzed.

If we say that our sugar consumption is 4,000,000 tons per year, that 23 per cent is produced in the United States proper, 24 per cent from Hawaii and Porto Rico; then the remainder, 53 per cent, or 2,100,000 tons, has to be imported. If we figure this at 10c. per lb., it means that we are sending to foreign countries $420,000,000.

The mere fact that we are sending over $400,000,000 out of the country for a product which we could produce ourselves does not signify so much until we begin to analyze how this money would have been distributed among our own people had we produced this sugar ourselves.

Supposing this sugar was made from beets, containing, say, 15 per cent sugar, at twelve tons of beets per acre, while the factory would have an extraction of 83 per cent. Then for every ton of sugar we require eight tons of beets, or a total of 16,800,000 tons of beets produced on 1,400,000 acres of land. This would mean that the sugar companies would pay the farmers $168,000,000 for beets; the farmer pay his laborers for preparing the soil, planting, cultivating and harvesting his crop, $90,000,000; while the farmer would have about 4,000,000 tons of beet tops left on his land after the crop was removed, which represents valuable cattle feed after it has been properly siloed. This would feed and fatten some 2,000,000 steers for 120 days.

The factories would be paying, during a campaign of approximately 100 days, $20,000,000 for labor in the factory for producing sugar from beets, $13,000,000 for coal, $20,000,000 to the railroad company, and $47,700,000 for miscellaneous items such as coke, lime rock, bags, maintenance and repairs.

If these factories would have pulp drying plants such as all modern factories have, they would produce 840,000 tons of dried pulp, which is also valuable cattle feed and would represent a value of approximately $27,000,000. In order to produce this 840,000 tons of dried pulp, the sugar company would spend in the neighborhood of $3,000,000 worth for labor. Approximately $113,000,000 is paid out for direct labor. If we consider the turnover of this amount alone, we get figures that would astonish us.

It is the money set in circulation by the sugar companies and farmers for labor and materials that pay for harbors, highways, schools and churches, and support our universities, and make it possible to further develop our lands, railroads and allied industries.

La Belle Coke Plant

By G. P. Blackiston

BEING the first Koppers byproduct coke plant in the Pittsburgh district, excluding Youngstown, and the only modern plant of its kind in the Ohio Valley, is the distinction which belongs to the new ninety-four oven Koppers plant of the La Belle Iron Works, located on the south bank of the Ohio River, opposite the company's main plant at Steubenville, Ohio.

The new plant, which has two batteries, each of forty-seven standard Koppers 12½-ton ovens, and is planned to permit duplication, replaces beehive ovens formerly operated by the company at La Belle, Pa.

Location of the Plant

It was the original plan of the owners to build the plant on the Ohio side of the river, adjacent to the Steubenville mill and furnaces, but the West Virginia site was decided upon when it was found impossible to secure enough land contiguous to the present plant to allow room for future expansion. The choice of the West Virginia site added considerably to the cost of the plant. A great amount of extra foundation work was necessitated, and a fill of 15 to 20 ft. over the entire site was required to bring the plant to an elevation above the flood stage of the river. The ovens themselves were carried 8 ft. above the new level

BRIDGE CONNECTING COKE PLANT WITH THE STEUBENVILLE WORKS

in order to bring the stack flues above the flood stage. An excess of 900 yd. of filling material was placed on the site and more than 70,000 yd. of concrete was used in the construction of foundation. Void wall construction was used in the oven foundation, which extends to a depth of 28 ft. below the oven mat, the voids being filled with granulated slag. Piers and curtain walls were used in the foundations of all the buildings and the floors were laid on a granulated slag fill. All underground conduits were laid before the fill was made, being erected on concrete piers.

Connection Between the La Belle, Pa., and Steubenville, Ohio, Plants

To provide traffic communication between the two plants and insure an uninterrupted supply of fuel for the furnaces, it was necessary for the company to erect and maintain its own bridge across the river. This structure, which is of the cantilever type, is 1,520 ft. in over-all length, and consists of four 100-ft. girder spans, two 30-ft. anchor spans, and a main channel span 660 ft. long. It was planned and built by the American

GENERAL VIEW OF BYPRODUCT PLANT, SHOWING LOADED COAL BARGES IN HARBOR, COAL UNLOADING DOCK, COAL HANDLING AND PREPARING PLANT, OVENS AND BYPRODUCT BUILDINGS

Bridge Co., and is the first cantilever bridge ever erected without a traveler or creeper, a crane with 110-ft. boom being used in its erection throughout. The supporting piers are of reinforced concrete 120 ft. high, which were sunk to bedrock, a distance of 43 ft. below pool level, the caisson method being employed.

Coal Supply and Transportation

A unique feature of the new plant is the coal-handling system. The coal used, excepting a small percentage which is mined in the nearby West Virginia fields and brought to the plant by railroad, is transported over the Monongahela and Ohio Rivers from the Pennsylvania coal district. For this purpose barges having a capacity of 350 to 600 tons are used, the barges being towed down the river in fleets of six to ten. Harbor facilities are provided where approximately thirty loaded barges may be tied up awaiting their turn at the unloading dock, while the same number of empties can also be accommodated. A truck hopper handles the coal shipped in by rail and a storage yard of 100,000-ton capacity is provided to insure an adequate supply for use during the winter months when the river may be closed to navigation.

Unloading Coal Barges

Coal is unloaded from the barges by two Heyland & Patterson traveling gantry cranes, with 100-ft. bridge. These cranes are each mounted on four two-wheeled trucks and travel over a 20-ft. gage track,

COKE SIDE OF OVENS AND COAL GALLERIES

PUSHER SIDE OF OVENS, SHOWING COMBINED COKE PUSHER AND LEVELING MACHINE

so that they may also be used to handle coal in the stock yard. They are equipped with 3½-ton buckets, and have a hoisting speed of 500 ft. per min. The buckets are specially designed with a view to clean unloading in minimum time with minimum labor.

When unloading, the crane remains stationary on the dock, the barge being moved along the dock by an electrically operated barge shifter. Under normal conditions the coal is dropped into a small hopper located on the dock. It is then fed through the bottom of this hopper into a 30-in. conveyor belt, which in turn discharges it into the track hopper. If it is desired to stock the coal from the river, empty cars are placed over the track hopper and the coal is discharged from the conveyor into them.

Coal Storage

Loaded cars are moved by means of a cable haul to one of the several unloading pits which are located every 125 ft. along the entire length of the storage yard. From these pits the coal is transferred to the storage pile by one of the gantry cranes. When it is desired to use coal from stock this operation is reversed, the crane loading the cars, which are then transferred to the track hopper and unloaded.

The unloading dock, which is 100 ft. long and has a 100-ft. fender at each end, was built by the National Contracting Co., of Cleveland, Ohio, while the coal-handling system and storage-yard system was designed and built by the Heyland & Patterson Co., of Pittsburgh, Pa.

From the track hopper, coal is carried by a short length pan conveyor to a 36-in. conveyor belt, which,

COKE WHARF AND SCREEN STATION IN BACKGROUND

driven by two 50-hp. G. E. motors, travels on a 20-deg. incline to the top of the breaker building, where it delivers the coal to the Bradford breaker. From the breaker which removes the slate and sulphur, the coal, having been reduced to 1½-in. lumps, is carried by a conveyor belt and discharged into the proper one of three mixing bins. From the mixing bins it is fed by gravity into the regulator by adjustable gates, so that any desired percentage of each grade of coal can be secured. The three mixer belts discharge into the same chute, which leads to the hammer mills, where the coal is pulverized to a fineness of 85 per cent through a ⅛-in. screen. It is then elevated by conveyor belts to the 1,800-ton storage bin located above the charging floor and between the two batteries of ovens. Rovins-Conveyor Belt Systems are employed throughout.

Electric Handling Equipment

The chutes on either side of the hammer mills are equipped with rotary feeders, which insure an even and constant feed and eliminate about 90 per cent of the dust which is so common about coal-handling plants.

BENZOL BUILDING, SHOWING WASH OIL COOLERS, CIRCULATING TANKS AND OVENS IN THE BACKGROUND

All the coal-handling equipment is individually motored and the control is interlocked in such a way that no conveyor belt or crusher can be started or operated until the machine next in progression is in operation; in this way spillage or piling up of the coal, if one machine should stop while the operator or attendant is not present, is eliminated; three-phase, 220-volt, alternating current is used throughout the coal-handling plant, which is equipped with General Electric motors throughout.

All the control boards for the various motors are housed in the control building, which is located at a sufficient distance from the main plant that the delicate electrical control instruments may not be injured or incapacitated by coal dust; a push button located near each motor enables the operator to stop and start the machine at will.

Coke Ovens

The pulverized coal from the storage bin is fed by gravity into one of the two (Morgan) charging machines. The ovens are of the standard Koppers 30-flue type, and the heating system is so arranged that gas is burned in the fifteen flues at one end of the furnace and the heated air and products of combustion pass out through the remaining fifteen flues

INTERIOR OF BENZOL BUILDING, SHOWING CRUDE AND PURE STILLS

to the flue stack, giving off heat as it goes. This arrangement is reversed every 30 min., insuring a continuous even heat at all times. This change is made automatically, the gas valves, stack dampers and draft dampers being controlled from the control house, which is situated between the two batteries of ovens. The entire operating mechanism is governed by an electric clock, no attendant being required. The machines which operate these valves and dampers are electrically driven, but a steam engine is provided for use in an emergency.

In the central building are also located a venturi gas meter for recording the gas consumed, and other devices for indicating the temperature, gas production, etc.

Coke Handling

The discharging, quenching and handling machinery is all standard Koppers equipment. The coke, after quenching and cooling, is dumped into a wide chute, from which it is fed through gates into a conveyor belt, on which it is carried to the grader, where it is graded into various sizes. Some is transported across the river to the furnaces, some sold for commercial consumption and the breeze used in the power plant.

Byproducts Plant

The byproduct gas given off at about 1,000 deg. C. is collected in a 16-in. main, through which it is drawn by two Connersville Stove Blower Co.'s steam-driven gas blowers at 128 cu.ft. displacement, driven by a 250-hp. Harrisburg Foundry & Machine Co. compound engine, and forced through water-tube coolers, where it is cooled to about 28 deg. C. The sudden cooling condenses the tar vapors; the tar is run off into a settling reservoir. Here the gas liquors which are contained in the condenser, being lighter than the tar itself, rise to the top and are drained off. The tar in this state is pumped to the nearby plant of the American Tar Product Co.

The gas, relieved of its tar contents, passes into the reheater, where it is brought to a temperature of 60 deg. C. and forced into the saturator, and the ammonia is removed as ammonium sulphate.

The byproducts plant is equipped with four water-tube coolers, tar extractor, reheater, saturator ammonia stills and draining tables and centrifugal driers for the ammonium sulphate, for which a 2,500-ton storage room is provided, three benzol scrubbers, two continuous condensing stills for benzol vapor, agitators, fractional condensing stills where the light oil is fractionated into crude benzol, crude toluol, crude light solvent naphtha, crude heavy solvent naphtha, agitators and four 8,000-gal. purification stills where the pure products are produced and two final coolers for the gas.

Pumping Equipment

Three Gould 20,000-gal. circulating pumps are employed to keep the water in circulation through the water tube coolers. A tar-loading pump of 10,000-gal. capacity and two 6,000-gal. hot drawing pumps are provided, together with two 6,000-gal. ammonia pumps, driven by 150-hp. Westinghouse motors for circulating the ammonia liquor through the stills. Six Gould wash oil circulating pumps with a capacity of 15,000 gal. per min. against a 180-ft. head are employed in connection with the benzol scrubbers. There are also two 150-hp. Westinghouse motor Gould single-stage circulating pumps with a capacity of 3,000 gal. per min.

The other pumping equipment, in addition to two air compressors which furnish compressed air for general use, includes a 250-hp. Westinghouse motor-driven gas pump which pumps the surplus gas through a 16-in. main over the bridge to the Steubenville furnace, and a 200-hp. Westinghouse motor-driven Ingersoll-Rand type 10 Imperial gas pump.

All pumping machinery is electric motor driven, but has emergency steam drive.

Power Plant

The power plant, which forms a separate unit, consists of four 400-hp. Stirling water tube boilers which are fed by two Epping Carpenter 12 x 7 x 12 boiler feed pumps. The boiler water is heated in a Cochrane feed water heater.

The boilers are equipped to burn either gas or coke breeze, but the coke breeze is generally used, being burned on a Cox chain grate with forced draft.

Electric current is supplied by the West Pennsylvania Power Co. from its Beech Bottom, W. Va., plant, being received at the plant at 22,000 volts, 60 cycle, three phase, but is stepped down to 2,200 and finally to 220 by a series of Westinghouse transformers.

Two G. E. motor generators, Type M. P. C. 6,500-200 Form L 200 amp., are used to furnish the direct current required in the plant.

Other notable features of the plant include a model laboratory, one office building, coal test building, and service building which is equipped with individual chain hangers for the clothes of the employees, showers, toilet accommodation, etc.

Mutual Releases in Settlement of Claims No Bar to Recovery of Metals

From the Supreme Court of New York comes a case arising out of cancellation of war contracts. The parties had made a settlement of a claim for damages on account of a breach of contract. The plaintiff claimed that the terms of settlement required the return to it of certain metals, which the defendant refused to deliver on the ground that a general release delivered to him along with plaintiff's check for $8,500 "in full settlement" concluded the entire transaction. (R. A. Union Metallic Cartridge Co. vs. Atkinson, 177 N. Y., 723.)

It appears that plaintiff had taken a contract from the French Government and part of the order was re-contracted for with the defendant. The French Government cancelled its contract with the plaintiff, which in turn cancelled its own contract with the defendant after part of the supplies had been made and delivered to plaintiff. Defendant thereupon presented his bill for damages, in three items: First, prospective profit; second, metals on hand; third, depreciation on other metals used by defendant outside the contract. Controversy arose over the claim for prospective profits. Plaintiff offered to settle this if it be reduced one-half. Reaching no agreement, suit was instituted by the defendant. During progress of this suit terms of settlement were discussed. Finally defendant's counsel offered to throw off $1,000 from the profits item, and the plaintiff's counsel replied, offering to pay $8,500 in full settlement.

The court here said that had the defendant's acceptance of this offer been unqualified, there was no doubt that he would have been obligated to return the metals, for their delivery was unquestionably contemplated in all previous negotiations. But instead of an unqualified acceptance of plaintiff's offer, defendant's counsel added, "if mutual general releases can be exchanged at the same time." This modification was accepted, the $8,500 paid and the general releases exchanged. When a few days later plaintiff asked for the return of the metals, defendant's attorney ruled that the release of the defendant given by plaintiff barred its claim. Then this suit was started by the plaintiff to recover the value of the metals.

That the offer of $8,500 was conditional upon the return of the metals—an item of $3,927.09 in the invoice claiming the damages—is unquestionable, said the court. In the light of the invoice as presented and of the protracted controversy concerning its principal items of prospective profits, throughout all of which the return of the unused metals to the plaintiff was an understood condition, to be performed as soon as the amount of the invoice should be agreed upon and paid, what is the reasonable construction to be placed on the acceptance of the offer of $8,500 in full settlement "if mutual general releases can be exchanged at the same time" became the point to be determined by the court. Did the additional clause have the same force and effect as if it had read, "Your offer is accepted on condition that the metals are not to be returned"? That is impliedly the stand taken by the defendant. But the court thought otherwise. "I think not," said the court, "whether the question is viewed as one either of fact or of law."

"There is no such magic in the condition that releases be exchanged as can obliterate all that had gone before. . . . The obligation to return the metals grew out of that transaction, was a part of it, and the release from the plaintiff to the defendant did not bar it. It was, indeed, a part of the consideration for the release."

Plaintiff, being held entitled to the metals in defendant's hands, was held entitled to their market value on the date of the demand for their delivery, with interest.

Compliance With Statute Requiring License for Sale of Fertilizer

In an action of assumpsit to recover on a note given for the price of fertilizer sold to defendant, he defended on the ground of illegal consideration for the note, in that it was given in payment of fertilizer to parties who, at the time of sale, did not have a state license authorizing them to make a sale as required by law. These parties testified they were a partnership having a contract with the Dothan Chemical Co., otherwise known as the Alabama Chemical Co., both companies being one and the same and under the same management. Under the contract the fertilizer was shipped on consignment to the partnership as trustee for the company, the property remaining in the company until sold and paid for, and when sold all proceeds, including cash, notes, open accounts, mortgages, securities therefor, etc., were to be kept separate and held by the partnership as trustee for the company, and turned over as collateral security and pledge against the notes of the partnership until their indebtedness under the contract of sale was paid in full. (Bowdoin vs. Alabama Chemical Co., 79 So., 4.)

The two questions presented for decision were: First, whether a contract of sale of commercial fertilizer made without the seller's first having taken out a license as required by the statute is void; and second, if it be void, did the sales contract in this case between the partnership and the Dothan Chemical Co. create the relation of principal and agent as regards the sale of the fertilizer in question?

Said the Alabama Supreme Court: The rule in this state is that, if a statute was not designed to prohibit the making of contracts without previous compliance with statutory provisions, but was intended merely to provide revenue, it is not void if no specific prohibition or penalty is provided or imposed. If the conditions of the statute were made for the benefit of the public, and not for the purpose of raising revenue only, an agreement is void that does not comply with the statutory conditions.

In the adoption of the statutes in question the legislative intent and primary purpose was to protect the public against being sold worthless or deleterious compounds represented as commercial fertilizers, and not merely to raise revenue, so held the court.

Referring to the second question, the court held that the contract and testimony of the partner showed the partnership was selling as agent of the chemical company, and therefore the statutes were complied with on proof that the chemical company was issued a fertilizer license by the Commissioner of Agriculture covering the period for which the sales were claimed illegally made. The contract between the partnership and the chemical company being interpreted as one of agency instead of sale, the sale to defendant for which the note was given was held to be valid, having been made under the license held by the chemical company.

A New Aluminous Abrasive

By Otis Hutchins

FOR some time the mechanical industry has needed an abrasive which could be bonded into a wheel having extraordinary sharpness, fast, cool-cutting ability, uniformity and long life—a wheel that would not only have these qualities but at the same time would be what might be termed open and "brittle" so far as its structure was concerned. Such a combination of virtues was extremely necessary in the wheels that are principally used in the grinding of high-speed and case-hardened steel and for surface grinding.

After a period of research the Carborundum Co. has perfected a new abrasive material having such characteristics. This new abrasive material is to be known as Aloxite "AA," and is now being made in quantity.

The bulk of the aluminous abrasive now used in grinding operations contains from 92 to 96 per cent alumina, 2½ to 4 per cent titanium oxide, ½ to 1 per cent each of iron oxide and silica and lesser amounts of lime and magnesia. Most of the alumina is present in the crystallized state, while the other impurities combined with a small portion of the alumina form a glass which functions as a matrix of cement holding together the crystals of alumina. The shape and size of these alumina crystals and the amount of matrix present have an important bearing upon the characteristics of the abrasive, and a microscopic study of the internal structure of the abrasive is of great importance.

Fig. 1 is a microphotograph at 8 diameters of an aluminous abrasive of the ordinary type containing about 94 per cent of alumina. The white areas represent crystals of alumina, while the black patches surrounding the white areas represent the matrix holding together the crystals. Fig. 2 is a microphotograph of an aluminous abrasive of the ordinary type containing about 96 per cent alumina, taken by means of polarized light to better bring out the size and shape of the crystals. The average diameter of the alumina crystals is about 0.7 mm. (0.0027 in.). The types of abrasive represented by Figs. 1 and 2 are admirably suited for general grinding and are used in large quantities.

Fig. 3 is a microphotograph taken with polarized light of a thin section of Aloxite "AA." The areas of the same color in the photograph represent the same allotriomorphic crystal of very large size, in some cases having a length of 12 mm. (0.5 in.) or more. Impurities are present to about 1.5 per cent or very much less than in the ordinary type of aluminous abrasive. This decreased amount of impurity has an important bearing on the characteristics of the abrasive grain and the wheel made from it. Its cutting power is increased due to the greater amount of crystallized alumina present. There is less fluxing between the bond and the grain, this resulting in the brittle wheel so necessary for rapid cutting. It also makes possible, due to the high purity of the grain, to produce wheels of very soft grade. The small amount of impurities allowed to remain in the abrasive is not objectionable, but on the other hand is extremely beneficial. It prevents the formation of skeletal crystals and prevents the more or less open and porous structure which is obtained when molten pure alumina is allowed to solidify. The resulting abrasive consequently exhibits a greater toughness and the wheel has a longer life.

The large size of the alumina crystals in Aloxite "AA" has an important bearing on the cutting power of the abrasive. As the grits commonly used are 20 and finer, almost every individual grit will consist of a fragment broken from a larger crystal of alumina and due to this fact will possess exceptional sharpness. During the process of grinding there is a breaking down of the abrasive grains in a wheel and the character of the new grains formed depends largely upon the size of the alumina crystals in the original abrasive. When the alumina crystals in the abrasive are small, a rupture of the grain may mean a tearing away of a few small crystals without fracture. However, when the crystals are large and a rupture occurs in an abrasive grain, it means that a crystal of alumina has been actually fractured and that new sharp cutting points and edges have been produced.

A New Type of Manufactured Fuel

A new type of fuel for which remarkable claims are made has been invented by Richard Bowen, managing director of Laminated Coal (Ltd.) The new fuel is produced from coal slack and dust, lignite, peat, or other material, with a binder of pitch.

Put briefly, the inventor's claim is that out of what has so far been regarded as waste material reconstructed coal, in layers or laminations, just as it occurs in the earth, has been produced.

Dust-Conveying Equipment

In the development of machinery and apparatus for the conveying of dust by suction, the Dust Recovering & Conveying Co. of Cleveland, Ohio, has arrived at the production of systems capable of handling material as coarse as ½-in gravel and ⅜-in. iron rivets from cars to bins and about the plant. There are over thirty installations in successful operation at present.

It is possible to empty a box car of bulk cement, ground limestone, raw rock phosphate or similar material at the rate of 8 to 10 tons per hour by simply guiding an intake nozzle through the material.

At first thought it would seem that this method would cause a heavy abrasive action as the materials are carried through the conduits, but it is found in practice that the bulk of the load travels in the center and away from the walls. This, however, is accounted for by the fact that the air travels swiftest in the center where it is not retarded by friction with sides and the conveyed substances follow the path of this current.

A typical installation is shown in the accompanying figure and is located at the plant of the Aluminum Co. of America, East St. Louis, Ill. The material is drawn from cars either through the lower system to dissolving tanks or by the upper and independent system to an overhead screw conveyor to storage.

Each system consists essentially of a receiving station, filter and hopper over discharge outlet; steel pipe lines from station to vacuum pump, and between station and suction nozzles, valve connections in these lines; vacuum pumps; and intake nozzles with armored hose connection.

The filter removes the material from the air and it arrives at the vacuum pump, cleansed from all dust. This permits the use of a standard motor-driven pump.

Other plants installed are handling coke and butt dust, graphite materials, smelter fume, coal dust, bauxite, phosphates, cement products, etc. The adaptation to unloading of many obnoxious materials in chemical works should be especially welcome.

Improved Method of Belt Joining

An unusual problem in the handling of hot cement clinkers with a temperature of 200 deg. and over was recently solved at the plant of the Standard Portland Cement Co., Leeds, Ala., in a cost-reducing manner.

The method decided upon for moving the clinker was a rubber conveyor belt, but the clinker could not be cooled sufficiently in the process previous to conveying to prevent scorching of the belt and its rapid destruction. The answer to this problem was found by running the belt at an incline of 12 deg., so that the lower pulley dipped into a trough of water, thus carrying a film of cold water upon the belt, onto which the hot clinker from the loading hopper was deposited.

At this point a new problem was encountered; namely, how to join the belt so that its full strength would be retained, and in a way which would withstand the extremes of temperature, the wear on the pulleys and the abrasion of the clinker. For this purpose Crescent belt fasteners were adopted, because they brought the belt ends tightly together in a snug joint, making it practically endless on the pulley side, so there was no opportunity for clinker ash to get into the joint and abrade the belt ends, and also because in this method of joining, no metal came in contact with the pulleys to cause wear and a permanent joint was thus assured.

In six months of operation, this conveyor has carried 61,000 tons of clinker, and the Standard Portland Cement Co. credits the saving of $300 in belt cost alone to this conveyor. The belt used was Goodyear Hy-temp, made particularly to withstand temperatures to 200 deg.

PNEUMATIC CONVEYING EQUIPMENT

Synopsis of Recent Chemical and Metallurgical Literature

Galvanizing Large Steel Parts by Hot Process.—A recent issue of *Iron Age* contains a description of the galvanizing plant of the Wellman-Seaver-Morgan Co.,[1] at Akron, Ohio, including details of the hot process and of the galvanizing kettle, which is of unusual size. The extreme dimensions of material which can be handled are: length, 19 ft. 6 in.; width, 3 ft. 4 in.; height, 7 ft.

Parts to be galvanized must first be thoroughly cleaned by the use of lye solution (to remove oil, grease, etc.) or a wire brush (for marking paint, heavy rust, etc.), followed by pickling. The pickling solution contains H_2SO_4 and water in the proportion of 1 to 15 by weight. About 75 lb. of 66 deg. H_2SO_4 is used per ton of steel. The solution is maintained at a temperature of about 100 deg. F. by means of steam coils. Considerable experience is required to determine when pickling is complete. In over-pickled articles the fibers of the metal are visible and the part will take a heavier coat when galvanized, which is liable to peel off through vibration.

After pickling, the article is washed with warm water in the rinse tank and then immersed in the muriatic acid tank, which contains acid and water in the proportion of 1 to 15 by weight. This solution is also heated. About 75 lb. of 18 deg. hydrochloric acid is required per ton of steel.

The article is now suspended over the galvanizing kettle, where it is thoroughly dried by the radiated heat. Before immersing in the molten zinc, the surface of the article is sprinkled with powdered ammonium chloride. The surface of the zinc bath is skimmed of zinc oxide and the article entered into the bath at the predetermined rate, which is about 10 ft. per min. for sheets. The zinc becomes greatly agitated at the points of immersion and the piece is not withdrawn for several moments after this agitation has ceased. During withdrawal, which is done at the same speed as immersion, the article is carefully examined for uncoated spots.

The ammonium chloride (or sal ammoniac) melts on the surface of the bath and gradually dissolves zinc oxide until it becomes an impure, sticky mass which is skimmed off and sold as "sal ammoniac skimmings" to chemical manufacturers. In galvanizing large sheets and tanks, an average of 5 lb. is used per ton of steel.

The 50-lb. pigs of zinc or spelter used analyze: Zinc, 99.77; lead, 0.19; iron, 0.04. The amount of zinc per sq.ft. of surface galavanized averages from 1 to 2 oz., depending on the texture of the metal and the time of immersion. The working temperature of the bath is about 800 deg. F. A great improvement can be made in the appearance of galvanized surfaces by adding a very little aluminum to the molten bath.

The acid tanks and the water tank have inside dimensions 19 x 4 x 7 ft. deep. The two acid tanks are of 6-in. double-keyed Oregon fir, with bolts and nuts encased in lead, while the water tank is of 3-in. Oregon fir. All joints are made with white lead. Each tank contains a 50-ft. steam coil of 1-in. lead pipe.

The galvanizing kettle (inside dimensions, 20 ft. x 3 ft. 6 in. x 7 ft. 6 in. deep) has side plates of 1¼-in. fire-box steel and end and bottom plates of 1-in. flange or boiler steel. There are ten fire chambers on each side of the kettle, five being gas fired and five coke fired. Either one of the firing systems is ample for the operation of the kettle, 2,000 lb. of byproduct coke or 40,000 cu.ft. natural gas per 24 hr. being required.

The kettle when full contains 200,000 lb. of zinc and about seven days are required to prepare the bath. In starting, the pigs are carefully piled endwise into the kettle until full and pieces of sheet iron are placed over the top to retain as much heat as possible. Heat is applied gradually, and at the end of four days the kettle is full of molten zinc. There will be quite an accumulation of zinc ashes (oxide) on the surface. These ashes sometimes contain considerable zinc which is melted out by throwing on and igniting several handfuls of resin. The zinc ashes are raked over during the burning of the resin in order to hasten the operation and are then skimmed off. The kettle is now ready for duty. While the kettle is in operation, some of the zinc forms an alloy with the iron of the kettle. Since the kettle is heated at the sides, this alloy settles to the bottom as dross which is removed from time to time and cast into pigs weighing about 125 lb.

In designing the first kettle installed at this plant, no provision was made for reinforcing the sides of the tank to counteract the hydrostatic pressure of the liquid metal. This pressure will be considerable in a long, deep kettle, since molten zinc has a specific gravity of 6.48. As a result, the kettle soon spread a distance of 13 in. in the center at the top. The sides were then reinforced by a pair of special cast iron braces, which were designed as beams with concentrated loads equal distances apart. The calculations involved are given in detail in the original paper.

Cast Iron as a Chemical Engineering Material.—At the January meeting of the Philadelphia Section of the American Chemical Society, HOWARD A. HOFFER, of the United States Cast Iron Pipe & Foundry Co., presented a paper on "The Manufacture of Cast-Iron Equipment Used in Chemical Engineering." An interesting report of this lecture will be found in the February *Catalyst*.

Cast iron is not acted upon by many of the chemicals used in industry and, consequently, it plays an important part in the equipment of a chemical manufacturing plant. In many instances, the major operations take place in cast-iron apparatus, such as nitrators, sulphonators, nitric acid retorts, caustic soda fusion kettles, crystallizers, digesters, autoclaves, etc. In general, the metal composition depends upon the temperature of the reaction taking place in the apparatus, as well as the concentration and chemical nature of the reacting substances.

Cast-iron water pipe is cited as an excellent example of the resistance of cast iron to corrosion. This use of cast iron dates back to 1664, when fifteen miles of pipe was laid by order of Louis XIV to supply the reservoirs in the park at Versailles. This pipe is still in use and in excellent condition after more than 250 years of service.

The most modern and practical method of making cast-iron pipe is in vertical dry sand mold, bell end down, without the use of chaplets, and casting with a shrinkhead so as to avoid the segregation of dross,

[1] "Galvanizing Plant Handles Large Work," A. H. Myers, *Iron Age*, vol. 105, p. 181, Jan. 15, 1920.

occluded gases or foreign material. In making pipe or castings intended for chemical processes chaplets should be eliminated when centering the core in the mold. This is necessary to avoid electrolytic corrosion, as a galvanic current would be generated because of the difference in potential of the metal in the chaplet and in the casting, the chemical solution in the casting acting as the electrolyte.

Cast-iron pipe is being widely used in chemical works for conveying acids, alkalis and other corrosive chemicals. In sulphuric acid work, it is used for carrying acid of 50 to 60 deg. Bé. and also for concentrating from 60 to 66 deg. Bé. At ordinary temperatures, acid down to 1.53 sp. gr. has very little effect upon cast iron, if excess of air is excluded. This material is not recommended for acid between 50 deg. Bé. and 8 per cent H_2SO_4. It is used, however, for weak acid solutions (1 to 3 per cent).

Iron apparatus for acid between 3 and 10 per cent is usually lead-lined, as in the case of ammonia saturators used for the manufacture of ammonium sulphate by the direct process.

In the manufacture of sulphuric acid, hot and cold SO_2 is carried in cast-iron pipes and the hot H_2SO_4 is cooled in cast-iron coils. Other uses for cast-iron pipe are: In mines, for handling acid mine waters; in acid soils; in stoker feed pipes, where the abrasion by the coal and the corrosion by the sulphur content cause rapid deterioration of rolled metal pipe; in byproduct coke plants for conveying the gases from the ovens, the coal tar and oils produced by the condensation of these gases, ammonia, and the solvents used for the extraction of benzol and toluol in the scrubbing towers.

Since many chemical processes require high temperatures, it is of interest to note that the tensile strength of soft cast iron remains practically constant from 100 to 1,000 deg. F., while the ultimate strengths of steel and wrought iron decrease rapidly beyond 450 deg. F. Reports from fire underwriters and fire engineers indicate that cast-iron columns will withstand 1,500 deg. F. without bending and still carry the super-imposed load, while steel columns fail at about 1,000 deg. F. Cast-iron retorts are extensively used in the chemical and allied industries at temperatures between 1,200 and 1,500 deg. F., although the life of the equipment is, of course, shorter than at lower temperatures.

Japanese Rubber Industry.—The Japanese rubber industry has made great strides since the outbreak of war. It is expected, says the *Japan Chronicle*, that orders for rubber goods will flow in from Europe, and, indeed, the exports of rubber tires during the present year have been enormous. A further development of the industry is looked for in the shape of a combination of large and small rubber factories. The desirability of this scheme seems now to have been accelerated by the receipt of large orders from Siberia. The *Chronicle* continues:

> The Okura firm is said to have recently received from the new Siberian Government orders for about 400,000 yen ($199,400) worth of rubber tube and 200,000 yen ($99,700) worth of rubber sheet. The company has now given these orders to the Mitado, the Toyo, the Nippon, and the Meiji rubber companies, which are regarded as the best rubber works in Japan, apart from foreign enterprises established here, the Okuragumi guaranteeing payment. In this connection it is said that these have decided to fill the Russian orders in co-operation with one another, so as to avoid unnecessary competition—or so as to be able to compete with a Kobe company. Their co-operation is said to extend as far as exchange of stocks and of orders for the purpose of securing efficiency and economy.
>
> This co-operation is said to portend amalgamation at an early date, so as to put the rubber industry in Japan on a firm foundation. They are also expected to extend their combination to other factories after this first step.

Recent Chemical and Metallurgical Patents

British Patents

Complete specifications of any British patents may be obtained by remitting 25c. each to the Superintendent British Patent office, Southampton Buildings, Chancery Lane, London, England.

Purifying Saccharine Liquids.—Sugar liquids are decolorized and freed from mineral substances by means of alumina or magnesia or analogous substances occurring naturally, such as bauxite or magnesite. The material, mixed with carbon or carbonaceous matter, is ignited and granulated. The liquor to be treated is filtered through the material or may be agitated with it and filtered through a filterpress. Aluminum nitrate or chloride, or calcium or sodium phosphate may be added to the liquor before treatment. (Br. Pat. 134,607—1919. J. J. Hood, London; J. Clark, Hutton, and P. G. Clark, London. Jan. 7, 1920.)

Plastic Composition.—Ground vegetable ivory is mixed with casein, lime and water and, optionally, sodium silicate, and the product is fused for making buttons, etc. An example of proportions is 12 parts ground vegetable ivory, 3 parts casein, 2 parts lime, ½ part sodium silicate. (Br. Pat. 134,619—1919. G. C. Devonshire, London, and E. T. Ford, Birmingham. Jan. 7, 1920.)

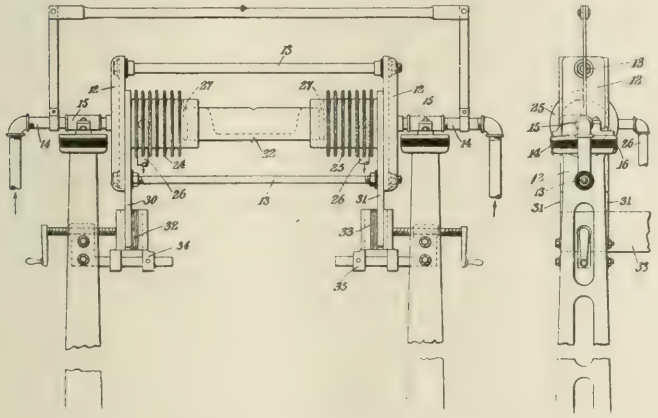
Cracking Hydrocarbons.—In cracking hydrocarbons and more particularly in converting tar oil into benzol and mineral oil into benzine, by passing a mixture of hydrocarbon vapors and steam over a heated carbonaceous material such as coke, the operation is effected in a zone of high temperature with zones of lower temperature on either side. The apparatus consists of vertical or inclined retorts through which the vapor mixture is passed upward. The central zone is heated to 500-1,200 deg. C. and the top and bottom of the retorts are kept at about 300 deg. C. The central zone extends about one-sixth to one-half of the total length of the retort, and the total height of the packing to between one-half and three-quarters of the total length. The low temperature zones may be packed with porcelain, etc. The temperature at the bottom of the retort is maintained by pre-heating the vapor mixture, and the temperature and extent of the central zone are regulated by manipulating dampers in the flues. Carbolic and creosote oils require a shorter high-temperature zone and a smaller admixture of steam than anthracene oil. The proportion of oil to water varies between 1 : 2 and 2 : 1 by volume. (Br. Pat. 135,197—1919. Naamlooze Vennootschap Nederlandsche Lichte Olie Maatschappij, Amsterdam. Jan. 21, 1920.)

American Patents

Complete specifications of any of the United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

High-Phosphorus Pig Iron From Glauconite.—THOMAS C. MEADOWS, of New York City, patents the process of charging a blast furnace with a suitable mixture of iron-potassium minerals (such as glauconite) with an iron-bearing phosphate rock, together with fluxes such as iron ore, lime rock, or silica sand, according to the exigencies of the case. As a result he procures a high-phosphorus pig iron and volatile products rich in potash. Potassium-carbon-nitrogen compounds might be recovered if drawn from the furnace near the focus before they have been broken up by reducing the descending charge. (1,322,038; Nov. 18, 1919.)

Electric Furnace.—A compact and easily operated tilting electric furnace of the resistance type has been designed by WILLIAM H. BRISTOL and M. J. JOHNSON; the features of interest are shown in the figure. The furnace is supported on pedestals and can be rotated on trunnions resting in insulated bearing 15. Water-cooled electrodes 24 and 25 are attached to the end plates 12, which are spaced by the distance rods 13. The electrodes are cooled by water which flows in through pipes 14 and out through pipes 26. One particular feature of the furnace is the method of



making contact between the carbon resistor 22 and the electrodes 24 and 25. The resistor is slipped into place through the open top of the electrodes and contact is made by inserting a graphite plate 27 between the face of the electrodes and the resistor. This effectively reduces the arcing which is usual in furnaces of this type. Another feature is the method of carrying the current from the busbars to the electrodes. Conducting plates 30 and 31 attached to the electrode are so arranged that they may be clamped by means of the clamps 34 and 35 to the conductor bars 32 and 33. This does away with the use of flexible cables. The resistor is enclosed in heat-insulating material not shown in the illustration. (1,323,576, Dec. 2, 1919; assigned to the Bristol Co. of Waterbury, Conn.)

Purification of Crude Anthraquinone.—Crude anthraquinone, produced by the oxidation of anthracene, is a mixture of the following compounds:

	Melting Point Deg. C.	Boiling Point Deg. C.
Anthracene	213	351
Anthraquinone	285	382
Phenanthrene	99	340
Phenanthraquinone	198	360
Methyl anthracene	190	360
Methyl anthraquinone	170	+360

These may be separated by a process described by CHESTER E. ANDREWS, of Pittsburgh, Pa. The crude material is heated in a current of air or other inert gas to a temperature of about 300 deg. C. The substance having the lowest boiling point will tend to vaporize first. The vapors are carried to a condensing chamber consisting of a number of compartments of successively increasing height, separated by screens of wire gauze. The process of separation is completed in these chambers by fractional condensation. By means of suspended weights, accumulations of sublimate may be jarred loose from the screens. (1,324,716; assigned to the Selden Co.; Dec. 9, 1919.)

Treatment of Anthracene Press-Cake.—The process of fractional vaporization and condensation described in U. S. P. 1,324,716 granted to CHESTER E. ANDREWS, of Pittsburgh, Pa., is also used by the inventor for the treatment of crude anthracene press-cake containing 60 to 70 per cent of impurities which consist principally of phenanthrene, methyl anthracene and carbazol. The press-cake is first treated with sufficient sodium hydroxide solution to convert the carbazol into its sodium salt. The mass is then heated to 250 deg. C. in a current of air. The vapors condense in the following order: Anthracene, methyl anthracene, phenanthrene. The residue (the sodium salt of carbazol) is dissolved in water, filtered, recrystallized, and acidified to precipitate carbazol in a relatively pure state. (1,324,717; assigned to the Selden Co.; Dec. 9, 1919.)

Nitrogen-Hydrogen Mixture.—For the production of ammonia by catalysis, the nitrogen-hydrogen mixture should be as free as possible from O_2, H_2O, sulphur compounds and CO_2, but for some catalysts small amounts of CO do not appear to be injurious except as diluents. Such a mixture may be prepared by the following method, devised by CARLETON ELLIS, of Montclair, N. J. Air and steam are blown through a gas generator fed with coal or coke low in volatile hydrocarbons. The gas obtained has the composition: Hydrogen, 15 per cent; carbon monoxide, 20 per cent; carbon dioxide, 2 per cent; nitrogen, 63 per cent; sulphur, etc., traces. After removing CO_2 and sulphur compounds by passing over lime or ferric oxide, and CO by compression, this "water-producer gas" will contain hydrogen and nitrogen in the ratio of approximately 1 : 4 by volume. This is preferably enriched, before using, by the addition of electrolytic hydrogen, in order to bring the ratio of hydrogen to nitrogen up to 1 : 3. Byproduct hydrogen from electrolytic chlorine cells may be purified by passing over platinized asbestos, whereby the oxygen and chlorine unite with the hydrogen to form water and hydrochloric acid, which may be easily removed by condensation or by passage over lime. (1,327,029; assigned to Clinton S. Lutkins; Jan. 6, 1920.)

Dyes From Halogenated Hydroxynapthoquinones.—By adding three to four parts by weight of bromine to a solution of one part by weight of juglon (5-hydroxy-α-napthoquinone) in fifteen to twenty parts of glacial acetic acid, ALVIN S. WHEELER, of Chapel Hill, N. C., obtains 2.3.8-tribrom-5-hydroxynaphthoquinone, having a melting point of about 170 deg. C. The sodium salt of this compound may be made by dissolving in ether and shaking this solution with an aqueous solution of sodium carbonate. The salt, which separates out as a purplish deposit, is soluble in water, and dyes silk and wool directly. The sodium salt of dichlorjuglon has similar properties as a dyestuff. (1,327,260; Jan. 6, 1920.)

Sodium Carbonate From Alkaline Brines.—Theoretically, in the treatment of Searles Lake brine for the recovery of alkali by precipitating sodium bicarbonate, the subsequent conversion of the latter salt into sodium carbonate should liberate enough CO_2 to precipitate an equivalent amount of bicarbonate. Losses of CO_2 are, however, unavoidable. NATHANIEL T. BACON of Peace Dale, R. I., suggests that the precipitation be started with flue gas, the purer CO_2 being reserved for final treatment. (1,330,573; assigned to the Solvay Process Co.; Feb. 10, 1920.)

Book Reviews

QUANTITATIVE ANALYSIS. By *Edward G. Mahin, Ph.D.*, professor of analytical chemistry in Purdue University. 2nd edition, revised and enlarged. 605 pp. 122 figs. New York: McGraw-Hill Book Co., Inc. Price, $3.50.

The scope of this work is so complete as to cover practically all the phases of quantitative work required of a student in a thorough modern course in chemistry. In the present edition, methods have been revised in accordance with the latest standardized procedures and new methods have been included. The treatment of each subject is exceptionally clear and there is complete freedom from any tendency toward "cook-book" style. The theory of each procedure is discussed fully, using the principles of physical chemistry wherever applicable, so that the analyst is enabled to approach a problem with a full appreciation of the limitations of the method, the possibilities of error and methods of avoiding the latter.

For the benefit of those who are unfamiliar with the earlier edition of Prof. Mahin's work, the following summary of the topics treated may be of interest:

The main divisions of the book are two—general quantitative analysis and analysis of industrial products and raw materials. A short introductory chapter on general principles is followed by a seventy-one page discussion of the methods and apparatus used in gravimetric analysis. The experiments in the next chapter include, in addition to the usual determinations, the separation of chlorine, bromine and iodine by selective oxidation. Chapter IV is devoted to the theory and practice of electro-analysis, including the use of the mercury cathode. The next three chapters cover the manipulations of volumetric analysis, the theory of indicators and the preparation of standard solutions, and prepare the student for the experiments. Chapter X takes up the important subject of oxidation and reduction in relation to volumetric analysis. Part I concludes with a discussion of titrations involving the formation of precipitates.

Rock analysis is considered first in Part II, followed by chapters on fuels (coal and gas analysis), oils, fats and waxes (burning oils, lubricating oils, edible fats and oils), and water analysis from the industrial and sanitary standpoints. Chapter XV treats the chemical and metallographical analysis of iron, plain steel and alloy steels and the chemical analysis of brass, bronze and bearing metals. The following chapter on agricultural materials covers fertilizers, milk, cream, condensed milk, butter and butter substitutes. A section on the fire assay of gold and silver ores completes the text. Four place tables of logarithms and antilogarithms, and a good index add to the usefulness of the volume.

ALAN G. WIKOFF.

Obituary

Dr. J. J. ELBERT, a technologist with the American Cyanamid Co., died suddenly at his home in Tuckahoe, N. Y., on Feb. 27. He was a graduate in chemical engineering of the Massachusetts Institute of Technology and of the University of Berlin. Dr. Elbert, after returning from abroad, was general manager of the Fibre Finishing Co., Worcester, Mass. He then associated himself with the General Chemical Co., being located in its Laurel Hill laboratories for nearly a year and later transferred to the Delaware works at Marcus Hook, Pa. For the past four years he was with the American Cyanamid Co., first as technologist, later as superintendent of the Warners plant. When the Muscle Shoals plant was ready for operation, Dr. Elbert was made assistant superintendent in charge of ammonia production, nitric acid and ammonium nitrate divisions. With the closing down of that plant, he returned to New York, where he again entered the technical department of the American Cyanamid Co. He was a member of the American Electrochemical Society and the American Chemical Society.

FRANKLIN MURPHY, former Governor of New Jersey and head of the Murphy Varnish Co., passed away Feb. 24, after an operation.

Personal

Dr. LEO H. BAEKELAND is traveling through South America in the interests of the establishment of closer relations between North and South American universities. He expects to be back in this country late in April or early in May.

R. E. COLLUM, petroleum technologist of the U. S. Bureau of Mines, has changed his headquarters from San Francisco to Dallas, Tex., where he will be in charge of the Bureau's office.

ARTHUR L. DAY, formerly the director of the Geophysical Laboratory, Washington, has announced that he will sever his connection with the Corning Glass Co. on April 1 and resume active direction of the work of the Geophysical Laboratory. GEORGE W. MOREY of the same institution is expected to return to Washington to resume his research work there about the first of May. During and since the war period he has been with the Spencer Lens Co. in its optical glass work.

DAVID F. GOULD, formerly assistant chemist in the research laboratory of the Mexican Petroleum Corporation, Destrahan, La., is now research chemist with the chemical department of The Barrett Co., Frankford, Pa.

HERMAN A. HOLZ, president of Holz & Co., Inc., New York, manufacturer of metallurgical testing and research apparatus, recently left for an extended trip through Europe to study the latest European developments in metal-testing methods and in the design of testing equipment.

N. L. BOWEN will sever his connection with Queen's University, Kingston, Ont., at the end of the present college year, to take up his former position at the Geophysical Laboratory, Washington.

R. E. HALL has resigned from the Geophysical Laboratory to accept a position with the Firestone Tire & Rubber Co., Akron, Ohio.

Dr. P. E. LANDOLT, of the Research Corporation, New York, delivered a lecture on "The Cottrell Electrical Precipitation Process" Saturday evening, March 20.

Dr. HORACE C. PORTER, formerly of the Bureau of Mines, later chemical engineer with the Koppers Co., Pittsburgh, and since the close of the war associated with the Chemical Service Laboratories, Inc., of West Conshohocken, Pa., has established an office and laboratory at 1833 Chestnut St., Philadelphia, for consulting work on fuels. Dr. Porter will make a specialty of carbonization, coking, gas and byproducts, valuation of coals, fusibility of ash, and fuel research.

E. GYBBON SPILSBURY has returned from Brazil, where he has spent the last few months in exhaustive examination of the iron and manganese resources and possibilities of utilizing native coal for their reduction.

ARTHUR L. WALKER, professor of metallurgy, Columbia University, is delivering a course of lectures on non-ferrous metallurgy before classes of the new engineering school at Harvard University. The first lecture was delivered the middle of February.

Current Market Reports

The Non-Ferrous Metal Market

New York, March 22, 1920.—The market remains quiet. Copper dropped off ¼c. in the last week, but strong inquiries developed. Tin declined sharply, from 63c. to 61½c. for spot.

	Cents per Lb.
Copper, electrolytic	18.50
Aluminum, 98 to 99 per cent	31@32
Antimony, wholesale lots	11.00
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	61.50
Lead, New York, spot	9.00
Lead, E. St. Louis, spot	8.87½
Zinc, spot, New York	8.70
Zinc, spot, E. St. Louis	8.37½

OTHER METALS

Silver	oz.	$1.21
Cadmium	lb.	1.50
Cobalt	lb.	1.50
Magnesium (f. o. b. Niagara Falls)	lb.	1.60
Platinum	oz.	150.00
Iridium	oz.	250.00
Palladium	oz.	150.00
Mercury	75 lb.	93.00

FINISHED METAL PRODUCTS	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	27.50
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	33.50
Seamless bronze tubing	34.50
Seamless brass tubing	32.00

SCRAP METALS	Cents per Lb. Buying Price
Aluminum, cast scrap	22½@23½
Aluminum, sheet scrap	22 @22¾
Aluminum clippings	25½@26½
Copper, heavy machinery comp	15 @15¼
Copper, heavy and wire	13¾@14¼
Copper, light and bottoms	12 @12½
Copper, heavy cut and crucible	15 @15½
Brass, heavy	7 @7¼
Brass, casting	10 @10¼
Brass, light	5¾@6¼
No. 1 clean brass turnings	7¾@7¾
No. 1 comp. turnings	11¼@11½
Lead, tea	5¼@5¼
Lead, heavy	7 @7½
Zinc, scrap	4¼@4½

The Iron and Steel Market

Pittsburgh, Pa., March 19, 1920.

The trade has given considerable attention to the steel ingot production report for February, made public a trifle over a week ago and referred to in last report. It may be recalled that the report indicated that steel ingots were produced during February at the rate of 44,200,000 gross tons per annum.

It is somewhat like the case of a single equation with one known quantity and two variables. The steel actually was produced, but reports during February were that mills were operating at far below capacity, say at not over 80 per cent on an average, while the most acceptable estimate of capacity, as mentioned in this report a week ago, was about 50,000,000 tons. Thus the actual production was 88 per cent of the estimated capacity, but if production were only 80 per cent of capacity the capacity would be 55,000,000 tons. The common opinion in the trade is that there was no great exaggeration of the curtailment in output occasioned by the weather, by the poor transportation service and by some minor contributing causes, but that rather the capacity is going to be found greater, on the test that favorable manufacturing conditions will eventually permit, than has been estimated on the basis hitherto used, that of taking 1916 production as the average capacity for that year and allowing conservatively for the new construction.

The argument furnishes another illustration of the errors that may be fostered by trying to interpret isolated facts into terms of steel market conditions and prospects. For steel mills to be operating at far below capacity in February constituted an augury that steel would be scarce, while for capacity to be found materially greater than had been assumed constitutes an augury that steel will be in better supply as the temporary barriers to full production disappear. That they will disappear is, of course, obvious.

Steel Scarcity Less Widespread

In the past week many indications have developed of the steel scarcity being less widespread than formerly. Not a few manufacturing consumers find themselves well supplied now, through the combined influence of mill productions being larger, mill accumulations being reduced as car supplies improved, and the time in which steel is in transit being reduced. There had been many cases of steel being two or three times as long in transit as the normal experience. At the present time receipts are therefore greater than shipments.

The pressure for prompt deliveries of steel has sensibly decreased of late. Stocks for sale are practically nil, and there is little unsold steel for delivery between now and July 1, yet there is a perceptible softening in prompt delivery prices in general. From the relatively new viewpoint, that there is no real "runaway market" in steel prices but that prompt delivery prices simply contain a delivery premium over basis prices for late deliveries, the delivery premiums are declining. The only noteworthy actual decline is in sheets, which in the past ten days have not commanded over 8c. in actual mill sales, for early shipment, while in the last week of February there had been a number of sales, of relatively small lots of course, at 10c. basis. The Industrial Board schedule, whose anniversary is about here, set sheets at 4.35c., and that price not only has been adhered to by the Steel Corporation but will, in all probability, be announced April 15 or shortly afterward as the corporation's price for second half deliveries to manufacturing consumers and third quarter deliveries to jobbers. The prices mentioned refer to common black, 28 gage, but the fancy priced sales of late have not been of common black but of special finish sheets, chiefly for the automobile trade, at the base prices mentioned plus regular extras for finish.

Prices on Bars, Shapes and Plates

Mention has been made in these reports of the likelihood that some large independents would soon open their order books on bars, shapes and plates for third quarter deliveries to regular customers at not over 3c., 3.10c. and 3.25c. respectively. It is now well assured that the prices will not be higher than just mentioned, and they may be somewhat lower, particularly to large customers. Thus the forward delivery market of the independents is not advancing, though it remains at well above the Steel Corporation level, bars and shapes as just quoted being $13 a ton and plates $12 a ton above the Industrial Board schedule, effective March 21, 1919.

The Steel Corporation shows no disposition whatever to advance its prices, and thus eventually, unless fundamental conditions on which the policy is based change, the independent prices will come down to the corporation level. That will not be for some time to come, as delivery premiums, involving really early deliveries, must first greatly decline if not disappear entirely, and such a decline has only started.

Pig Iron

The pig-iron market presents interesting possibilities. Most of the information available as to this district indicates that the market is soft, with prospects that interesting inquiries would bring out lower quotations. There is no delivery premium, an unprecedented condition when there is a high market. Some Eastern steel works are offering basic iron as far west as Pittsburgh, and a large valley interest, which used to buy pig iron when operating full, expects this time to have a surplus for sale instead.

On the other hand, reports from the Philadelphia and Buffalo markets are of tight conditions and a visible scarcity of iron. It is between buying movements in Pittsburgh and at such times the market prospects are frequently not clearly defined. The advance which sent pig iron from $18 in August, 1916, to over $50 in the following July began with sales in a dull market at cut prices. The present local

market appears to be quotable, as for the past two or three weeks, at $42 for bessemer, $41.50 for basic and $42 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.40, but should important business develop these quotations might be found to have been largely nominal.

Steel

There is not much inquiry for billets, but considerable tonnages could probably be sold if early deliveries could be offered. For both billets and slabs the market for prompt shipment seems to be $65 to $70, with small billets at perhaps $10 more. The especially fancy priced sales of sheet bars, at $90 and thereabout, appear to have ceased, the market being quotable generally at $70@$80, depending on the standing of the buyer. One interest has covered regular customers for second quarter at $60, but that is not a market price, representing a sort of compromise in consideration of the fact that the Steel Corporation is still taking care of its customers as far as it can at the old Industrial Board price of $42.

Ferro-Alloys

Producers have advanced ferromanganese, formerly $160, to $180 as minimum, some quotations of $200 being out. These prices are for second half, delivered, 78 to 80 per cent. Earlier deliveries run up to $225 or higher, but involve only very small lots. English is out of the market, there being no fresh quotations, though with such high domestic prices English is likely to become a factor again. Electrolytic ferrosilicon is $80@$81, delivered, for 50 per cent and $140 for 75 per cent. Bessemer ferrosilicon is $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, f.o.b. furnaces at Jackson and New Straitsville, Ohio.

Chemical and Allied Industrial Markets

New York, March 20, 1920.

General conditions remain practically unchanged, with the spot market a little tighter if anything. Any price movement recorded has been upward, especially in the alkali group. Under the influence of the more favorable rate of exchange foreign inquiry has picked up slightly.

General Chemicals

Ethyl alcohol has advanced again and the present low mark is $5.25 per gal., with difficulty in obtaining any material even at this price. In sympathy with ethyl grade, *methyl* has also advanced, the nominal quotation for 95 per cent being $2.25, while actual sales are reported as high as $3.50, and prices as high as $5 have been received for 97 per cent pure. *Denatured* has been advanced 20c. a gal., present quotations reading $1 for 188 and 96c. for 190 proof. This advance was brought about by the loss of two tank steamers of molasses, belonging to a controlling factor in this market, from which several million gallons of alcohol were to be obtained. *Methyl* alcohol is on the advance due to unfavorable labor conditions among the unskilled labor of the South, but it is the opinion of one large factor in the market that this condition will be easier around the beginning of May. *Sodium nitrite* fell back and although there is very little material on the spot market contract prices are going back to normal. Spot prices range from 50c.@60c. per lb. *Sodium bichromate* holds firm at 33c.@35c. per lb., some small supplies on the spot market going at a slightly higher price. *Oxalic crystals*, under pressure of heavy demand, advanced 3c. per lb., the present quotation being 43c.@48c. per lb. for spot and 35c@42c. for carlots on contract. *Barium chloride* is slightly easier, $140@$150 being the spot price and $125@$135 per ton for contracts. It is reported that one large producer who has been out of this market for some time past has come back, and with larger supplies the present scale of prices should be broken.

It is reported that producers are completely sold out on *acetic acid*, glacial, 99½ per cent. The spot market is somewhat tighter with $15@$15.50 per cwt. the best quotation. This condition will continue till the end of the summer, by which time it is hoped manufacturers will be caught up on their contracts. *Sal soda* holds firm at $1.25@$1.35 per cwt. for carlots and $1.40@$1.50 on spot. Buying on spot market increased during the past week, which forced material in second hands up slightly. *Sodium borate* holds firm on contract price at 8½c.@8¾c. per lb., while the spot market advanced to 9c.@9½c. *Formaldehyde* is still at a premium on the spot market, being listed at 90c.@$1 per lb. The nominal market price of 38c.@40c. still solds, but there is no material to be had at these prices on contract.

Coal-Tar Products

The coal-tar products market remains in the same position in which it was last week. Very few price changes have occurred and except for further advance of spot materials there is very little to report. It is the opinion of those engaged in this industry that there is no relief in sight from the current high prices. The demand continues heavy, with very little material being offered for immediate delivery. *Salicylic acid* holds firm at 55c.@60c. per lb. for U. S. P., while the *technical* grade, under the influence of more active demand, increased to 45c.@50c. per lb. The spot market on *aniline oil* continues cramped, but prices are holding firm at 34c.@45c. per lb., while the *salts* are practically unobtainable, with a nominal quotation of 42c.@48c. per lb. All grades of *beta naphthol* are very scarce and prices ranging from 75c.@$1 per lb. are being offered. Quotations on *H acid* remain nominal, as there is practically no material available on the spot market.

Waxes

The wax market has dropped slightly during the past week due to the arrival from abroad of several shipments of beeswax and carnauba. Spot material in these two lines dropped, with 38c.@40c. per lb. being asked for natural crude yellow beeswax, while *carnauba*, No. 3, North Country, dropped to 43c.@45c. per lb.

Flotation Oils

There has been a general advance in flotation oils during the past week, caused by shortage of supplies. Manufacturers are not able to meet the demand because of the inefficiency of the laborers. *Pine oil*, steam dist., sp.gr. 0.930-0.940, is quoted at $1.65 per gal.

Naval Stores

The market continues quiet with a further drop in the *rosins*. It is reported that the difficulty the producer in the South is having with labor has caused a shortage, which, coupled with decreasing domestic demand and very inactive foreign inquiry, accounts for the present declining market. B-D grades are listed at $17.50@$18, E-I grades at $17.50@$19 and WG-WW at $22@$22.50 per 280 lb.

Turpentine is quoted higher than it ever has been before, not excepting war prices. Supplies are extremely low in Savannah and no relief is expected until the new crop arrives. The jump of 15c. during the past week places turpentine at a nominal quotation of $2.20 per gal. It is the general opinion of those engaged in the trade that the limit has not been reached but will continue upward till relief from the new crop is received.

Vegetable Oils

The oil market during the past week remains in practically the same position. *Linseed* oil, raw, carlots, is firmer at $1.84 per gal., while boiled, carlots, is bringing $1.87. *Cottonseed* holds firm at former levels with the usual fluctuations during the week but ending at the same price. *Ceylon* grade, in bbl., 18c.@19½c. per lb. and *Cochin* grade, 20½c.@23c. per lb.

Ores and Semi-Finished Products

The *tungsten* bill which has been before the Senate for consideration for some time has again been sidetracked. There has been practically no business on this item and as low as $6 has been received on *wolframite*. The *manganese* market holds firm under the pressure of demand for ferromanganese.

Sulphur, roll (brimstone)	100 lb.	3.20 –.....	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½ –.....	.46 – .50
Tin oxide	lb.	.50 – .60	.65 – ....
Zinc carbonate, precipitate	lb.	.....–.....	.20 –.....
Zinc chloride, gran	lb.	.13 –.....	13½ – .15
Zinc cyanide	lb.	.49 –.....	.50 – .60
Zinc dust	lb.	11½ – 12½	.13 – .15
Zinc oxide, U. S. P	lb.	.....–.....	.19 – .21
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 — $1.10
Alpha naphthol, refined	lb.	1.40 — 1.60
Alpha naphthylamine	lb.	.40 — .50
Aniline oil, drums extra	† lb.	.34 — .45
Aniline salts	† lb.	.42 — .48
Anthracine, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde (f.f.c.)	lb.	2.00 — 2.10
Benzidine, base	lb.	1.25 — 1.35
Benzidine, sulphate	lb	1.00 — 1.15
Benzoic acid, U.S.P	lb.	.90 — 1.10
Benzoate of soda, U.S.P	lb.	.80 — 1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 — .36
Benzol, 90%, in drums (100 lb.)	gal.	.25 — .29
Benzyl chloride, 95-97%, refined	lb	.35 — .40
Benzyl chloride, tech	lb	.25 — .35
Beta naphthol benzoate	† lb.	.50 — .65
Beta naphthol, sublimed	† lb.	.70 — .90
Beta naphthol, tech	† lb.	.45 — .55
Beta naphthylamine, sublimed	lb	2.25 — 2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 — 1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.85 — 1.00
Cresylic acid, 50%, first quality, drums	gal	.60 — .70
Dichlorbenzol	lb.	.07 — .10
Diethylaniline	lb.	1.40 — 1.50
Dimethylaniline (nominal)	lb.	.95 — 1.50
Dinitrobenzol	lb.	.26 — .37
Dinitroclorbenzol	lb.	.25 — .30
Dinitronaphthaline	lb.	.45 — .55
Dinitrophenol	lb.	.32 — .36
Dinitrotoluol	lb.	.38 — .45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 — .40
Diphenylamine (nominal)	lb.	.55 — .65
H-acid (nominal)	† lb.	1.70 — 1.80
Metaphenylenediamine	lb.	1.15 — 1.80
Monochlorbenzol	lb.	.12 — .15
Monoethylaniline	lb.	1.50 — 1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 — .08
Naphthaline, flake	lb.	.07 — .08
Naphthaline, balls	lb.	.08½ — .10
Naphthionic acid, crude	lb.	.70 — .85
Nitrobenzol	lb.	.14 — .19
Nitro-naphthaline	lb.	.30 — .35
Nitro-toluol	lb.	.20 — .30
Ortho-amidophenol	lb.	3.75 — 4.25
Ortho-dichlor-benzol	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.80 — 1.25
Ortho-nitro-toluol	lb.	.25 — .40
Ortho-toluidine	lb.	.25 — .45
Para-amidophenol, base	lb.	2.50 — 3.50
Para-amidophenol, HCl	lb.	2.50 — 3.25
Para-dichlor-benzol	lb.	.12 — .18
Paranitraniline	lb	1.00 — 1.35
Para-nitro-toluol	lb	1.35 — 1.50
Paraphenylenediamine	lb.	2.15 — 3.00
Paratoluidine	lb.	1.75 — 2.50
Phthalic anhydride	lb.	.65 — .75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 — .25
Pyridin	gal.	2.00 — 2.50
Resorcin, technical	lb.	4.25 — 4.50
Resorcin, pure	lb.	6.50 — 6.75
Salicylic acid, tech., in bbls. (110 lb.)	† lb.	.45 — .50
Salicylic acid, U. S. P.	† lb.	.55 — .60
Salol	lb	.90 — 1.00

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.22 —	$0.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow †	lb.	$0.38 —	$0.40
Beeswax, refined, yellow †	lb.	.40 —	.41
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1. (nominal)	lb.	.80 —	.88
Carnauba, No. 2, regular (nominal)	lb.	.65 —	.78
Carnauba, No. 3, North Country (nominal) †	lb.	.43 —	.45
Japan	lb.	.17 —	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	..... —	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.10½
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.08
Paraffine waxes, refined, 128-130 m.p.	lb.	.11 —	.11½
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.14
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.47
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	†280 lb.	$17.50	—$18.00
Rosin E-I	280 lb.	17.50	— 19.00
Rosin K-N	280 lb.	19.45	— 21.00
Rosin W. G.-W. W.	280 lb.	22.00	— 22.50
Wood rosin, bbl.	280 lb.	15.50	— 17.50
Spirits of turpentine	gal.	.....	— 2.20
Wood turpentine, steam dist.	gal.	.....	— 2.15
Wood turpentine, dest. dist.	gal.	.....	— 1.95
Pine tar pitch, bbl.	200 lb.	8.40	— 8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	— 15.00
Retort tar, bbl.	500 lb.	15.00	— 15.50
Rosin oil, first run	gal.	.93	— .95
Rosin oil, second run	gal.	.96	— .97
Rosin oil, third run	gal.	1.10	— 1.15
Rosin oil, fourth run	gal.	.....	— 1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.40½ —	$0.42
Upriver coarse	lb.	.30½ —	.32
Upriver caucho ball	lb.	.31 —	.32¼
Plantation—First latex crepe	lb.	.48¾ —	.50
Ribbed smoked sheets	lb.	.48½ —	.48¾
Brown crepe, thin, clean	lb.	.45 —	....
Amber crepe No. 1	lb.	.46 —	.47

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.19 —	$0.20
Castor oil, AA, in bbls.	lb.	.20 —	.23
China wood oil, in bbls.	lb.	.23¾ —	.25½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18 —	.19¼
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½ —	.23½
Corn oil, crude, in bbls.	lb.	.17 —	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½ —	.18
Cottonseed oil, summer yellow	lb.	.18½ —	.19
Cottonseed oil, winter yellow	lb.	.22 —	.24½
Linseed oil, raw, car lots	gal.	1.84 —	
Linseed oil, raw, tank cars	gal.	1.77 —	
Linseed oil, boiled, car lots	gal.	1.87 —	
Olive oil, commercial	gal.	2.50 —	3.00
Palm, Lagos	lb.	.16 —	.16½
Palm, bright red	lb.	.15½ —	.17½
Palm, Niger	lb.	.15 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.22½ —	.24
Peanut oil, refined, in bbls.	lb.	.27 —	.28
Rapeseed oil, refined, in bbls.	gal.	1.70 —	
Rapeseed oil, blown, in bbls.	gal.	1.65 —	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.18½ —	.23
Soya bean oil, tank cars, f.o.b. Pacific coast	lb.	.16¾ —	.20

FISH

Winter pressed Menhaden	gal.	$1.18 —	....
Yellow bleached Menhaden	gal.	1.22 —	....
White bleached Menhaden	gal.	1.25 —	....
Blown Menhaden	gal.	1.30 —	1.35

† (See New York market letter)

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00	—$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.04½ —	.05½
Blanc fixe, pulp	ton	30.00 —	50.00

Talc, imported	ton	60.00 —	70.00

*Nominal

Refractories

Following prices are f.o.b. works:

Chrome brick net ton	75-80 at Chester, Penn.
Chrome cement net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay 1,000	38-45 at Clearfield, Penn.
Clay brick, 2nd quality 1,000	33-35 at Clearfield, Penn.
Magnesite, dead burned net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in. net ton	80-85 at Chester, Penn.
Silica brick 1,000	45-50 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.22
Ferro-manganese, 70-80% Mn.	gross ton	170.00 —	200.00
Spiegeleisen, 16-20% Mn.	gross ton	50.00 —	70.00
Ferro-molybdenum, per lb. of Mo.	lb.	2.25 —	2.75
Ferro-silicon, 50%	gross ton	85.00 —	95.00
Ferro-silicon, 75%	gross ton	150.00 —	175.00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	.90 —	1.10
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50 —	7.50

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	.....
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	.....
Petroleum coke, refinery, Atlantic seaboard	net ton	..... —	14.00
Fluor spar, gravel, f.o.b. mines	net ton	..... —	25.00
Manganese ore, 45% Mn and over	unit	.75 —	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00 —	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00 —	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.25 —	6.75
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	.....
Rutile, 95% TiO_2	lb.	.11 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

*Government prices.

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

COLUSA—B. L. McCue, city clk., will soon receive bids for the construction of a filtration plant, etc. Estimated cost, $38,000.

EL CENTRO—Mr. Rice, city engr., has prepared plans for the construction of a series of settling basins 2 mi. from here. Bonds amounting to $150,000 will probably be voted upon to defray expenses of this project.

FOREST—The Kate Hardy Mining Co. plans to construct a crushing plant, etc. Estimated cost, $30,000.

SELMA—The town plans an election to vote on $65,000 bonds to construct outfall sewer and septic tank. E. P. Todd, city clk.

WILLIAMS—The Bd. Supervs. are preparing plans for the construction of a water system, cost, $22,000 and a sewage disposal system, cost, $18,800. The town will vote bonds for the project. A. Givan, Sacramento, engr.

WILMINGTON—The California Barium & Chemical Co. engaged A. C. Martin, archt., 430 Higgins Bldg., Los Angeles, to prepare plans for the construction of a group of factory buildings for the manufacture of dyes, chemical sugar and other products. Smelting equipment, etc., will be installed in same. Address James O. Sword, Higgins Bldg., Los Angeles.

Connecticut

NEW BRITAIN — Landers, Frary & Clark, Commercial St., plan to build a 1-story, 50x104-ft. manufacturing plant addition. Estimated cost, $25,000. Max J. Unkelbach, 162 Main St., archt.

Illinois

CHICAGO—The Alemite Die Casting & Mfg. Co., 341 West Chicago Ave., had plans prepared for the construction of its new plant on the northeast corner of Belmont and Washtenaw Aves.

CHICAGO—The Western Petroleum Refiners Association, 14 East Jackson Blvd., is having plans prepared for the construction of a pipeline from the Kansas, Oklahoma and northern Texas fields to terminate in a large refinery here. Estimated cost, $25,000,000.

Indiana

KOKOMO—The Como Chemical Co. is building a large plant for the production of aluminum salts and heavy chemicals. H. M. Gray, pres.

Iowa

MADRID—The city awarded the contract for the construction of a sewage disposal plant, to Ward & Weighton, 516-17 Davidson Bldg., Sioux City, at $38,125.

Kansas

SALINA—The city has awarded the contract for the construction of a sewage disposal plant, to Amerman & Snyder, at $18,390.

Louisiana

BATON ROUGE—The Constantin Refining Co., New 1st Natl. Bldg., Tulsa, Okla., has purchased a 600 acre site about 2½ mi. north of here and plans to build a 20,000-bbl. oil refinery on same. Estimated cost, $2,000,000.

MANSFIELD—The Hagan Producing & Refining Co. plans to build an oil refinery. Estimated cost, $1,000,000. Address John W. Hagan, Tulsa, Okla.

SHREVEPORT — The Associated Producing & Refining Co. has purchased a 37-acre site and plans to build a 1,000-bbl. oil refinery with an initial unit on same. Estimated cost, $100,000.

SHREVEPORT — The Great Southern Producing & Refining Co., 1007 Hume-Mansur St., Indianapolis, Ind., plans to build a 1,500-bbl. oil refinery near here. Estimated cost, $250,000.

Maine

PORTLAND—A. S. Hinds, West St., has awarded the contract for the construction of a 4-story laboratory on Forest Ave., to Blackstone & Smith, 185 Middle St. Estimated cost, $500,000.

Maryland

BALTIMORE—The Emery Steel Castings Co., 603 Continental Bldg. and 210 North Garrison Lane, is in the market for electric furnaces and complete equipment for a steel foundry. Louis J. Emery, genl. mgr.

DUKES (Adelina P. O.)—The West Virginia Paper & Pulp Co., 200 5th Ave., New York City, is having plans prepared for the construction of two 2-story paper-manufacturing buildings. Estimated cost, $300,000. Lockwood, Greene Co., 101 Park Ave., New York City, archts. and engrs.

Massachusetts

BOSTON—Boston College, 688 Boylston St, is having plans prepared for the construction of a 3-story science building. Chemical equipment will probably installed in same. Estimated cost, $150,000. Maginnis & Walsh, 100 Boylston St., archts.

FITCHBURG—The Fitchburg Paper Co., 804 Main St., has awarded the contract for the construction of a paper mill, to the Casper Ranger Constr. Co., 20 Bond St., Holyoke. Estimated cost, $400,000.

WEST DUDLEY—The Burmus Paper Co. has awarded the contract for the construction of a 2-story, 50x220-ft. manufacturing building, to the H. Wales Lines Co., 134 State St., Meriden, Conn. Estimated cost, $60,000.

WEST ROXBURY (Boston P. O.)—The town of Brookline, Water Dept., is having plans prepared for the construction or a 2-story, 40x40-ft. laboratory. Estimated cost, $25,000. Stricland & Law, Pemberton Sq., Boston, archts.

Michigan

KALAMAZOO — The Kalamazoo Sanitary Mfg. Co. is in the market for equipment for the manufacture of pottery for sanitary plumbing ware.

Montana

HARLEM—The city plans an election April 5 to vote on $45,000 bonds to construct a filtration plant, etc. C. P. Wells, 804 1st Natl. Bank Bldg., Great Falls, engr.

New Jersey

TRENTON — The Natl. Porcelain Co., Southard St., received bids for the construction of a 2-story, 51x72-ft. porcelain plant, from Hiram Hughes, 1145 Indiana Ave., $19,310; Trenton Bldg. Corp., 1430 Riverside Ave., $20,975; Edward A. Lee, 511 Tyler St., $21,000.

TRENTON—The Thermoid Rubber Co., Whitehead Rd., has awarded the contract for the construction of a 1-story, 150x200-ft. rubber mill to the N. A. Bugbee Co., 206 East Hanover St. Estimated cost, $75,000.

New Mexico

ESTANCIA—The town plans an election April 6 to vote on $10,000 bonds to construct an outfall sewer and septic tank. C. H. Calkins, engr.

New York

HARRISON—The Diana Paper Co. had plans prepared for the construction of a 60x94-ft. addition to present plant. Estimated cost, $10,000. Charles E. Eaton, 307 Sherman Bldg., Watertown, engr.

MARCY — The State Hospital Comn., Capitol, Albany, received bid March 17 for the construction of a mortuary, laboratory and tuberculosis hospital building at the Utica State Hospital, here, from the Peter Keeler Bldg. Co., 425 Orange St., Albany, $186,270.

MASSENA—The Massena Farmers' Cooperative Corp. has awarded the contract for the construction of additions and repairs at the Erwin factory to C. I. Allen. The company is in the market for milk-handling and laboratory equipment. Estimated cost, $15,000.

SCENECTADY—The Mica Insulator Co., Dock St., has awarded the contract for the construction of a 4-story, 50x120-ft. factory, and a 1-story addition to present building, to the Turner Constr. Co., 242 Madison Ave., New York City. Estimated cost, $125,000.

SYRACUSE—The Will & Baumer Co., Liverpool, plans to build a 3-story, 72x255-ft. candle factory on Liverpool Rd. Estimated cost, $200,000. Guy L. Noble, Union Bldg., archt. and engr.

WATERTOWN—The Taggart Bros. Co., 595-597 Main St., West, will build a 1-story, 67x200-ft. addition to paper mill plant. Estimated cost, $40,000. Work will be done by day labor.

Ohio

CLEVELAND—The city plans to construct a reservoir, filter house, etc. at Baldwin, cost, $2,000,000; and at East Side filter plant with necessary pumping equipment, including filter basin, etc., cost, $5,000,000. A. V. Ruggles, City Hall, engr.

CLEVELAND—The Cleveland Automobile Co., East 131st St., has awarded the contract for the construction of a 1-story, 80x80-ft. heat-treating plant on London Rd., to John Gill & Son, 1301 Citizens Bldg. Estimated cost, $60,000. Noted March 3.

Oklahoma

ADA—A. L. Brown plans to construct a large brick plant. Large deposits of the shale for making this product lie south of here. Estimated cost, $75,000.

Pennsylvania

NEW HOPE — The New Hope Paper Mills has awarded the contract for the construction of a 2-story, 60x144-ft. paper mill, to C. R. Randall, 43 North Hermitage Ave., Trenton, N. J. Estimated cost, $25,000.

Texas

TEXAS CITY—The White Oil Corp., 501 5th Ave., New York City, plans to build a 15,000-bbl. oil refinery on an 800-acre site recently acquired here. Estimated cost, $2,000,000.

Wisconsin

BURLINGTON—The Burlington Brass Wks. is having plans prepared for the construction of a 1-story, 100x140-ft. foundry. Edmund B. Funston, Robinson Block, Racine, archt. and engr.

SHEBOYGAN.— The Wisconsin Textile By-products Co., Calumet Rd., is having plans prepared for the construction of a 2-story, 60x87.6-ft. addition to present building and a 60x72.6-ft. building. Estimated cost, $30,000. W. C. Weeks, Ontario Ave., archt.

British Columbia

VICTORIA—The Sidney Rubber Roofing Co., Sidney, plans to construct a factory. Estimated cost, $200,000. R. W. Mayhew, mgr.

Ontario

CHATHAM—The city will vote upon bylaw appropriating $37,000 to construct a rapid sand gravity filtration plant with chlorination apparatus. F. P. Adams, City Hall, engr.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will hold a meeting on March 26, the subject of which is "Peace Uses for War Products."

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at Asbury Park, N. J., June 22 to 25.

THE AMERICAN ZINC INSTITUTE will hold its spring meeting May 10 and 11 at the Congress Hotel, Chicago, Ill.

THE CHAMBER OF COMMERCE OF THE U. S. announces that its eighth annual meeting will be held at Atlantic City, April 27 to 29, the subject of which will be "Increased Production."

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theatre: "Helium," Monday, March 29, at 4 P.M., Dr. R. B. Moore, chief chemist, U. S. Bureau of Mines (*Lantern*); "Romance of Leather Making," Tuesday, April 13, at 4 P.M., E. A. Brand (*Lantern*); "Water Supply and Drainage in War Cantonments," Wednesday, April 21, at 4 P.M., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers Process), Thursday, April 29, at 4 P.M., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 P.M., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 P.M., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE CONNECTICUT VALLEY SECTION of the American Chemical Society will hold a meeting Saturday, March 27, at the Hotel Elton, Waterbury, Conn. Prof. Joseph W. Richards, of Lehigh University, will speak on "The Principles Underlying the Electrochemical Industries." The Scoville Manufacturing Co.'s laboratory will be visited after the meeting.

THE ELECTRIC FURNACE ASSOCIATION will hold a meeting in Boston April 8 to 10, together with the American Institute of Electrical Engineers and the American Electrochemical Society. The subject is "Electrically Produced Alloys and Power for Electrochemical Purposes." Headquarters will be at the Copley-Plaza Hotel.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE INTERNATIONAL MINING CONVENTION will be held in Seattle April 7 to 10.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MINE INSPECTORS INSTITUTE OF AMERICA will hold a meeting in Cleveland, Ohio, July 13.

THE MINING SOCIETY OF NOVA SCOTIA has planned a meeting for May 4 and 5 which will be held in Glace Bay.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE PENNSYLVANIA SAFETY CONGRESS for 1920 will be held at Harrisburg, Pa., March 21 to 25 inclusive.

THE SOCIETY OF INDUSTRIAL ENGINEERS will hold its national spring convention March 24 to 26 at the Bellevue-Stratford Hotel, Philadelphia.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 14 to 16.

New Publications

GEOLOGY AND OIL POSSIBILITIES OF THE NORTHERN PART OF OVERTON COUNTY, TENN. AND OF ADJOINING PARTS OF CLAY, PICKETT AND FENTRESS COUNTIES. Bull. 24, published by the State Geological Survey, Nashville, Tenn.

BRITISH INDUSTRIAL RECONSTRUCTION AND COMMERCIAL POLICIES, by Fred W. Powell; Special Agents Series No. 193, Bureau of Foreign and Domestic Commerce, Department of Commerce, Washington, D. C.; sold by the Superintendent of Documents, Government Printing Office, Washington, D. C., 10c.

SOLID LUBRICANTS, Bull. No. 4, Department of Scientific and Industrial Research, 15 Great George St., Westminster, S. W. 1, England; price 6d net. The bulletin is a summary of existing literature and not a statement based upon actual research work.

STATE OF ILLINOIS, Department of Registration and Education, Division of the State Geological Survey, has issued Bull. No. 4, on Oil Investigations in 1917 and 1918.

INDUSTRIAL RESOURCES OF THE PHILIPPINE ISLANDS. This is a 40-page pamphlet published by the Bureau of Science, Department of the Interior of the Government of the Philippine Islands, Manila. It covers chemical technology, limestone and silicate industries, non-metallic and mineral resources, fisheries, etc.

THE MISSISSIPPI VALLEY ASSOCIATION, 10 South LaSalle St., Chicago, has issued the report of its Foreign Trading and Banking Committee in a pamphlet entitled "Foreign Trade Survey, Our Share and How to Get It." The work is submitted after four months of exhaustive research as an aid to business concerns in doing their share of the world construction program. The economic and legal aspects are presented. The Association will welcome inquiry on the subject.

FIRST ANNUAL REPORT OF THE SECRETARY OF THE STATE BUREAU OF MINES AND GEOLOGY, for the period April 20 to Dec. 31, 1919. Published by the State of Idaho, under the direction of the Bureau of Mines and Geology.

THE PRODUCTION OF COPPER, GOLD, LEAD, NICKEL, SILVER, ZINC AND OTHER METALS IN CANADA, during the calendar year 1918. Published by the Department of Mines, Ottawa.

COST REPORTS OF THE FEDERAL TRADE COMMISSION, "Copper." Published at the Government Printing Office, Washington, D. C.

BANK AND PUBLIC HOLIDAYS THROUGHOUT THE WORLD. Published by the Guaranty Trust Co., New York.

THE MINERAL INDUSTRY OF UTAH, by Robert S. Lewis and Thomas Varley; Bull. No. 12, Utah Engineering Station, Department of Metallurgical Research. Published by the University of Utah, State School of Mines, in Co-operation of the U. S. Bureau of Mines. Copies may be obtained, free of charge, by applying to the Director, State School of Mines, University of Utah, Salt Lake City, Utah.

COMBINING FOR FOREIGN TRADE. Published by the Guaranty Trust Co., New York City.

THE ENGINEERING FOUNDATION has published a progress report to the United Engineering Societies outlining the work accomplished through co-operation with the National Research Council.

BIBLIOGRAPHY SERIES, published by Arthur D. Little, Inc., Boston: No. 1, Chemical Warfare, reprinted from "Special Libraries," November, 1919; No. 2, The Production of Alcohol From Sulphite Waste Liquors, reprinted from *Paper*, Dec. 3, 1919; No. 3, Industrial Research, reprinted from "Special Libraries," January, 1920.

STRATIGRAPHY AND CORRELATION OF THE DEVONIAN OF WESTERN TENNESSEE, by Carol O. Dunbar. Bull. No. 21, published by the State Geological Survey, Nashville, Tenn.

THE NORTON CO., Worcester, Mass., has published a booklet on "Little Known Facts About Grinding." These are a series of brief articles by Howard W. Dunbar treating commonplace facts concerning grinding, and reprinted from *Grits and Grinds*, the periodical of the Norton Co.

COAL RESOURCES OF DISTRICT V (Saline and Gallatin counties), by Gilbert H. Cady. Bull. No. 19 (Co-operative Mining Series), published by the Department of Registration and Education, Division of the State Geological Survey, Urbana, Ill.

THE U. S. COUNCIL OF NATIONAL DEFENSE has published a booklet which is entitled "Readjustment and Reconstruction Information."

NEW U. S. TARIFF COMMISSION PUBLICATIONS: Tariff Information Series No. 15, Costs of Production in the Dye Industry 1918-1919; No. 13, The Acids of Paragraph 1 and Related Materials Provided for in the Tariff Act of 1913. A general economic survey of the industries producing citric, oxalic, formic, lactic, gallic, boric and tartaric acids.

NEW FEDERAL BOARD FOR VOCATIONAL EDUCATION PUBLICATIONS: Bull. No. 39, Coal-Mine Gases; Bull. No. 43, The Labor Audit, a Method of Industrial Investigation.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: I: 11, Gold, Silver, Copper, Lead, and Zinc in the Eastern States in 1918, by James M. Hill (Mineral Resources of the U. S., 1918, Part I), published Jan. 26, 1920; I: 12, Gold, Silver, Copper, Lead and Zinc in Nevada in 1918, by V. C. Heikes (Mineral Resources of the U. S., 1918, Part I), published Jan. 27, 1920; Bull. 694, Bibliography of the Metals of the Platinum Group, Platinum, Palladium, Iridium, Rhodium, Osmium, Ruthenium, 1748-1917, by James Lewis Howe and H. C. Holtz; Bull. 705, Conservation Through Engineering, by Franklin K. Lane, which is an extract from the Annual Report of the Secretary of the Interior.

NEW BUREAU OF MINES PUBLICATIONS: Miners' Circular No. 22, Dangerous and Safe Practices in Bituminous Coal Mines, by Edward Steidle; Miners' Circular No. 26, Miners' Safety and Health Almanac for 1920, compiled by R. C. Williams, published in co-operation with the United States Public Health Service; Tech. Paper 232, Absorption as Applied to Recovery of Gasoline Left in Residual Gas From Compression Plants, by W. P. Dykema and Roy O. Neal; Tech. Paper 236, Abatement of Corrosion in Central Heating Systems, by F. N. Speller; Tech. Paper 237, Safe Practice in Using Wire Ropes in Mines, by O. P. Hood and R. H. Kudlich; Tech. Paper 257, Waste and Correct Use of Natural Gas in the Home, by Samuel S. Wyer; Bull. 175, Experiment Stations in the Bureau of Mines, by Van H. Manning; Bull. 181, Abstracts of Current Decisions on Mines and Mining, by J. W. Thompson; Report of Committee on Standardization of Petroleum Specifications.

NEW BUREAU OF STANDARDS PUBLICATIONS: Circular No. 87, Recommended Specifications for Zinc Oxide, Dry and Paste; Circular No. 88, Recommended Specifications for Leaded Zinc Oxide, Dry and Paste; Scientific Paper No. 331, A Relation Connecting the Derivatives of Physical Quantities, by Mayo D. Hersey; Scientific Paper No. 333, Optical Conditions Accompanying the Striae Which Appear as Imperfections in Optical Glass, by Lieutenant Commander A. A. Michelson; Scientific Paper No. 334, New Forms of Instruments for Showing the Presence and Amount of Combustible Gas in the Air, by E. R. Weaver and E. E. Weibel; Scientific Paper No. 338, Some Optical and Photo-electric Properties of Molybdenite, by W. W. Coblentz and H. Kahler; Scientific Paper No. 339, Standardization of the Sulphur Boiling Point, by E. F. Mueller and H. A. Burgess; Scientific Paper No. 341, Airplane Antenna Constants, by J. M. Cork; Scientific Paper No. 342, Reflecting Power of Stellite and Lacquered Silver, by W. W. Coblentz and H. Kahler; Scientific Paper No. 344, Spectral Photoelectric Sensitivity of Silver Sulphide and Several Other Substances, by W. W. Coblentz and H. Kahler; Scientific Paper No. 345, Measurements of Wave Lengths in the Spectra of Krypton and Zenon, by Paul W. Merrill; Scientific Paper No. 352, Thermal Expansion of Insulating Materials, by Wilmer H. Souder and Peter Hidnert; Scientific Paper No. 358, Concerning the Annealing and Characteristics of Glass, by A. Q. Tool and J. Valasek; Scientific Paper No. 359, Efflux of Gases Through Small Orifices, by Edgar Buckingham and Junius David Edwards; Scientific Paper No. 363, Preparation and Reflective Properties of Some Alloys of Aluminum With Magnesium and With Zinc, by R. G. Waltenberg and W. W. Coblentz; Tech. Paper No. 142, Materials and Methods Used in the Manufacture of Enameled Cast-Iron Wares, by Homer F. Staley; Tech. Paper No. 143, A Study of the Deterioration of Nickel Spark-Plug Electrodes in Service, by Henry S. Rawdon and A. I. Krynitzky; Tech. Paper No. 144, Properties of American Bond Clays and Their Use in Graphite Crucibles and Glass Pots, by A. V. Bleininger; Tech. Paper No. 149, Estimation of Nitrates and Nitrites in Battery Acid, by L. B. Sefton; Tech. Paper No. 154, Determination of Cellulose in Rubber Goods, by S. W. Epstein and R. L. Moore.

How Shall the Government Nitrate Plants Be Operated?

IF THERE is serious and substantial opposition to the idea of the Government operating the nitrogen-fixation plants at Muscle Shoals, it has not been disclosed in organized form at the present writing. On the other hand, there is a growing sentiment in favor of the plan, seeing that two other nations, Germany and Chile, are officially engaged in the nitrogen industry and realize the importance of nitrogen in national welfare. If the United States is to enter these ranks, what shall be the business and commercial machinery for its accomplishment? Shall the War Department undertake the job on account of the close relation between nitrates and munitions? Or shall it fall to the lot of the Department of Agriculture in view of the peace-time importance of nitrogen for fertilizer? Or shall the Department of the Interior be the medium, on the score that nitrogen fixation is a conservation measure and is closely linked with the development of water power?

None of these queries brings an unqualified affirmative answer. And for reasons which we believe will be obvious. A better plan, in our judgment, is contained in the proposal to organize the United States Fixed Nitrogen Corporation, all the stock of which shall be owned by the United States and which shall be free to conduct its business without the restrictions and red tape incident to departmental operation. This corporation would have a working capital with which it must achieve success or failure, and it could not come hat in hand to Congress for annual appropriations with which to conduct its business. Once organized and financed, it would have to stand or fall by its results. It would be free to work like other corporations, and have similar responsibility to its single stockholder, the United States. It would conduct research simultaneously with the development and operation of its plants, and would keep pace with developments in the art of nitrogen fixation so that in emergency the Government would find itself fully informed and in possession of a trained personnel.

Bills proposing such a corporation have already been introduced in both houses of Congress, and hearings have been held by the Senate Committee on Agriculture and Forestry, to which the Senate bill was referred. The House bill has not yet been considered, but it is identical with that of the Senate. The Senate hearing, which is reported elsewhere in this issue, was unusually well organized. The Secretary of War appeared in favor of the bill, and made an exceptionally good statement, showing a grasp of the situation most commendable in a high official. He was supported by officers of the Nitrate Division of the Ordnance Department and by civilian chemists and engineers. There was little discussion of the detailed provisions of the bill itself, the evidence being confined mainly to the necessity of operating the plants and the benefits which would accrue to the country in such an event. Our own discussion of the bill will be reserved to a later date after further study.

In the meantime we favor the general plan as outlined, and expect to present more detailed statements explaining why a United States Fixed Nitrogen Corporation is apparently the best medium for Government operation of the plants at Muscle Shoals. Not the least impressive argument for the plan is the proposed method of financing the corporation without appropriating new funds, the necessary capital being found in the sale of a part of our reserve of Chilean nitrate, which could be safely reduced if the nitrate plants were in regular operation.

Is Pearlite a Special Form Of Widmanstättian Structure?

DR. GIOLITTI elaborates a hypothesis on the crystallography of ferrite which is very suggestive, and which he has found useful in his own practice for many years. For this reason, if for no other, it is undoubtedly worth the careful consideration of those familiar with the eminent Italian's ideas. Unquestionably they will think back over their own experience and justify it, or condemn it, as the majority of instances are marshalled on one side or the other.

Briefly, his idea is this: Many facts seem to indicate that the crystalline habit of beta iron is massive, that of alpha iron laminar. Given correct cooling conditions, then, a micrograph will show rounded particles of ferrite in low carbon iron, and thin striations in the higher carbon areas.

Some recently published illustrations bear out the theory quite strikingly. For instance FOLEY and later CLAYTON have published brief communications in the *Bulletin* of the American Institute of Mining and Metallurgical Engineers, showing pronounced Widmanstättian structure within the pearlite grains of low-carbon nickel-steel ingot runners. Such grains are notably higher in carbon within than at their surfaces, and doubtless the ferrite precipitated directly as alpha iron at temperatures below Ar_1, and, by this new hypothesis, should have a plate-like habit. Yet this structure in FOLEY'S metal, strangely enough, is confined to a thin shell immediately below the outer skin. Why should ferrite from one pearlite grain accumulate in parallel bandings, while that from a closely adjacent grain be finely divided, almost emulsified?

CLAYTON'S photographs are especially interesting in showing swirls of curved ferrite, which he ascribes to

the supposed influence of pre-existing rounded grains of austenite. Could they not more plausibly be regarded as the early stages of growth of a true pearlite grain, with its characteristic laminated structure?

Conceive an undercooled particle of austenite containing approximately eutectoid composition and a nucleus of ferrite to appear somewhere near its center. Reaction spreads outward from this germ with relatively high velocity as from a detonator, alternately producing shells of cementite and ferrite as the wave of transformation passes outward. The succeeding shells would become supersaturated with carbon and with iron alternately, and a characteristic onion-like structure results from the attempt to maintain equilibrium. It seems that a structure should be produced which is somewhat independent of the cleavages existing in the austenite, and might well appear exactly like the swirls photographed by CLAYTON, especially when reinforced by the plate-like crystalline habit postulated by GIOLITTI.

Such speculations as these are extremely attractive to the metallurgist of philosophical propensities, and are not without importance to the ultra-practical, since it is well known that Widmanstättian structure is an undesirable constituent in steels to be used under impact or alternating loads. Yet to know how to avoid it, it is best to know what it is.

Exit the National Laboratory Foundation

PROBABLY few of our readers are familiar with the brief existence of a project known as the National Laboratory Foundation; and if we reverse the usual order by recording its demise without having first announced its birth, it is because we were skeptical of the proposition and preferred to watch its course before approving it. Always there was the feeling that a Senegambian was concealed somewhere in the proverbial woodpile. There was no lack of laudable purpose or commendable object, which was to provide laboratory facilities for invention and research, especially for those who had limited resources. But the original sponsors for the scheme—who were they? and what motives animated them? As far as we were aware none of them was known to science, but they were astute enough to gain for their scheme the tacit approval of famous and reputable men in various fields of scientific endeavor. That those men finally proved quite as astute in fathoming the unethical depths of the plan and refusing to further its success is much to their credit. Just what they discovered we do not know in detail, but doubtless they were led to wonder why a contract had been made with one individual for the payment of a commission on the collection of the proposed endowment. That they discovered evidence of an entangling alliance with the National Institute of Inventors and the National Inventors Sales Corporation, and "their personnel, policies and methods," is disclosed in resolutions condemning the plan and disavowing further responsibility for it. The National Laboratory Foundation was launched with much speaking and dining; it was wrecked on the rocks of personal advantage and private gain. Superficially it was a fine plan, but science and invention would have been scandalized by its success. There is still an opportunity for service by such an institution, but its sponsors, like CÆSAR'S wife, must be above suspicion.

Our Greatest Chemical Industry

COAL utilization is undoubtedly the greatest chemical industry of this country; in fact, it is perhaps our greatest industry of any sort. It includes byproduct coking, locomotive- and stationary-boiler problems, the operation of city gas works, and a multitude of other forms of direct coal utilization in industries, as well as a vast number of byproduct problems of the widest possible interest. Just now there is a very striking development in this great industry that probably has been overlooked by most of our chemical interests. This relates to the city gas works or the coking of coal for municipal gas supply.

Recently two large gas companies have announced plans for installing coking plants for the production of coal gas which is to replace carbureted water gas; and this is only a beginning, with no end of the changes in sight. In 1915, for example, 550 plants produced 136 billion cubic feet of water gas. In more recent years the quantities produced have been even greater and a very large proportion of this water gas, which was made from coke or anthracite and gas oil, must be eliminated and coal gas or coke-oven gas made from bituminous coal substituted. This is essential because of the tremendous increase in the cost of all petroleum products which is making practically prohibitive the purchase of gas oil for water-gas manufacture.

The Washington Gas Light Company announced recently its plans to build a plant to produce 10,000,000 cu.ft. of coke-oven gas per day. The immediate cause of this change was the increase in the price of oil from 7½ cents per gallon on recent contracts to over 12 cents a gallon for offerings now available; and there is some uncertainty whether sufficient quantity is available even at this higher price. Similarly, the Peoples' Gas Light & Coke Co. of Chicago has arranged to build a large coke-oven plant with a capacity of at least 12,000,000 cu.ft. of coke-oven gas per day. These are only two of the significant changes; many more are inevitable throughout the country unless unexpected reductions in the price of petroleum occur in the immediate future. In fact, we can expect that within a few years a hundred billion cubic feet of water gas will be replaced by coke-oven or coal gas.

The production of this gas from byproduct and retort processes will range from 5,000 to 10,000 cu.ft. of gas per ton of coal carbonized, averaging perhaps 7,000 ft. per ton, taking together all the processes that are likely to be used. On such a basis we can foresee the prospective use of 12,000,000 to 15,000,000 tons of coal for carbonization in these plants.

The byproduct production from this large tonnage will be a considerable factor in many industrial lines. There will be 8,000,000 to 10,000,000 tons of coke made, much of it suitable for metallurgical use, the rest probably going into the markets as a substitute for anthracite, especially in the Central and Western territory, where anthracite is now selling at prices much above those demanded a number of years ago.

If such a tonnage of coal is handled, the production of ammonium sulphate will be from 125,000 to 150,000 tons per year above the present production. This represents a very large percentage increase in our supply. But at present the fertilizer industry is finding it necessary to replace many of its organic nitrogen sources such as tankage, dried blood, fish scrap, etc.,

by other nitrogen sources, since these organic ammoniates have reached prohibitive prices. Therefore we can confidently expect the fertilizer industry to absorb readily such portion of this sulphate as may be offered to it.

The same factors which have brought about this tendency to change from water gas to coal gas have, of course, resulted in shortage of motor fuels. Consequently the light oils that we can expect from the carbonization of increasing quantities of coal, amounting to perhaps 30,000,000 to 40,000,000 gal. a year, will very readily be absorbed in the motor fuel industry. As a matter of fact the quantity in prospect will probably not amount to more than a very few per cent of the total motor fuel demand of the country.

Tar production in any such quantities as will follow from great changes in coal-gas production will require rather new industrial chemical developments. Of course our extensive road-building program will afford a large demand for tar, but it is probable that much of the 100,000,000 gal. or more of this material will find its market as a substitute for fuel oil rather than directly in any of the chemical industries.

Although these estimates of byproduct production are based upon a rather extreme assumption of change in character of gas-making processes, and therefore cannot be expected to materialize except during a period of years, yet they represent a very real tendency in our economic system and any one who ignores the trend of these times is likely before long to become very much out of touch with our industrial situation.

The Annual Report Of the Steel Corporation

THE annual report of the United States Steel Corporation, issued in the usual pamphlet form of about fifty pages, 9 x 11 in., in the past week, may be scanned or studied from various viewpoints. From the economic viewpoint an interesting fresh piece of information is that $52,000,000 was deducted from the profits of 1919 as allowance for the Federal taxes, against $274,000,000 for 1918, the decrease being due partly to the rates provided in the law of 1918 being higher for 1918 than for subsequent years, and partly to the total profits having been less. The earnings remaining for 1919, after payment of subsidiary company bond interest, amounted to $143,589,063, a fact known approximately in January, when the report for the fourth quarter was issued, while the tax information is entirely new, since the quarterly report for 1919 differed from those of the two years preceding in containing no statement of the tax allowance. The earnings of $143,589,063 compared with $199,350,680 for 1918, $295,292,180 for 1917 and $333,574,178 for 1916, the corporation's record year. Prior to the war, however, the record was about $160,000,000, made in both 1906 and 1907.

Thus it is seen, from the economic viewpoint, that the Federal income and excess-profits taxes do not bear heavily upon the steel industry, nor upon the consumers of steel, should it be held that the tax is, or should be, passed on to the buyer, for the $52,000,000 tax allowance for 1919, if allocated entirely to the 12,000,000 tons of steel products sold by the corporation, amounts to only $4.34 per ton, the ton which is used being chiefly the gross ton.

From the economic viewpoint there is another very interesting thing in the report. There was $87,091,515 of new construction in the year, and $48,793,661 of this was charged to property account, the remaining $38,297,854 being charged to profits, before the earnings were arrived at. A portion of the latter amount, the exact sum not being stated, represented the cost of making useful for the production of peace material certain facilities the construction of which had been undertaken for war purposes, while the other part was charged off from income on account of the cost having been "extraordinary" because of the existence of "war conditions."

Specifically the report states that the cost of the construction "over what the estimated cost of constructing and installing would have been in the pre-war period was charged off to income." Before the war, which some economists insist has permanently lowered the value of the dollar very greatly, this certainly meaning that properties left intact should be valued in many more dollars than formerly, the Steel Corporation's property account stood at $1,600,000,000. The total expenditures on construction in 1919 amounted to $87,000,000, between 5 and 6 per cent as much. Far from rating its old properties as worth more dollars, by reason of alleged changed conditions, the corporation is not content to charge to property account the entire amount of these relatively modest expenditures, made under what it calls "war conditions," though as a matter of fact the Armistice was signed before the year began.

From the financial viewpoint, one observes that the Steel Corporation, after making allowance for the Federal taxes and after the deductions from income just referred to, had earnings sufficient to take care of all charges and dividends and still leave a surplus of $26,159,781, this being done on an output which is stated to have been 74.5 per cent of capacity, when it has been commonly held in the steel industry that operation under 80 or 85 per cent of capacity is distinctly uneconomical. In the report the corporation renews its expression of confidence in the propriety of the Industrial Board steel prices of March 21, 1919, to which it still adheres. It has higher wages to pay now, as well as increased costs in other respects, but on the other hand it is assured of full operation as far as physical conditions permit, this providing a more economical operation as well as a larger number of tons upon which to make profits.

From the purely physical standpoint, it is interesting to note the statement that operations averaged 74.5 per cent of capacity, when the output of steel products, weighed in the form in which they were sold to outsiders, was 11,997,935 tons. Thus the corporation's estimate of its capacity is 16,200,000 tons per annum, or 52,500 tons per working day. The corporation's record output was in 1916, when physical conditions, while satisfactory for most of the year, distinctly limited output in the closing weeks, and in that year the output was 15,460,792 tons, equal to precisely 50,000 tons per working day. Mill outputs usually increase from time to time even without definite improvements, while there have been some new installations. Thus the present estimate of 52,500 tons as capacity is obviously conservative, and is likely to be exceeded in the near future, as transportation conditions, the only important barrier to full operation, are improved.

Atomic Structure of Metals in Solid Solution

To the Editor of Chemical & Metallurgical Engineering

SIR:—There has been recently some discussion in your columns of an article of mine on the atomic structure of metals in solid solution (CHEM. & MET. ENG., vol. 21, pp. 566-70).

Dr. Jeffries (CHEM. & MET. ENG., vol. 22, p. 100) does not take up the important aspect of the paper, i. e., the agreement between the observed values for the maximum electrical resistance of the binary alloys Ag-Au, Au-Cu, and Cu-Ni, and the values calculated by means of the theory advanced. He makes the suggestion that an alloy of equi-atomic percentages of Ag and Au might be expected to show a sharp break in resistance at the melting range, but he quotes no experimental evidence in its support. So far as I was able to inform myself, there is no datum on this point, either for Ag-Au or any other binary solid solution alloy immediately above the liquidus and immediately below the solidus. Naturally, measurements made on such a system in the melting range where two phases, liquid and solid, are present, would have no definite physical significance.

It is of interest, however, to call attention here to the fact that Northrup (*J. Franklin Inst.*, vol. 182, pp. 477-509) has measured the resistance for the eutectiferous system Sn-Bi and finds for the eutectic composition (58 atomic per cent Sn) no appreciable break in the temperature-resistance curve at the melting point, but simply a point of inflection. Dr. Jeffries' suggestion might be interpreted as applying here with equal force, but the experimental evidence disproves its validity. I can see nothing, other than a direct measurement, which can discredit the assumption that the temperature-resistance curves for binary solid solution alloys, in both the liquid and solid "amorphous state," lie along the same smooth curve.

As an argument against the tenableness of my theory Dr. Jeffries has drawn attention to the existence of heats of crystallization and of fusion in the case of the alloys in question. I would be interested to be referred to such measurements as these in the literature. I admit that cooling curves show the existence of a definite point of inflection at the liquidus, and of a very ill-defined point at the solidus. But these data have not yet been interpreted to give any quantitative idea of the quantities of heat involved in solidification. There are other processes operating in the melting range, particularly the well-known diffusion phenomena, which might be involved in the observed heat effects but which are distinct from the true heat effects of fusion and crystallization.

It was not argued that in passing through the melting range there does not occur a change from the liquid to the solid state, a process involving as its most noticeable accompaniment a change in viscosity. No one has yet claimed any direct relation between viscosity and the existence or non-existence of the crystalline state. Consider, for instance, the substances described as liquid crystals.

The electrical data establish with a degree of certainty, based on an unusual quantitative agreement between the theoretical and observed values of electrical resistance, that the binary solid solution alloys of maximum resistance have a structure in the solid state identical with that of the liquid state so far as metallic conduction is concerned. Now, there are few, if any, properties which are so intimately dependent upon the atomic structure of an alloy as is its electrical resistance. Electron distribution determines largely the atomic combinations, and it is a most important factor in determining the electrical resistance.

We are now brought to an important point of Dr. Jeffries' criticism, and one which was also discussed more fully in Dr. Donald P. Smith's (CHEM. & MET. ENG., vol. 22, p. 340) more recent, excellent comment on the subject of my paper—namely, the existence even in the solid solution alloys of maximum resistance (approximately equi-atomic proportions) of what appears to be a crystalline structure, when examined microscopically as a polished and etched specimen. I take it to be understood that the existence of a "granular" or non-homogeneous structure obtained by an examination of alloys which have been more or less rapidly cooled through the melting interval, and which show the "cores" and dendritic formations caused by the inherent nature of the freezing of solid solution alloys (i. e., difference in composition between liquid and deposited solid at all points other than at a maximum or minimum on the freezing curve) has no bearing upon the present discussion. Homogeneity of structure, obtained by thermal treatment, is a first consideration. I am unwilling to admit that in the case of such a homogeneous structure the appearance of what are called "grains" by the metallographist is conclusive evidence of the existence of a crystalline structure, in the true meaning of the word. I can conceive of the existence of a granular structure in a perfectly amorphous solid.

It might be well to call attention to the fact that it has been quite customary to attribute a definite melting point to a crystal, to distinguish it from a mixture. However, a binary solid solution crystal, if such, perchance, exists at equi-atomic concentrations, does not melt at a constant temperature. Hence, the "crystalline" structure of solid solution alloys must be of a different type from that of ordinary crystals, and the crystallization phenomena at the melting range must be correspondingly modified. According to my theory, based on an independent quantitative relation which exists regardless of the validity of the theory, crystallization in binary solid solution alloys of maximum resistance is modified to such an extent that the atomic structure of the solid alloy is identical with that of the liquid. If it is conclusively shown that the solid alloys are crystalline, then I will modify my theory to the extent of assuming that the same type of crystalline structure exists in the liquid alloys.

I do not fully understand the significance of Dr. Jefries' reference to "the directional and deformational characteristics of solid solution alloys." The components of the systems studied belong to the cubic system. Hence the only directional characteristic to be expected is that of the three crystalline axes, determinable only in the case of idiomorphic crystals. Since we are not dealing with idiomorphic crystals, and I do not believe they have been observed in the cases under considera-

tion, I am unwilling to admit without further evidence that slip-bands are dependent upon or are determined by cleavage planes corresponding to the existing direction of these axes. Cleavage planes are found in some amorphous bodies.

According to recent investigations of Tammann (*Nachr. Kgl. Ges. Göttingen*, 1916, pp. 199-265; 1917, pp. 345-72, 385-425), the difference between a "mixed crystal" and a chemical compound depends upon the electrons surrounding the positive core. For solid alloys of the systems Ag-Au and Cu-Au it was found that the atoms were present in the free state, while Au-Zn alloys form a compound in equi-atomic proportions. These conclusions were reached from experiments on galvanic potential. Moreover, certain well-defined limits of resistance to galvanic attack were found, with respect to the composition, of such solid solution alloys as Au-Ag and Au-Cu. There may well be a certain relation between these observations and the formation of an increasing amount of solid amorphous metal with increase of concentration.

I wish finally to call attention to a misprint in Dr. Smith's discussion. In the first paragraph, Ag-Cu should read Au-Cu.

The Technical Engineer's Judgment of the Oxy-Acetylene Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—The writer is interested to note the article in your issue of Feb. 4, 1920, entitled "The Technical Engineer's Judgment of the Oxy-Acetylene Process," by Alfred S. Kinsey. In the paragraph on "Forge Welding," Mr. Kinsey states:

"Up to the advent of autogenous welding the engineer had only his experience with the forge weld upon which to base his calculations and judgment. In a way this proved somewhat unfortunate for the new method of welding, as the forge weld has nearly lost its value as a dependable means of joining metals. Imagine two pieces of steel being brought to a soft plastic condition in a forge fire charged with sulphur from the fuel, an excess of oxygen from the indifferently operated bellows or fan blower, the cinders and refuse of the fuel, and one can readily realize the cause of weak forge welds. Such welds never were reckoned to have a tensile efficiency of more than about 50 per cent, and many observations of welds which had failed showed crystallization and even entrapped cinders. Navy yards and many other large shops had practically abandoned the forge weld, preferring the expensive substitute of machining a job out of the solid when it was possible to do so. Serious failures of forge welds were too common."

Mr. Kinsey is absolutely correct in his judgment of a forge weld as made by the process which he so aptly describes, but he seems to lose entire account of the fact that other processes of forge-welding, with improved methods of heating, have been developed since the days of the prehistoric blacksmith, which eliminate the very causes which he speaks of as being detrimental to a good weld—such as sulphur from the fuel, cinders and refuse, excess of oxygen by the blower, etc.

There are several advantages in joining metal together in its "plastic" condition which are completely overlooked by Mr. Kinsey in his article—such as the fact that the metal is not heated up to the point where it will absorb either oxygen from the air or carbon from the acetylene arc, as is the case from the carbide flame; that its chemical characteristics after being welded are not materially changed; and the vigorous working which it gets, which actually reduces areas and thereby distinctly changes the granular construction, greatly assists in the welding of the two pieces together under a hammer.

The advent of modern apparatus for heating the plates under an absolutely controlled condition of temperature, and the working under heavy, high-power-driven hammers, thus assuring a complete working of the metal and the breakdown of the crystalline structure, have made it possible to make forge welds whose efficiency and general dependability are far above any that can be made by the oxy-acetylene or any other known process. The range of thickness encompassed by the autogenous-welding process is extremely limited, whereas the forge-welding as done by modern apparatus is applicable to very heavy plates, and has been used successfully under pressures and temperatures far above any that have ever been attempted for autogenous-welded receptacles.

When the autogenous-welding process can be developed up to the point where it can make a cylinder, for example, 5 in. in diameter, of 1½-in. plate, to stand a working pressure of 500 lb. and a temperature of 900 deg. F., and prove absolutely dependable for such service, it will then be safe to say that it has reached the point where it is as dependable as forge-welding by modern processes.

The old-fashioned forge weld as described in Mr. Kinsey's article is acknowledged to be just as unreliable as the autogenous weld made under relatively the same unfavorable conditions, and a long series of experiments and a thorough training in technique have been necessary to develop either of them to the point where they are today.

Distribution of Apparatus and Reagents for Laboratory Courses

Prof. W. L. Estabrooke, of the department of chemistry of the College of the City of New York, described in a late number of *Science* the operation of the Freas system in distributing apparatus and reagents in a general chemistry laboratory. By this plan each student receives on his first day all the apparatus and chemicals he will need for the course and he is given just enough of each chemical to perform his experiments plus a slight excess. Should he be careless and need more he must go to the storeroom and sign for his needs, which are charged up to his breakage and "excess chemicals" deposit.

The prices on his list are the same as those charged at the nearest apparatus house, so he has no temptation to take things home. And it provides a great inducement for clean and orderly work, as well as effecting a great saving in chemicals.

It also increases the amount of work done in the given time during the course, compared with the still common, old side-shelf reagent system. In one laboratory Prof. Estabrooke computed that a student was likely to walk from thirteen to twenty-six miles during one term to go from his bench to the side shelf and back to procure needed chemicals.

Senate Hearings on U. S. Fixed Nitrogen Corporation Bill

HEARINGS on the bill to establish the United States Fixed Nitrogen Corporation were begun before the Senate Committee on Agriculture and Forestry Monday morning, March 22. This is a bill authorizing the Secretary of War to designate five persons for the purpose of organizing a corporation "to purchase, acquire, operate and develop . . . United States nitrate fixation plants numbered 1 and 2, located, respectively, at Sheffield, Ala., and Muscle Shoals, Ala." All of the capital stock of the corporation is to be owned by the United States, the common stock being issued for the properties acquired from the United States, and the preferred stock for the sum of $12,500,000 with which to complete and operate the plants and develop the art of nitrogen fixation. The plan was proposed to the Secretary of War by Arthur Glasgow, who made recommendations regarding the utilization of our nitrate plants, on the return of our military and agricultural commissions from Europe last fall. The object is to maintain the plants in peace-time operation for the production of nitrogen fertilizer compounds, and at the same time enhance their military value through the experience gained in operation and in contemporaneous research in the science and art of nitrogen fixation.

Secretary Baker was the first witness before the committee. He stated that three plans were open to the Government in disposing of the plants: First, to scrap them and secure what salvage value they represent, which would be admittedly low; second, to keep them in stand-by condition for the use of the War Department in emergency; or third, to operate them on a peace-time basis for the production of nitrogen fertilizer compounds. He showed that the pre-war requirements of the United States in Chilean nitrate amounted to 500,000 tons per annum, and that with the plants producing ammonium sulphate and other nitrogen compounds at their full capacity we would still have to import from Chile. Being questioned as to the proposed products of the plants, the Secretary stated that these probably would be ammonium sulphate, ammonium nitrate, calcium cyanamide and possibly ammonium phosphate. He said he was not converted to the extensive use of cyanamide as a fertilizer and would not like to see the plant make this as its only product. For this reason it would be necessary to add equipment for the manufacture of other nitrogen compounds.

Plan for Securing Necessary Funds

The most important development in the Secretary's testimony was the proposal, originally suggested by Colonel Burns, that the $12,500,000 necessary for financing the proposed corporation be obtained from the sale of half of the present reserve stock of Chilean nitrate now held by the War Department. The safe reserve of nitrate which it is considered necessary to carry in this country is 300,000 tons, and the War Department has now sold from its supply down to that figure. With the nitrate plants in operation, however, it would be safe to reduce this reserve to one-half, or 150,000 tons, and the sale of that quantity at present prices would provide the money for financing the new corporation. This would make it unnecessary for Congress to appropriate new funds for this purpose, as proposed in the original draft of the bill. The Secretary, therefore, suggested to the committee an amendment striking out the appropriation clause and substituting authorization to sell 150,000 tons of Chilean nitrate from the present reserve stock and subscribe the proceeds to the capital stock of the corporation. This is evidently regarded as a strong point in favor of the general plan, because it will forestall objections against new appropriations of public funds.

Additional advantages to be gained from the sale of a part of the reserve stock of nitrate were presented by General Williams and Colonel Burns. It appears that part of the reserve is carried in Government storage warehouses at interior points and part in commercial warehouses at the seaboard. The latter must eventually be transported to interior points and new warehouses must be constructed for its storage. General Williams stated that the sale of 150,000 tons of the reserve would obviate the expenditure of about $1,800,000 in new construction and freight. Colonel Burns stated that the cost of storage of 150,000 tons of nitrate for six months, partly in Government and partly in commercial warehouses, would cost over $100,000, all of which would be saved if the nitrate were sold.

The Secretary stated that one important reason why the Government should plan to operate these plants is that the whole question of nitrogen fixation is in a state of flux and that a vast amount of development and research work must be prosecuted before we know what products are best for various fertilizer purposes. He felt that the Government, which has no private interests to advance or special products to promote, could operate the plants and conduct research in such a disinterested way as to be of the greatest benefit to the country.

Plans Presented by General Williams, Colonel Burns and Prof. White

General C. C. Williams, Chief of Ordnance, reviewed for the committee the general pre-war situation in this country regarding nitrogen compounds, and followed that with a brief history of the development of nitrate plants. Plant No. 1, using the synthetic ammonia process, was experimental and was not in successful operation at the time of the armistice. Plant No. 2, using the cyanamide process, was practically completed at armistice, and had been built because it was based on a proved process in which American engineers had had experience. The cyanide plant at Saltville, Va., was built to make cyanide for poison gas, but was experimental, and the process proved too costly as a method of fixing nitrogen for commercial purposes. In summarizing the present situation, General Williams suggested a program as follows: Proceed with development and research in the art of nitrogen fixation; make No. 1 Plant effective through such research and development; operate No. 2 Plant with the production of appropriate nitrogen compounds; and complete the Wilson dam at Muscle Shoals for the production of the necessary electric power.

Colonel Burns reviewed for the committee the history of the use of nitrates in military operations, and pointed out the need of nitrates in the manufacture of explosives, fertilizers and chemicals. His written statement will be printed in the record.

Methods of nitrogen fixation were outlined by Prof.

Alfred H. White, formerly an officer in the Ordnance Department. Eliminating the arc process as one requiring tremendous quantities of cheap power, the two processes which have gained commercial importance are the cyanamide and synthetic ammonia. These two processes were briefly described, and the technical difficulties of the synthetic process were compared with the simplicity and high degree of perfection of the cyanamide process.

Data Presented by Prof. White

Prof. White presented many interesting charts and figures showing the world's production of inorganic nitrogen, growth in fixation of inorganic nitrogen, and future development of nitrogen fixation in the United States. Tables I and II contain the essential facts.

TABLE I. WORLD'S PRODUCTION OF FIXED INORGANIC NITROGEN EXPRESSED IN METRIC TONS OF NITROGEN

	1908	1913	1917	1920
Chilean nitrate	300,000	390,000	392,000	500,000
Byproduct ammonia	212,000	343,000	364,000	410,000
Atmospheric nitrogen:				
Cyanamide process	2,500	60,000	200,000	325,000
Arc and miscellaneous process	3,000	18,000	30,000	32 500
Haber process	.....	7,000	110,000	308,000

TABLE II. WORLD'S PRODUCTION OF ATMOSPHERIC FIXED NITROGEN IN METRIC TONS OF NITROGEN

	1909	1913	1917	1920*
Arc and miscellaneous process	3,000	18,000	30,000	33,600
Cyanamide process	2,500	60,000	200,000	325,000
Haber process	.....	7,000	110,000	308,000
	5,500	85,000	340,000	666,600

* Estimated maximum in possible production.

Other interesting data presented by Prof. White dealt with the domestic sources of fixed nitrogen in the various countries compared with the population. The United States is near the bottom of the list, coming ahead of only Italy and Austria. The following figures express tons of nitrogen per million of population: Germany, 8,760; Norway and Sweden, 7,250; Great Britain, 2,240; Canada, 2,200; France, 1,850; Switzerland, 1,840; United States, 1,480; Austria, 630, and Italy, 630. In closing, Prof. White stated that the field for nitrogen fixation in the United States was clearly one for Government operation if there ever was one, for both Germany and Chile are in the business on that basis and will struggle to dominate the world's supply of nitrates. The field is not an attractive one for private capital.

Report of Colonel Joyes

Colonel J. W. Joyes of the Ordnance Department, who made a trip to Europe as chairman and member of the U. S. Fixed Nitrogen Commission, made a report of some of his observations and studies in foreign countries, particularly in occupied German territory. Germany has a present capacity for fixing nitrogen of about 300,000 tons by the Haber process, 120,000 by the cyanamide and 150,000 by coke ovens and gas works. He gave figures (Table III) on capacity in different countries probably available for commercial production of fixed nitrogen.

Colonel Joyes stated that inspection of Germany's Haber plant at Oppau indicated great need of further improvement for satisfactory operation. He was impressed with the fact that labor and supervision forces must be quite large, although the expense for these items had not been large due to the low wages paid up to 1914. It has been stated that ammonia was made in this plant for four cents per pound in 1914-15, but Colonel Joyes was convinced that present costs would be at least two and one-half times as much.

TABLE III. PROBABLE COMMERCIAL PRODUCTIVE CAPACITY OF WORLD NATIONS OF FIXED NITROGEN IN METRIC TONS OF NITROGEN

	Haber	Cyanamide	Arc	Total
Germany	300,000	93,000	...	393,000
France	.....	40,000	1,000	41,000
Italy	.....	12,000	1,000	13,000
Scandinavia	.....	28,000	30,000	58,000
Austria	.....	22,000	.....	22,000
Switzerland	.....	7,500	.....	7,500
Japan	.....	12,000	.....	12,000
Canada	.....	12,000	.....	12,000
U. S. (Plant No. 2)	.....	40,000	.....	40,000
Total	300,000	266,500	32,000	598,500

Assuming the same plant set down in the United States in a favorable location, cost of production of ammonia under present price conditions would be approximately:

	Cost of Ammonia — Short Ton		Pound	
Operation and upkeep	$209 to $163		$0.105 to $0.082	
Amortization	75	50	.038	.025
Interest	45	45	.022	.022
Sales	2	1		
	$331 to $259		$0.165 to $0.129	

Interest is figured at 6 per cent on $750, which is the assumed per-ton cost of the plant. Upkeep is taken at 10 per cent and amortization at 10 per cent.

The organization of the German Stickstoff Syndikat, or nitrogen syndicate, and the method of government operation and control, was described in some detail by Colonel Joyes. The capital stock of this syndicate is held by three different groups of industrial companies, each of which has a member on the board of directors, the government having the fourth. There will also be a board of managers, the chairman of which will be appointed by the government. The management will determine the production of various nitrogen compounds and their distribution.

Statement of Colonel Lamb

Colonel A. B. Lamb, late of the Ordnance Department and now in charge of the Nitrate Division's research laboratory at American University, Washington, made a statement in which he stressed the necessity of continuing research in the art of nitrogen fixation. Starting with the assumption that the United States must meet foreign competition in nitrogen fixation as a matter of national welfare and safety, if for no other reason, he outlined briefly the different possibilities in producing nitrogen-bearing compounds such as ammonium sulphate, ammonium chloride, urea, ammonium phosphate, etc. The location of the Muscle Shoals plants near deposits of phosphate rock and potash-bearing minerals and a source of cheap water power afforded an opportunity to develop new fertilizer materials in addition to nitrogen. Research has been the fundamental factor in industrial development in Germany and elsewhere and must be continued in this country. It is not enough to know what the Germans or any other people are doing, or what their formulas and methods are; that is only part of the story, to be supplemented with local experience and the training of skilled operatives.

Statements by Major Gaillard and Others

A statement by Major D. P. Gaillard, Ordnance Department, covered the demand and supply of inor-

ganic nitrogen in the United States and the necessity for fixing atmospheric nitrogen. He showed that the diversion of the organic ammoniates, such as cottonseed meal and tankage, from use in fertilizer to feed for animals, was taking that source of nitrogen away from the fertilizer industry. His statement was supplemented by instructive charts and figures. His estimate of the domestic peace-time consumption of inorganic nitrogen in 1924 was 294,500 tons, with an estimated domestic supply of 122,500 tons, leaving a deficiency of 172,000 tons. By 1930 the consumption is estimated to be 438,000 tons with a supply of 184,500, leaving a deficiency of 353,500 tons. If the Government nitrate plants are put in operation and produce 45,000 tons of nitrogen in 1924 and 55,000 tons by 1930, there will still be deficiencies of 127,000 and 198,500 tons respectively.

In addition to the foregoing testimony the printed record of the hearings probably will contain a statement by George J. Roberts on the estimated cost of operation at Muscle Shoals and a justification of the capital requirement of $12,500,000 requested in the bill. The recommendations of Mr. Glasgow mentioned in the beginning of this report will also be included.

Engineering Advertisers' Association

At the meeting of the Engineering Advertisers' Association of Chicago held March 9 at the Auditorium Hotel, the following officers were elected for the ensuing year: President, A. H. Hopkins, adv. mgr., C. F. Pease Co.; vice-president, J. J. Arnsfield, adv. mgr., Fairbanks-Morse Co.; secretary, G. S. Hamilton, adv. mgr., American Steam Conveyor Corp.; treasurer, E. I. Pratt, adv. mgr., Kellogg Switchboard & Supply Co.

Increased production is the topic of the hour and the Engineering Advertisers' Association in its efforts to improve the methods of advertising and selling engineering products will accomplish an object worthy of attainment and vital to every one. The present membership of the association is one hundred. Any man engaged in advertising or selling engineering products is eligible to membership.

President-elect Hopkins earnestly suggested that the members continue the splendid co-operative spirit that has marked the first year of the Association and emphasized the importance of the work to be done.

Immigration Conference

A national immigration conference will be held April 7 in New York City in the Engineering Societies Building, 29 West 39th St. National leaders in American industry and finance will discuss the shortage of foreign-born labor and the loss of production due to unrest among the workers, and measures will be taken for united action to relieve this condition.

Invitations to attend this conference have been issued by the Inter-racial Council to more than a thousand of the directors of industrial concerns, especially those employing foreign-born labor, and to others interested in this problem from the standpoint of finance or national welfare, including racial leaders. Topics to be discussed will include pending bills on immigration, and a constructive policy will be proposed and voted upon. All industrial executives are invited to be present. Further details may be secured by addressing Coleman du Pont, chairman of the board, the Inter-racial Council, 120 Broadway, New York City.

Further Changes Proposed in Dye Bill

AN AMENDMENT which removes the embargo clause in the dye bill has been introduced by Senator Moses of New Hampshire. It is known that the amendment has many friends among Senators.

Additional Duties Instead of Embargo

Practically the whole of the bill, with the exception of section 500 (which enumerates the commodities in the three groups and their respective duties), has been revised. Instead of prohibiting the importation of articles in groups II and III, the amendment permits their entry, but on such articles as are being manufactured and offered for sale on a substantial scale in the United States another duty must be paid in addition to the duties provided for in section 500. This additional duty is equal to the difference between (1) the sum of the dutiable value of the article plus all nondutiable costs, charges and expenses incident to importation, and any duty imposed by section 500, and (2) the fair wholesale selling price in the United States of a like article or satisfactory substitute of domestic manufacture plus 20 per cent of this price. In connection with this section:

> The term "fair wholesale selling price" of an article means the lowest wholesale price sufficient to insure the maintenance in the United States of the production of such article by an efficient plant operating on a scale reasonably adequate to supply ordinary domestic demands; and the term "satisfactory substitute" means an article capable of giving results in use substantially equal to the article for which it is proposed as substitute. The Secretary of the Treasury shall from time to time determine what is such "fair wholesale selling price" and such "satisfactory substitute."

Tariff Commission to Protect American Industry

Whenever the Tariff Commission, after proper investigation, decides that any article in this act is being imported under conditions which constitute a menace to the industry in this country, the Secretary of the Treasury will be notified and importation of the product will be prohibited until further notice from the Tariff Commission.

Whenever the Tariff Commission has reason to believe that a person is offering for importation any products in violation of this section, but has not information sufficient to determine whether it should certify that fact to the Secretary of the Treasury, the Secretary of the Treasury shall, upon request, forbid entry to such products until the Commission completes the necessary hearings; but the Secretary of the Treasury shall permit conditional entry of such products under bond.

Treasury Department to Secure Data

The Secretary of the Treasury has the right to inspect factories and accounts of any domestic producers of artcles in groups II and III. The information secured in this way shall be confidential and shall not be published except in the form of totals or averages which do not disclose the operations of individual manufacturers. In the present form of the bill this power is delegated to the Tariff Commission.

Another amendment, by Senator Spencer of Missouri, adds the following items to the bill: Camphor, natural and synthetic, crude and refined, 25 per cent; caffeine, $1.50 per lb.; chloral hydrate, 15c. per lb.

Crystallography of Alpha and Beta Iron

A Complete Classification of the Various Microscopic Appearances of Hypo-eutectoid Steels Based Upon the Hypothesis That Alpha Iron Has a Plate-like Habit While Beta Iron Has a Granular Habit

By FEDERICO GIOLITTI

NICOLAS BELAIEW, writing in the *Revue de Métallurgie*, 1910, p. 510, on "An Artificial Reproduction of Widmanstättian Structure in Carbon Steel," has brought to a successful conclusion the long and interesting series of attempts to reproduce the structure of meteoric iron in the laboratory. Osmond and Cartaud had already established the conditions of its formation as being extremely slow cooling, as compared to that of ordinary laboratory experiments. Such slow cooling gives time for a more or less complete decomposition of the non-magnetic solid solution existing in iron-nickel alloys at high temperatures, to the effect that the excess constituent is deposited along crystallographic planes parallel to faces of a regular octahedron. Belaiew, in turn, was able to reproduce in pure steels containing about 0.50 per cent carbon a completely analogous structure by the combination of a long high heat followed by extremely slow cooling. A glance at the micrograph, Fig. 1, showing one of his laboratory samples, and Fig. 2, meteoric iron from Tazewell, is sufficient.

Fig. 2. Widmanstättian structure in Tazewell meteorite. × 3.

Widmanstattian Structure

This author calls attention to the essential similarity between the equilibria of iron and nickel as determined by Osmond[1] (Fig. 3) and the well known iron-carbon diagram (Fig. 4). Inspection shows that both non-magnetic iron-nickel alloys and iron-carbon solid solution (austenite) decompose after solidification and on slow cooling into their constituents, of which the substance camacite corresponds to ferrite, taenite to cementite, and the eutectoid plessite is equivalent to the eutectoid pearlite. Consequently the phenomena attending a cooling of corresponding alloys are similar: primary crystallization passes through a mushy stage forming interlocked dendrites, whose habit in both cases is ordinarily the regular octahedron. Further cooling—extremely slow for meteorites — favors a uniform orientation of the individual crystallites forming the solid solution into masses which are essentially huge allotriomorphic crystals. Upon cooling to the point where solution is saturated, secondary crystallization takes place; for low-nickel alloys, camacite separates from a constantly enriched solution, which latter finally breaks up into the eutectoid plessite. For low-iron alloys, ferrite first separates and the enriched austenite finally reaches eutectoid composition and reverts to pearlite.

Belaiew then points out that on extremely slow cooling one can expect super-cooling and spontaneous crystallization in large masses; a crystallization, it is important to note, from an already crystalline substance, under which condition it is commonly admitted that the subsequent phase collects along the crystalline planes of the precedent phase. He therefore argues that Widmanstättian structure depends entirely upon the orientation of the crystalline mass and in steels is independent of their carbon content. Therefore Osmond has been able to develop the same appearance in slowly cooled "burned" Swedish iron, and Belaiew also found very pronounced Widmanstättian structure in slowly cooled hyper-eutectoid steel.

Structure of Great Crystals and Reticular Structure

Two years later *Stahl und Eisen*[2] printed an abstract of Chapter III of a Russian treatise by Captain Belaiew, "On the Crystallization and Structure of Slowly Cooled Steels," in which he notes the occurrence and describes the mode of formation of three distinct crystalline habits in such metal. He points out that during original

solidification it is well known that the time in the mushy state and the difference in carbon concentration axis to center are ordinarily greater, the higher the carbon in the melt. (In other words, the liquidus *AB* and the solidus *AE* in Fig. 4 markedly diverge as carbon increases.) Slow secondary crystallization resulting from the austenitic dendrites formed during the mushy stage then causes:

First, excess ferrite to separate where there is the least and cementite where there is the most carbon in a non-uniform solid solution. Therefore ferrite appears at the axes of such hypo-eutectoid dendrites and cementite at the contacts of hyper-eutectoid dendrites. This results in what Belaiew calls "structure of great crystals," and is illustrated in Figs. 5 and 6.

Second, in solid solutions rendered homogeneous by long annealing or very slow cooling, ferrite (or cementite) is excluded to the borders of the primary crystals if the slowness of cooling from Ar_3 to Ar_1 is sufficient in comparison with the size of the dendrites so that the excess constituent can migrate the necessary distance. In such cases the microscopic appearance often seen in well-made commercial steels results. Belaiew calls it "reticular structure" (Fig. 7), whose network veins are the thicker the further the carbon content in the steel from the eutectoid.

Third, in homogeneous solid solutions cooled somewhat too rapidly for the excess constituent to reach the periphery of the austenite crystals, the bulk of it remains inside the original austenite grains, but seeks the crystallographic planes of octahedral primary crystallization, forming Widmanstättian structure (Fig. 1).

Belaiew goes on to point out that two or three of these structures may appear in the same piece of steel—for instance, network surrounding Widmanstättian areas is quite common. Apparently excess constituent preferably crystallizes about foreign inclusions such as slag and graphite, or on the walls of cavities. By very long cooling cementite sometimes crystallizes in its characteristic needle-like forms, following only the directions impressed by the octahedral austenite, in which case an aggregation of crystals results and not crystalline groups.

Structure From Equalized Austenite

After reading the articles of which the foregoing is a review, I communicated a paper to the Academy of Science of Turin on March 30, 1913, giving some observations on a piece of metal whose structure did not correspond to Belaiew's dicta. The sample in question consisted of a piece of sheet steel which had formed a heat-treatment muffle, whose interior had been filled with wood charcoal, and whose exterior had been constantly bathed by oxidizing gases. It had been heated about five months continually from 900 to 1,050 deg. C., never, even for a short time, falling below the lower temperature. It had been cooled in the furnace setting, requiring about 4½ days to drop from 1,000 deg. C. to 150 deg. C.

Its average analysis follows:

Mn	0.40	Si	0.011
P	0.059	C	0.32
S	0.011		

Carbon, of course, varied uniformly from about 1 per cent at the inside to practically zero at the outside, due

to the fact that during use the carbon oxides had diffused continually through the metal.

Its very long sojourn at temperatures well within the austenitic area (*AGOSE*, Fig. 4) had given opportunity for even slowly moving soluble segregations to equalize their distribution throughout the metal. Continual diffusion of $CO:CO_2$ in equilibrium had also undoubtedly obliterated any non-uniformity in carbon which existed between axes and edges of the dendrites of primary crystallization and inherent by the mode of solidification. While it is not strictly true to say that the austenitic crystals were absolutely uniform in carbon concentration, since the plate is high in carbon at its inner edge and carbon free at its outer, still this uniform gradient across the plate is entirely independent of the older non-uniformity caused by solidification of mixed crystals.[2]

Consequently Belaiew's conditions for the "structure of great crystals" are absent. Furthermore, the cooling from Ar_3 to Ar_1 was much slower in the furnace than that occurring in moderate sized pieces of cast steel in air which ordinarily exhibit Widmanstättian structure. Belaiew's views would require such a piece to have a "reticular" structure, yet Fig. 8, at 60 magnifications, shows a field of this metal having very coarse crystals and perfectly developed Widmanstättian structure!

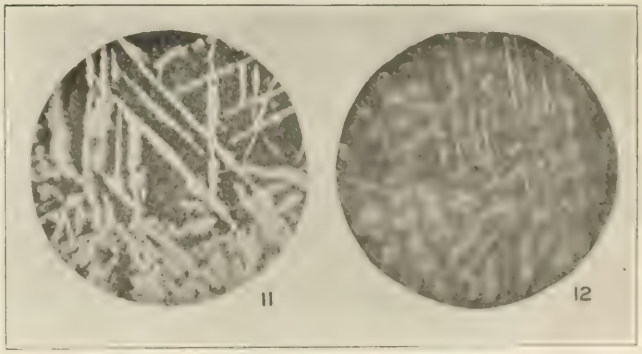
Two 300-g. pieces like Fig. 8 were reheated for 8 hr. to 1,000 deg. C., one air cooled (½ hr. to 150 deg. C.) and the second furnace cooled (4 hr. to 150 deg. C.). At the end their microscopic appearances at 60 magnifications were as Figs. 9 and 10 respectively, thus demonstrating that at least for this particular steel very slow cooling favors perfect Widmanstättian rather than reticular structure. One should remember, however, that the history of the steel was quite different from the ordinary heat-treated pieces, whose time in the zone of gamma iron is too short for total equalization of all carbon, phosphorus and other elements forming solid solutions.

Two Crystalline Habits Distinguished

All cross-sections of the steel plate previously described, which when studied showed a wide range in carbon, also exhibited two distinct forms of ferrite crystals, the one characteristic of regions containing less than 0.4 per cent, where the ferrite existed in rounded grains common to ordinary soft steel, and the other characteristic of higher carbon regions, where the ferrite existed as needles or striations in concordant groups, an appearance common to Widmanstättian structure. Both these crystalline habits are shown in Fig. 11, at 20 diameters.

Considering the history of the specimen, it is certain that all crystals of ferrite have formed from a solid solution free of "nuclei" of low-carbon content, and all have separated under precisely the same cooling conditions. The only difference in the condition of formation is that the rounded grains formed first, and at a higher temperature. In other words, the rounded particles separated from austenite as β iron along the line *GO* (Fig. 4) down to about 760 deg. C., while the plate-like laminations formed themselves as α iron along the line *OS* at a temperature below 760. In the first case the crystals of β iron were largely developed and then transformed bodily into α iron at 760 deg. As cooling continues, the last traces of excess ferrite separate themselves directly as α iron, but meeting with already-formed germs of crystallization, they deposit upon them, following their form.

Granting this, the first crystalline appearance separating from *uniform* low-carbon austenite and developing in large part above 760 deg. C. should be that characteristic of β iron—not rigorously in all crystallographic particulars, but possessing those morphological external characters of crystalline forms upon which depend many mechanical properties of the metal. The second crystalline appearance, separating from uniform austenite con-



Figs. 11 and 12. Microstructure of cementation muffle where carbon concentration passes 0.4 per cent. Etched in 5 per cent picric acid in alcohol. × 20.

[2] I use the term "mixed crystals" in the European sense, meaning to us what "solid solution" means to Americans.

taining somewhat more than 0.5 per cent carbon and developing entirely below 760 deg. C., should be that characteristic of α iron.

Confirmatory Observations

A few of many possible confirmatory observations may be cited to substantiate the theory just advanced that β iron has a roundish, granular habit, while α iron has a flat plate-like habit, which I think satisfactorily explains the origin of all characteristic appearances of hypo-eutectoid steels.

Figs. 11 and 12 represent the structure, magnified 20 times, of that zone of the steel plate where the carbon content passes the point *O* (Fig. 4), from low carbon at the bottom nearly to eutectoid at the top. In each of these figures the features just explained may be seen; grains of ferrite in the low-carbon area which precipitated as β iron, and needles in the higher carbon area, which precipitated as α iron. Along the border zone between the two types of crystals one clearly sees some which may be called "composite," which have simultaneously the morphological characteristics of both series. By the theory, they should have roundish nuclei of β iron upon which form needle-like appendices of α iron. Actually this occurs, according to the well-supported hypothesis that slowly forming crystalline material of a second series deposits itself by preference on pre-existing nuclei, reproducing those contours only in cases where the originally formed mass is sufficiently preponderant in comparison with that of the later additions.

If my hypothesis be true, one must expect that should the crystallization process be disturbed by forging or other mechanical work, a barrier would be presented to the deposition of the α plates upon β granules, copying and preserving the roundish forms, and in such cases one would find α and β forms separating out in large part independently, and finally appearing side by side. Actually, Portevin and Bernard[4] show excellent micrographs of this kind, three of which are reproduced in Figs. 13, 14 and 15. Those authors, however, ascribe the appearance of Widmanstättian bands in forging to the fact that the pieces were held for a long time in the heating furnace at a temperature above 900 deg. C. (in Belaiew's "zone of granulation"), and the subsequent cooling was rapid enough that the excess ferrite collected along the octahedral planes of the pre-existing austenite.

Consider the case of a mass of uniform austenite. After relatively rapid cooling my theory would call for a final appearance analogous to that of mechanically disturbed crystallization. This is exactly the case in regions of low-carbon content in Figs. 9 and 10.

Classification of Non-segregated Metal

On the hypothesis that ordinary slowly cooled steel has superimposed in it two processes of crystallization, the final structure of steel depends mainly upon the uniformity of austenite, the speed of cooling through the critical range, the mechanical disturbances, and the carbon content.

1. For steels which have undergone treatment for *total* equalization of carbon, axis to periphery of each primary dendrite, the following classification holds:

A. Cooling very slow (furnace cooling) and undisturbed mechanically.

a. Carbon less than 0.35 per cent. Nuclei of β iron are prominent. Only those portions separating at temperatures less than 760 from a residue of enriched austenite come down as α iron, and even this tends to deposit on pre-existing masses of iron, also now transformed to α iron but pseudomorphous after β. Only in case the α iron formed in the second phase of cooling should be in preponderance can they develop in a noticeable measure by the side of the β appearances. (Figs. 11 and 12).

b. Carbon more than 0.4 per cent. All ferrite crystallizes directly into α iron, assuming its characteristic form well known as Widmanstättian structure (Fig. 8).

B. Cooling slow, and undisturbed mechanically.

a. Carbon less than 0.35 per cent. Crystallization takes place again in two steps as described above in *A,a*, separating as β and α iron successively. But in this instance the α iron cannot be so strongly influenced by the preformed β iron as formerly, and independently segregates into its own form. (Fig. 10.) Naturally the smaller speed of cooling will not permit α and β crystals to reach such large dimensions or perfect form, and the Widmanstättian structure degenerates into distorted striations.

b. Carbon more than 0.4 per cent. The structure still shows Widmanstättian bands but much more

imperfectly, in proportion to speed of cooling. If it is somewhat fast, the deformation of the ferrite crystals is sufficient to mask the plate-like structure.

C. Cooling slowly, with mechanical work finished very hot. Crystallization takes place analogous to *A,a* and *B,b*, but the effect of primary β crystals is less marked; the deformation separates efficaciously the elements formed in either phase. (Fig. 14.) In case the mechanical work is continued through the transformation range, all crystals are broken up and their original forms destroyed.

D. Cooling rapidly, with mechanical work, as in small drop forgings or stampings. Resulting forms are analogous to *C*, but the various crystalline elements are very small and often so poorly developed that it is difficult to distinguish one from the other.

Classification of Partially Equalized Metal

2. Some steels have had a prolonged annealing at high temperature, or a preliminary heating followed by a reheating at a lower temperature, yet the carbon content of the austenite crystals has not been completely equalized. Even in this case the phenomena proceed in a manner analogous to case 1, depend upon the same principal conditions, and are only modified by the presence of local difference of carbon concentration in each austenite crystal.

A. Cooling very slow (furnace cooling) and undisturbed mechanically. The first iron separates at those places where the carbon concentration is least, which ordinarily coincide with the nuclei of primary austenite. On account of the slow cooling over the temperature range corresponding to the separation of proeutectoid substance, the first portions separating have a maximum influence as nuclei on the accumulation of subsequently born material. It follows that the crystals of ferrite copy the form and disposition of the axes of the primary austenite, and there results that called "structure of large crystals" by Belaiew. In hyper-eutectoid steels cementite forms at the periphery of primary dendrites, *mutatis mutandis.*

B. Cooling slow, and undisturbed mechanically.

a. Carbon less than 0.35 per cent. The action is analogous to 2,*A*, just above, precipitated iron adapting itself readily, automatically, to the globular form of ferrite crystals, characteristic of slowly cooled, soft steels. In the final structure there can simultaneously appear the two characteristic forms of ferrite, separating in two phases. (Fig. 16.)

b. Hypo-eutectoid steels with an average composition of more than 0.35 per cent carbon. With low-carbon nuclei, germs of β iron may form, and crystallization is then completed by direct formation of α iron. However, if the average carbon is higher, crystallization of the excess constituent may initiate itself direct as α iron along the axes of primary austenite crystals. The characteristic development of α iron in elongated forms when the process is slow and uninfluenced by previous centers of crystallization operates so that ferrite develops into a spatial meshwork usual in steels containing from 0.40 to 0.75 per cent carbon when cooled after manufacture. (Fig. 17.) In other words, the plate-like habit of α iron is suppressed by the influence of low-carbon axial nuclei if moderate time is given for migration of the crystallites. But if cooling is somewhat more rapid or the piece is hot-worked the germinal influence is interfered with and plate-like laminations appear alongside the meshes.

It may be noted that the structures described immediately above in 2,*B,a* and 2,*B,b* may both appear in the same piece should the difference in carbon concentration in the original austenite crystals be such that it is considerably less than 0.40 per cent at the axes, and as much more at the peripheries.

c. In hyper-eutectoid steels cementite separates as a rule at the high-carbon peripheries, crystallizing in deep-seated interiors only in case temperature drop is too rapid to allow sufficient migration.[5]

C. Slow cooling, with mechanical work. The disturbance is essentially shown by the elimination of the characteristic action of excess-constituent nuclei formed during solidification from the melt. Consequently theory and practice agree that the final metal contains the same structural elements as if slowly cooled without working, but they are independent of each other. (Figs. 13, 14 and 15.)

D. Rapid cooling, with mechanical work. This operates same as *C* immediately above, but each crystalline element is of smaller dimensions so that the two fundamental formations are distinguished with difficulty.

Conclusion

Hypo-eutectoid steels, especially, can therefore be classified and their structure explained by the hypothesis that β iron assumes a granular and α iron a laminar habit. Belaiew's observations also conform rather better than to his own explanation. Thus, his idea that ferrite is ejected to the periphery of homogeneous austenite on very slow cooling is not confirmed by study of a really uniform metal, which then actually gives Widmanstättian structure. His metal was probably somewhat non-uniform, and the reticular network resulting therefrom is better explained by case 2,*B,b*. This of course does not exclude the hypothesis that the peculiar Widmanstättian orientation should be closely related to the octahedral form of austenite, nor to derived elements like martensite. Furthermore Belaiew's remark that undercooling is partially responsible for Widmanstättian structure in slowly cooled steels is not justified by the steel plate I have examined. Here such structure is formed nearby nuclei in low-carbon regions, and under absolutely the same heat treatment, even forming a continuation of the nuclei themselves.

Observations on Catalyzers in Paint and Varnish Manufacture*

By F. P. Ingalls

CATALYZERS are useful industrially not only to bring about chemical reactions which otherwise would not occur but also to accelerate some which otherwise would be too slow. It is this second phase of the subject that is of special interest in the manufacture of paints and varnishes and concerns directly those highly important compounds known as "driers."

Without attempting to discuss the various kinds of paint or varnish, it is a general fact that when ready for application, whether it be by brushing, dipping or spraying, they are essentially liquid in form, although the consistency may vary considerably. This allows of easy application and is highly desirable, but by far more important is the facility with which they become solid after application and by simple exposure to the air are thus transformed into valuable protective coatings.

In paints this solidification, commonly known as "drying," takes place in the vehicle, and while the pigments may exercise a profound influence on the properties of the finished paint, there is no good evidence that the pigments themselves undergo any material change during the process. In varnishes, of course, the question of pigment does not enter.

This drying ensues from oxidation of the oil, accompanied usually, but not always, by evaporation of the volatile "thinner" which may be present, but only the oxidation of the oil is of interest to us at this time.

The liquids capable of oxidation and suitable for our requirements are few and occur among those substances designated as oils. Many oils absorb oxygen from the air by direct exposure, but only a few are transformed thereby into the kind of solid substance desired. Of these few, linseed oil is of paramount importance, and since its behavior with driers is so typical of all the others and consideration of them would take much time, we shall confine our remarks to the action of driers on this oil almost exclusively.

When linseed oil is exposed to the air it absorbs oxygen, increases in weight and volume, passes through a stage of highly increased viscosity and finally becomes a solid, tough, rubbery mass. The rapidity of this oxidation, perhaps indeed even its extent, is dependent upon a number of conditions, chief among which are the temperature and extent of surface exposed, especially the latter. Exposed in layers 0.001 to 0.003 in. in thickness, on glass plates, at a uniform temperature of 75 deg. F., it requires from about six to fifteen days (according to thickness of layer, quality and kind of oil) for the film to become "dry to touch," and in ordinary parlance is then said to be "dry," although it is very well and generally known that the film continues to harden progressively for a very long and indefinite time thereafter. Obviously, this reaction is very slow.

Action of Pigments on Oil Drying

If various pigment colors be incorporated with the oil by a process of mechanical grinding, and the mixture so obtained be spread out in thin layers as above, we observe some very remarkable differences in the drying time. Some pigments, as for instance umber, will shorten it to less than 24 hr., while others will lengthen it into weeks, as in the case of carbon blacks; and certain of the aniline-color tannate lakes (made from magenta or methyl violet) may inhibit the oxidation of the oil to such an extent that even after months of exposure there remains only a sticky, gummy film in nowise acceptable as a good paint coating.

This quickening effect of umber has long been known; just how long is a matter of some doubt, but certainly for two or three hundred years. White lead, one of the most ancient of pigments, has also long been recognized as an accelerator of this drying process; but without attempting to follow the historical development, we may come down to the early half of the nineteenth century when good "boiled oil" and "oil varnishes" which dry in 24 hr. or less had become commercial commodities.

Boiled Oil Oxidation Theory

Because the best of these were prepared by heating the oil with metallic oxides, notably litharge and red lead, and because the oil was still further oxidized by the air during the heating process, there became prevalent a theory that the normal drying time was shortened by virtue of the fact that the oil so treated was already well oxidized and only a limited exposure was necessary to complete the process. This theory, although not now tenable, contained an element of truth, in that coatings with such oils gave harder films than most others made at that time and was further supported by numerous instances where oil which had merely been heated rather strongly in the air showed greatly increased drying power. Without direct knowledge of how this heating was done, nor under what circumstances, we may now assert quite positively that the increased drying power was due to some other circumstance than mere heat and the attendant air oxidation.

In 1867 Mulder undertook to explain the drying of oils, especially linseed, not only by itself but in conjunction with a number of substances introduced as driers.[1]

Little information or new facts were adduced until Hulb's classic research on the halogen absorption of the drying oils, and while his work was of immense value in the analytical identification and valuation of oils, it did not elucidate greatly the action of driers.

Unsaturated Fatty Acids

It had long been known that oils and fats were glycerol ethers (as they were then called, now esters) of fatty acids, and that these fatty acids were in many cases "unsaturated." This was shown by Chevreul, and his work was available to Mulder, but it was as late as 1890 that Hazura succeeded in identifying at least four unsaturated acids in linseed oil and first clearly brought to light the three fundamental substances upon which the drying power is based, and these acids he called linolic, linolenic and isolinolenic. Prior to this time these acids, together with oleic, which is the fourth, had

*A paper read at the New York Section meeting, Jan. 9, and published by permission of the American Chemical Society.

[1]After several series of experiments carefully conducted (and considerable conjecture which doesn't sound so very wild even today), he leaves the question open in the following words quoted directly from his book which we have before us:

"Worin besteht das Trocknen, das Festwerden? Liegt es in den Oelen allein oder auch in Beimischungen? Was wird nach dem Trocknen erzeugt?

"Ich glaube nicht, dass Jemand es weiss, denn ich habe bis jetzt nirgends eine Antwort auf die Fragen gefunden. Man spricht von Bleiseifen in Bleifarben, aber ist diese Bezeichnung wahr?"

["In what consists the drying, the solidifying? Is it due to the oil only or also to the admixtures? What takes place after drying?

"I do not think anybody knows, as I have been unable to find anywhere an answer to the question. We speak about lead-soaps in lead paints; is this designation correct?"]

been obtained often in the saponification of linseed oil, but all together, and in the absence of any good method of separation they had been bunched together under the name of "linoleic" acid. Even today, because there is no commercially available method of separation and since we get good commercial results without direct separation, this nomenclature is still retained, as we shall see a little later.

This last discovery makes it easy to understand why the more or less scientific development of driers should date from this time, and although this rapid historical sketch lays claim to no sort of completeness, or even rigid accuracy in all detail, it serves, nevertheless, to throw much light on the nature and source of these catalyzers or driers which are our chief topic.

Drying Phenomenon Dependent on Certain Metals

What, then, are these catalyzers or driers? In a word, they are certain metallic salts of one or more of the unsaturated acids which characterize the drying oils. There are several metals which, when so combined, are more or less active, but cobalt, manganese and lead are so superior to all others that they are in a class by themselves. Copper and iron may yield driers of no mean order, but are less active than those named, as well as less desirable in other ways, and are never used commercially except under very special conditions. All others are negligible so far as known at present.

Based on the weight of metal present, cobalt and manganese are much more active than lead, but atom for atom the difference is not so great. Between cobalt and manganese there is comparatively no great difference, and until very recent times, when cobalt became cheap, it was never used commercially, although its activity as a drier was known and had been definitely established as early as 1892 to our certain knowledge.

It is fortunate, however, that we have all three, for the technical results obtained by their use show differences, aside from the mere question of activity, that are quite important, and as a matter of fact, the slower lead holds the position of chief importance, although it is rarely used alone, but more generally in conjunction with either manganese or cobalt and occasionally both.

Mulder showed very conclusively that the activity of umber was due, not at all to the ferric oxide, silicon and silicates, of which it was more than four-fifths composed, but to the manganese oxide, which constituted less than one-fifth. He also showed that with both oxides of lead (litharge and red lead) the full effect was obtained only by heating them in the oil and that only a small quantity (a few per cent by weight) was necessary to achieve this result. When oil is so treated the oxides disappear at a rate largely dependent on the temperature and the fineness of the oxide, and although on subsequent standing a noticeable precipitate falls to the bottom, there is no free oxide either in the precipitate or suspended in the oil; but if the clear oil is analyzed, most of the lead is found there, in soluble form, and the oil will dry in hours where it required days before. What has occurred is readily understood. The oil has been partially hydrolized; the freed acids have united with the lead; those lead salts which are insoluble in the remaining oil have settled out; and the soluble ones are dissolved. It is these soluble lead soaps which accelerate the oxidation. This view is substantiated by a number of significant facts.

If oil be heated with almost any of the normal salts of either lead or manganese, acceleration is observed only with those salts which are readily broken down or dissociated at the temperature used. Wherever the metal is too firmly bound to be at least partially dissociated under the conditions of heating there is little or no acceleration. The sulphates, nitrates, chlorides, etc., are of no value as driers, but the acetates and borates are good driers, especially the borate of manganese, which, however, requires a rather high heat to yield its maximum effect. It might be expected that a substance such as lead tri-ethyl would be a good drier. It is a clear, nearly water white, mobile liquid, containing about 70 per cent of lead and freely soluble in linseed oil. We have a small sample for inspection. It is useless as a drier in the cold, and if it must be heated to decomposition, litharge is cheaper. Finally, if the oil be hydrolized with caustic alkali and the resultant soap made into other soaps by the addition of water-soluble salts of lead, manganese or cobalt, fatty acid salts may be made which contain nearly if not quite the theoretical proportion of metal, and when these are dissolved in plain raw oil the accelerating effect is unsurpassed by any other means. These are the so-called "linoleates" of lead, manganese and cobalt, although we have seen that there are at least four unsaturated acids present, to say nothing of the small proportion of saturated acids which are also present in linseed oil. Linoleic acid as an individual is not recognized here except commercially. Many other "linoleates" have been tried, as for instance cerium, of which we have a small sample for inspection, but practically all are inactive. Cerium and vanadium, however, are powerful catalysts in the oxidation of aniline by sodium chlorate.

Some little further investigation is necessary to show which of these aggregated metallic salts are the most active. The saturated salts are essentially insoluble, form no appreciable part of the finished oil, and may be disregarded. The unsaturated acids are difficult of separation either by themselves or in their salts. We can get oleic acid, however, quite readily and in pure form. When the oleates of lead, manganese and cobalt are used as driers, they have indeed considerable power, but they are not so active as the "linoleates" nor do they remain quite so readily in solution. This leads to the conviction that the salts of the $C_nH_{2n-4}O_2$ and $C_nH_{2n-6}O^2$ acids furnish most of the drying power, but it is not yet clearly proved to what extent these differ in activity from each other.

Drier Metal Linoleates

We have already seen that these linoleates are readily formed when the oil is directly heated with a small quantity of the oxides. If the proportion of oxide is increased, more linoleate is formed, and this may be carried virtually to the theoretical limit, though in practice it is seldom done. Linoleates made in this way are highly oxidized during the process. Although the surface exposed is relatively small, the oxidation is rapid because of the presence of the metallic soap and the high heat (300 to 500 deg. F.) and especially when red lead and manganese dioxide are used. Consequently also they are very dark colored. If the cooking is not too long continued, there results an almost black molasses-candy-like mass which dissolves quite freely in turpentine, and is the basis of the so-called japans or japan driers. They are fully as powerful as the "pre-

cipitated" linoleates and have been in use for a much longer time. Special kinds for many purposes contain added resins of one sort or another, but so far as we know the catalytic power is not increased thereby, although in technical practice the intelligent selection of drier is a matter of high importance.

We see from this that these soaps of the unsaturated acids do not have to remain unsaturated to retain their power. They may at least be quite highly oxidized, and this brings us to the consideration of some other compounds of the same metals with organic acids having little or no obvious relation to those discussed. The first of these are the "resinates"; in other words, those made from common rosin.

Precipitated Resinates

If rosin be dissolved in dilute alkali and precipitated with soluble metallic salts from aqueous solution, we get the "precipitated resinates." If the oxides be heated directly with rosin, we get "fused resinates," and these are also frequently made by melting the precipitated resinates with an excess of rosin. They are driers of good power and quite extensively used. A discussion of their relative merits is out of place here and there are differences of opinion concerning their actual value.

China Wood Oil

Finally, we have the soaps derived from tung oil (china wood oil). Used from time immemorial in China for waterproofing purposes, it has been used in this country only since very recent times. It dries even more rapidly than linseed, but in a very peculiar way which precludes its direct use in paints or varnishes. The film has the appearance of frosted glass, and looks as if some soluble substance had crystallized out, but as a matter of fact the appearance is due to a multitude of very fine wrinkles and is a case of excessive "crimp." It is a very valuable oil, however, and has almost revolutionized the varnish industry because of its very hard film. The acids are unsaturated to about the same extent as those from linseed, as is shown by the iodine number, but in other respects are widely different. Lead, manganese and cobalt soaps of them, however, show similar catalytic activity. In fact, aside from purely technical considerations, we may use the linoleates, tungates and resinates almost indiscriminately either alone or with each other in any kind of drying oil, without noticeable inhibition of individual activity.

Speed of Drying

Concerning the quantity of these driers required to produce the maximum acceleration, much depends on conditions. Unless the metal is in solution or retained in what may be termed the active field, it has little or no power. Whether the solution is crystalloidal, partly colloidal or wholly colloidal is open to discussion, but when a precipitate forms it is (at least relatively) inactive, even though it may retain considerable metal.

Roughly speaking, it is easy to bring the drying time down to 7 or 8 hr. for linseed oil, but to go below this time requires extraordinary drier. With lead alone it is difficult to reach this speed with any amount within reason. With manganese three to five parts in 10,000 will suffice. Cobalt requires about the same, perhaps slightly less. These figures indicate the actual metal in the active field as shown by analysis of the *clear oil*, and may be widely different from the amounts put in when preparing it. The films must be less than 0.002 in. thick and the temperature about 75 deg. F.

It is difficult to establish definite limits of this sort on account of the many variable factors.

Choice of Drier

In conclusion, it is perhaps desirable to say a few words bearing on the technical choice of drier for different uses. It has been noted that lead is slower than manganese or cobalt, but its influence on the character of the film is very favorable. This was noted by Mulder, and he describes it by saying it is "tough, like rubber," while manganese gives a film "tough, like leather." At any rate the film is rounder and fuller, does not expand so much and therefore does not wrinkle up so decidedly in forming, where it happens to be a little too thick. This is known as "crimping." Manganese, on the other hand, dries faster, expands more, gives a coat that looks thin or skimpy, and has a decided tendency to crimp. In general, cobalt films are similar to manganese films. In all cases, however, much depends upon how they are incorporated into the oil.

Both manganese and cobalt impart a darker color to the oil than lead, but on account of their greater activity may be used in much smaller quantity and the difference largely overcome in this way. Further, if the quantity of metal is small, the oil will bleach out on drying; nevertheless in the presence of turpentine high color is liable to develop.

In general practice, therefore, it is customary to use lead for character, and jack it up with manganese or cobalt for speed. A good strong-drying oil will generally show on analysis, in parts per 10,000: lead, 50 to 150, and manganese 5 to 15. When cobalt is found, the quantity is usually smaller than the manganese unless used in its place, in which case the quantity required is approximately the same. It is claimed that cobalt will give a lighter colored oil than manganese for the same speed; this may be true, but much depends upon the method of production.

Whether these substances are true catalysts acting by their mere presence, or whether they depend on a rapid vibratory alternate oxidation and reduction may be elucidated at some future time, but we are certainly fortunate in having them at our disposal in the present.

Sag Paste for Burns

During the war large quantities of sag paste were purchased by the Government, principally for the treatment of gas burns. The paste was prepared by a large number of manufacturers according to the following formulæ:

FORMULA 66

	Parts by Wt.
Zinc oxide, 100 mesh, U. S. P.	40
Benzoinated lard	20
Refined raw linseed oil	20
Adeps lanae, U. S. P.	20
Coloring matter	1

FORMULA 146

	Parts by Wt.
Zinc oxide, 100 mesh, U. S. P.	45
Benzoinated lard	10
Raw refined linseed oil	30
Adeps lanae, U. S. P.	15

FORMULA XII-A

	Per Cent
Soya bean oil	62
Zinc stearate	38

This paste was put up in collapsible metal tubes in several sizes.

Commercial Development of Fused Silica

An Account of the Development of the Electrothermal Processes of Fusing Glass Sand—Reactions Between Carbon and Silica and Application of Gas Phases to Process—Properties of Product Physically Explained

By JOHN SCHARL* and WALLACE SAVAGE

WHILE fused silica has attracted the attention of many scientists[1] for the past eighty years, it has been within the latter part of the last twenty that it has had any large technical application. This was due primarily to the lack of demand rather than knowledge of methods of fusing. As early as 1849, eighteen years before the invention of the dynamo, Despretz fused silica by passing the current from 600 bunsen cells through a small carbon rod[2] embedded in sand. He obtained a very hard tube with six times the diameter of the original electrode. This tube probably consisted of a core of the various products of reaction between carbon and silica within a mass of fused sand. In 1886 E. H. and A. C. Cowles[3] experimented with fused sand in their well-known granular resistor-type electric furnace. They took out patents on the carbon reduction products obtained from the silica, but did not recognize their composition or application until 1896, when E. G. Acheson[4] put commercial carborundum on exhibition at the World's Fair at Chicago. Immediately after this, the chemistry of the reaction products involved was studied and found to be represented by the following equations and equilibriums:

$$SiO_2 + C = CO + SiO \quad (1)$$

$$SiO + C = SiCO \leftrightharpoons CO + Si \quad (2)$$

$$Si + C \leftrightharpoons SiC \quad (3)$$

In reaction 1, the silicon monoxide is a gas which upon cooling condenses directly into an extremely light powder weighing only 40 oz. to the cubic foot and known in commerce as monox. In reactions 2 and 3 the silicon is in the gaseous state and condenses to the liquid before solidifying. The products produced in the third reaction depend entirely upon the temperature used. Around 1,600 deg. C. amorphous carborundum is said to be produced; above 1,850 deg., the melting point of silica at pressures where the liquid phase exists, carborundum crystals form; and in the environs of 2,240 deg., the reaction goes to the left, producing graphite and silicon gas.

Fused Rock Crystal Ware

In 1901 Shenstone[5] developed a process for making fused silica ware with the oxy-hydrogen flame. He heated Brazilian rock crystal quartz to 1,000 deg. C. and quenched it in cold water, thus breaking up the silica at the points of temperature strain. These pieces, as they did not tend to shatter after this treatment, were fused into pellets by means of the 2,000-deg. oxy-hydrogen flame, and were then drawn into fine rods. The fused silica rods, reheated and in the softened state, were wound on a platinum rod. By this means the operator was able to build up a fused silica tube which could be blown into any form desired without calling for greater skill than has been exhibited by glass blowers for the past 3,500 years.

Almost simultaneously, Heraeus[6] worked out the problem of obtaining molten silica in a form suitable for blowing. He fused rock crystal directly on iridium and later zirconia, with the oxy-hydrogen flame and then applied the usual glass-forming processes.

The ware made from rock crystal is very transparent and is mostly used in thermometer stems and ultra-violet ray tubes, due to its low expansion and non-absorption of short-wave light.

Peculiar Phenomena of Fused Silica

When the crystalline forms of silica are heated, they expand 781 $\times$ 10^{-8} per deg. C. per unit of length on the main axis and 1419 $\times$ 10^{-8} in the cross-section, thus setting up a considerable as well as uneven strain, when suddenly cooled through a large temperature range. If the heating is carried on slowly enough, crystobalite crystals will be formed which at higher temperature will invert to tridymite.

At about 1,400 deg. C. the small content of impurities, which exist in amounts of about 0.2 per cent in the purest silica commercially obtainable, will begin to show signs of weak fluxing activity and the mass will begin to cohere, even though the temperature is at least 450 deg. below the theoretical melting point of pure silica. As the temperature increases, the mass grows more and more viscid until a temperature of about 1,750 deg. is reached, when it begins to sublime. In this, the highest state of fusion obtainable at atmospheric pressure, the thermal expansion of the silica will be about 17 per cent of the original volume of crystal solids. After rapid cooling to atmospheric temperature, the thermal contraction in volume will be found to be only about 0.07 per cent. This remarkable property of a solid maintaining almost the fusion volume throughout so great a temperature range without exhibiting any tension strains is scientifically unexplainable as well as unique with this product. According to Henning and Randall, the coefficient of expansion for fused silica at 200 deg. is 518 $\times$ 10^{-9}; at 900 deg., 538 $\times$ 10^{-9}; and at 1,100 deg., 583 $\times$ 10^{-9}, which indicates that a rod one meter long with a temperature change of 1,000 deg. C. or 1,800 F. will be expanded

*Superintendent Fused Silica Works, General Ceramics Co.

[1] Gaudin succeeded in fusing small beads with a blow pipe and drawing them in 1839. He observed that it was optically inactive. (*Comp. Rend.*, vol. 8, pp. 678, 711.) Gautier produced capillary tubes of it in 1869, which he exhibited in Paris in 1878. (*Comp. Rend.*, vol. 130, p. 816.) Boys obtained fine cords of it by drawing fused beads out by means of an arrow suddenly released from a bow. They were so small in diameter that it was necessary to use a magnifying glass to find them. The cords were used in suspending mirrors in galvanometers, etc. [Eng. Pat. (1889) 4,849.]

upon heating or contracted upon cooling only slightly over one-half millimeter.

Care has to be exerted not to maintain fused silica for long periods at temperatures between 1,150 and 1,400 deg. C., which is its range of devitrification. In all probability this phenomenon is the formation of tridymite crystals and the segregation of the various impurities previously mentioned. The resulting devitrified product is weak mechanically. It expands and contracts like ordinary quartz from fifteen to thirty times as much as fused silica, and if, after heating, it is quenched in cold water, it cracks. The rate of devitrification is very low at 1,150 deg., but increases rapidly toward 1,400 deg. Usually this phenomenon can be counteracted by heating to white heat, temperatures above 1,400 deg. C., and rapidly cooling below 1,150 deg., where it is permanently stable, though well out of its normal slow-cooling crystalline phase. Doubtlessly, the phenomena here exhibited justify the application of the theory of solid solution developed in connection with high flux content glasses to fused silica. In this case the silica should be considered the solvent and the impurities the solutes, which in their amounts and effects on the fusion temperatures are analogous to carbon and the like in steels. The chemistry of the phenomenon of solid solution probably will find no better opportunity for development than is exhibited here, and knowledge of fundamental importance to the science of ceramics should be derived at the same time.

Electrothermal Processes Developed

Immediately after the value of fused silica had become generally known by means of the laboratory ware produced by Shenstone in England and Heraeus in Germany, several technical men undertook to develop a more economical product. Glass-makers' sand was

FIG. 1. DRAWING TUBE ON CHANNEL IRON BENCH

employed in the place of rock crystal, and the electric-resistance furnace instead of the oxy-hydrogen flame. In 1902 Dr. R. S. Hutton[7] reported his investigations of fusing sand, which he found to be most successfully accomplished by means of embedding a graphite rod in sand and heating with a current of high amperage. The fused silica did not apparently react with or adhere to the hot electrode, due to the formation of intervening gases. These undoubtedly consisted of vaporized silica, which, in turn, being in contact with the hot graphite electrode, formed the various carbo-silica reaction gases previously discussed in connection with carborundum. A white opaque tube was obtained, due to the fact that the silica could not be heated to the liquid state and the gas cells originating from the interstices of the sand were locked in similarly to the leavening gases in dough. They were of microscopic size, however, and gave the product a beautiful satin white finish. Day, Shephard and Mehner believed that liquid silica could be produced by fusing the sand under pressure, and a transparent product free from gas inclusions obtained. Their experimental work was not carried to a successful conclusion, though their idea was fundamentally sound. However, what the lowest vapor pressure of liquid silica actually is, and what pressure

FIG. 2. TYPES OF LABORATORY WARE

of silica gas is in equilibrium with the fluid silica of sufficiently low viscosity to release automatically these imprisoned gas cells, are both unknown bits of scientific information.

Development of Commercial Production

Although Hutton had obtained a molten tube of silica which could have been manipulated by most any skilled glass blower in producing all varieties of fused silica ware, no blowing was attempted, even though Shenstone had published a description of his process of blowing fused rock crystal tubes the year before. Elihu Thompson[8] took out the first patent on forming fused sand, in which he claimed the use of shaped electrodes in producing hollow silica ware.

In 1904 Dr. James Francis Bottomley,[9] Sir Arthur Paget and Dr. Robert Salmon Hutton, by applying vitrifacturing engineering, were able to devise a process for obtaining a ware from fused sand, which they produced at Wallsend-on-Tyne, England, under the firm name of Thermal Syndicate, Ltd., and trade named and marked Vitreosil.

In Germany, Ludwig Bolle & Co. for a time acted as distributors for the fused silica products of the Thermal Syndicate, and through this connection Dr. August Voelker, a partner of Bolle, became interested in the industry. In 1907 he took out a series of patents[10] on the basis of which the Deutsche Quarzglas Gesellschaft commenced the production of Sidio Fused Silica. In 1911 the Cölner Fabrik für feuer und säuerefestes Glas took over the Voelker patents and Sidio works and started operating.

Recently the Deutsch - Englische Quarzchmelze-Pankow, Berlin, using the patents of the Thermal

Syndicate, absorbed the interests of the Cölner Fabrik, thereby combining the two processes. In France, fused silica products are manufactured by Le Quartz Fondu, which manufactures in accordance with the process of Dr. August Voelker.

The United States is the only large industrial country that has in the past decade been extensively supplied by imported fused silica products. These materials have found large and important applications in many fundamental industries. Because it has become undesirable as well as inconvenient to remain dependent on imported supplies entirely, the General Ceramics Co. has taken up their manufacture and erected a well-equipped plant in connection with its Chemical Stoneware Works at Keasbey, N. J. The company is thus prepared to build every part that goes into high-grade

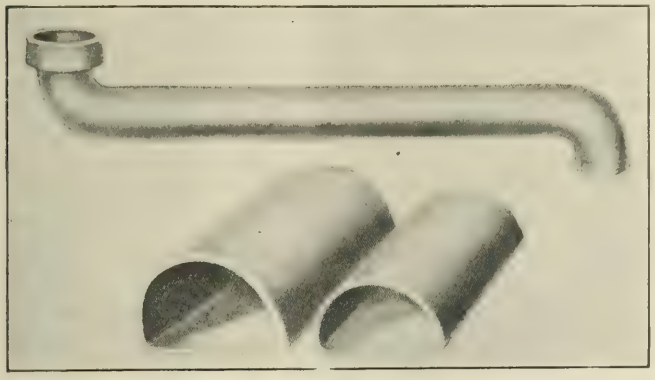

FIG. 3. MUFFLES AND CONDENSER PIPES

acid-plant installations, in the stoneware portions of which it has experienced marked success.

Previously to beginning operations on fused silica, about a year was spent in perfecting the equipment. The electric furnaces used are of extremely simple design, consisting of no more than an inch Acheson graphite rod about 3½ ft. long embedded in the highest grade glass sand obtainable. As soon as the patent applications have been allowed, the details of both the methods of fusing and blowing will be published. In making tubes, the fused tubular mass is drawn out to the length which gives the desired diameter and then laid on a flat runway of channel iron to straighten before cooling. (Fig. 1.) Iron molds of similar construction to those used in making bottles are used in forming all the usual types of blown ware from the hot stock. In these latter operations, the usual procedure of the modern glass-blowing art is followed. Views of some of the various types of products produced are shown in Figs. 2 and 3. The rough blown ware is finished by grinding with carborundum wheels and air blasts.

Semi-Translucent Fused Silica

If opaque fused silica is quickly heated a second time to over 1,800 deg. C. with either an oxy-hydrogen flame or an electric arc, the cellular structure collapses, giving a semi-translucent product. The hot gases originally occupying these minute cells undoubtedly consisted of a mixture of air and silica vapor. Upon cooling, the silica condensed to the solid state, leaving the air in the cells in a very rarefied state. These voids amount to approximately 6 per cent of the volume of the opaque fused silica. Upon sudden heating and softening, the walls seem to collapse before the silica has time to produce sufficient gas pressure to support them in equilibrium with the external atmospheric air pressure. Fig. 4 illustrates a two-phase Rennerfelt arc furnace in operation producing semi-transparent ware. This ware is a better conductor of heat, is stronger, has greater resistance to abrasion and therefore is more easily kept constant in weight than the first fused opaque ware.

Important Properties of Fused Silica

As every one must appreciate, the most valuable property of fused silica is its resistance to temperature shocks, which, in combination with the fact that it is acid-proof,[11] abraded with difficulty and the only vitreous material that is absolutely insoluble in water, makes it almost as estimable as platinum in both the laboratory and the plant. Combustion tubes of it can be heated to temperatures as high as 1,100 deg. C. at pressures of four atmospheres or *in vacuo* without causing difficulties. At the highest heats the stoppers in the ends of these combustion tubes are transformed to neither charred cork nor fused rubber, due to the low longitudinal heat conductivity at moderate temperatures of this material, which is composed of an accumulation of millions of minute rarefied gas cells. In this property, these cells have certainly contributed a very valuable service to scientific work of a far-reaching nature.

Fused silica is an ideal electrical insulator as well as a permanent one, because it contains no decomposition products, such as soda or potash, which tend to

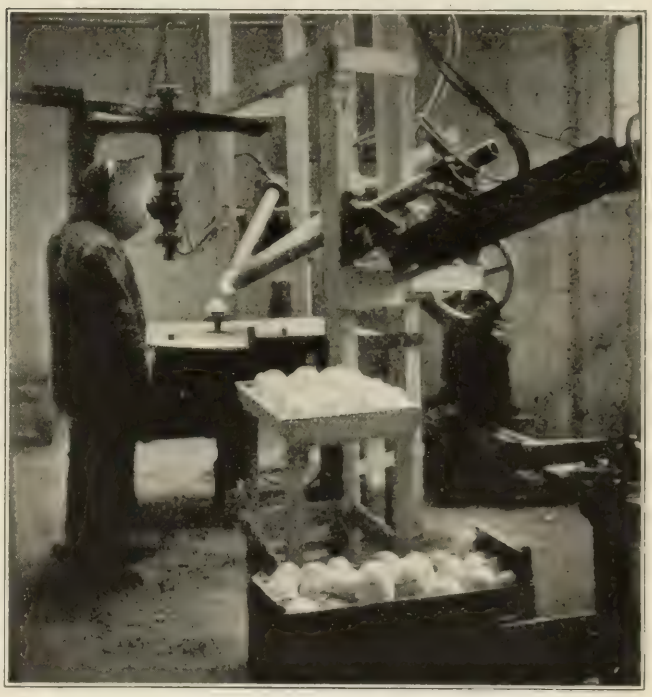

FIG. 4. REFUSION PROCESS FOR PRODUCING SEMI-TRANSPARENT WARE

collect moisture and form solutions of electrolytes on its surface. Its refractory properties stand it in good stead for high-temperature insulation. At the present time, an experimental investigation is being made on methods of producing spark plug insulators of it economically enough to compete with porcelain. It is believed there will be less trouble experienced with short circuits from cracks formed by thermal shocks in the case of fused silica.

[11] Hydrofluoric acid reacts with it, forming SiF_4, H_2SiF_6; and phosphoric acid and other fluxes attack it at temperatures above 400 deg. C.

The Electric Furnace Reduction of Garnet

By M. deKay Thompson and John Davenport
(Analytical Work by Max Knobel)

A SERIES of experiments were made with the object of determining whether the silicon and iron present in abrasive garnet could be removed as ferrosilicon and a slag or aluminous residue produced which would contain a higher percentage of alumina than the original garnet. This residue, on account of its higher percentage of alumina and hardness, should possess good abrasive qualities when used against low-tensile-strength metallic materials. The alloy produced would, of course, have value as ferrosilicon.

Material and Apparatus

The garnet used was from the mine of the United Mineral Co. at South Danbury, N. H. This garnet is the regular red abrasive garnet used in coating paper to make abrasive garnet paper, and it has the following chemical composition:

	Per Cent		Per Cent
Silica	35.0	Calcium oxide	1.3
Alumina	27.0	Magnesium oxide	2.2

Remainder iron oxide.

The garnet grains used were about $\frac{1}{16}$ in. in diameter. Ordinary coke with 10 per cent ash was the reducing agent. The furnace consisted of a square firebrick shaft 18 in. outside diameter and 9 in. inside by 16 in. deep, built up on a piece of boiler-plate. The bottom of the shaft was filled with granular carbon to a depth of about 6 in., and a graphite plate was placed on top of this. In order to give good electrical contact between the boiler-plate and carbon, nine iron rods 2 in. long and driven into the boiler-plate projected upward into the carbon. The bricks were held in place by angle irons and the cracks were filled from the outside with fireclay. A carbon-tar mixture was also used in making tight the bottom where necessary. The tap-hole was formed by means of an iron rod and tap-hole fireclay, as is done in copper blast-furnace settlers. The furnace had a firebrick cover. The boiler-plate formed one electrode, and a 2-in. graphite rod, suspended vertically in the center of the furnace shaft, was the other. A 150-kw. transformer, with voltage regulation in steps of ten volts, served as a source of power.

Method of Operation

The method of operating was to start the arc by means of a small piece of carbon placed between the movable, vertical electrode and the graphite furnace bottom. The charge was then fed in as desired. During operation a bright silicon flame, together with a blue carbon monoxide flame, was given off, and there was considerable volatilization, during a run.

It was difficult to get both the alloy and the slag into solution for analysis. Each was fused in a nickel crucible with a one-to-one mixture of sodium carbonate and sodium peroxide. The nickel crucibles were rapidly destroyed.

Results

The results, as shown in the accompanying table, were encouraging. It will be seen from runs 8 and 10 that the alumina in the slag was about 62 per cent, or the concentration was more than twice that in the original garnet. The ferrosilicon contained 24 per cent to 26 per cent silicon and from 5 per cent to 10 per cent aluminum. It will be noted that all of the iron was removed from the slag and about half of the silicon. A 27 per cent excess of coke (No. 3) gave as complete reduction as 37 per cent excess coke. The addition of sawdust did not make a product which differed in appearance from that made with coke alone. These results were encouraging enough to have this reduction tried on a larger scale.

No.	Duration in Min.	Kw.	Kg. of Garnet	Kg. of Coke	Excess Coke Above Theoretical to Reduce All Fe and Si	Kg. of Alloy Produced	Analysis of Alloy, Per Cent	Kg. of Slag Produced	Analysis of Slag, Per Cent	Per Cent of Garnet Made Into Alloy	Per Cent of Garnet Made Into Slag

Remarks:

Run No.
3 1 in. of slag fused solid at bottom; above, several inches of porous material.
4 Fraction of inch of fused slag at bottom, with several inches of porous material above.
5 Charge had 1.5 kg. sawdust. Alloy did not run together.
6 Charge had 1 kg. sawdust.
8 Furnace lined with graphite plates.
10 Furnace 13.5 x 13.5 in. to remove brick walls from heating zone.

The work was therefore carried on at the General Electric plant at Schenectady, N. Y., where even better results were obtained due to the large-scale operation.

It is probable that more silicon could have been removed if the garnet and coke had been ground to a fine powder, well mixed and briquetted with tar as a binder, but this has not yet been tried.

Massachusetts Institute of Technology,
Cambridge, Mass.

Ferromanganese Not Covered by War Minerals Relief Act

The Attorney General of the United States has handed down an opinion to the effect that producers of ferromanganese are not entitled to reimbursement under the War Minerals Relief act, for losses incurred in its manufacture. The opinion was rendered at the request of the Secretary of the Interior in connection with the claim of the Anaconda Copper Mining Co. for $561,346.62 for losses sustained in producing and in preparing to produce ferromanganese. "The claim of the Anaconda company," says the Attorney General, "evidently is based upon the contention that ferromanganese is an intermediate metallurgical product of manganese and is embraced within the provision for payment of losses to producers by reason of the specific mention of intermediate metallurgical products in the act of Oct. 5, 1918, and the adoption of the minerals enumerated in that act in the first paragraph of section 5 of the act of March 2, 1919. There is, however, no basis for this contention, as the intermediate metallurgical products, metals, alloys and chemical compounds covered by the act are all specifically named in the act of Oct. 5, and as there is no reference to ferromanganese, the rule of law *expressio unius exclusio alterius* applies."

How the British Chemists Are Organizing

A Study in Professional Politics and Economic Conditions—British Industry Must Recognize the Importance and Value of the Chemist—Labor Party and Policy Not Attractive to English Chemists

By FREDERICK E. HAMER
Editor, *Chemical Age* (London)

ONE may confidently begin by saying that before the war chemistry, of all the English professions, was the least organized for its own protection and the least appreciated from the national point of view. That undesirable condition has since been substantially modified and improved by two influences. The extent to which military operations in the final stage of the war became dependent on the applications of chemical science has forced upon the public a new sense of the immanence of chemical science throughout practically all industrial processes. On the other side, the ever-rising cost of living, the progressive advances of salary secured by manual workers, and the contrast of their own lot with that of less educated and less responsible classes, have created among working chemists a new sense of class consciousness, and forced upon them the conclusion that relatively to the cost of their education, the responsibility of their work and the vital part that work plays in national industry, their economic condition compares very unfavorably with that of equally or even less educated workers.

Chemists Discuss Problems of Organization

Hitherto the English works chemist has held a sort of half-way position between capital and manual labor. He is not in active opposition or alliance with either interest; nor yet is he sufficiently organized to constitute a definite party to industry himself. Considered as a professional man, he lacks the close and powerful corporate organization which enables the legal and medical professions to safeguard their professional rights and especially to keep out the "quack"; considered as a workman, he hesitates to descend to the trade union basis, and to join with the manual workers whom he directs for the protection of their common interests as employees. So, in a word, the working chemist, economically, hangs suspended halfway between heaven and earth, and he is beginning to look for some more solid and comfortable resting place. Everywhere one turns today chemists are discussing problems of organization. They feel keenly the need and the justice of improved status and improved pay, but so far their views as to how these ends are to be attained are hazy and even conflicting. It may be interesting, therefore, especially in view of the new labor problems arising in the United States, to set out broadly the position as it exists in England today.

To begin with, it should be understood that the English chemist's demand for improved conditions is no piece of mere trade union tactics. The feeling is common to the university chair and the smallest works laboratory. It is based on the conviction that the science of chemistry and all who practice it deserve fuller and more generous recognition all around.

Prof. Henry Louis of the Armstrong College, Newcastle, put the point to me quite frankly some time ago —that when ambitious and capable young men came to him inquiring about chemistry as a profession for life he often felt obliged to warn them of the poor return they might get. John Gray, a managing director of the great firm of Lever Bros., who this year succeeded Prof. Louis as president of the Society of Chemical Industry, told me with equal candor that if we wanted the best chemical brains for the service of industry employers must be more prepared than many are at present to recognize the commercial value of the chemists.

To these testimonies may be added that of Richard B. Pilcher, who has just completed twenty-five years as secretary and twenty as registrar of the Institute of Chemistry. The Institute is essentially a professional and academical body, with powers under its charter to hold examinations and confer degrees. There can be no suspicion of trade unionism about it. yet even the Institute is so much concerned about the economic status of its members that it recently issued a questionnaire on the subject of salaries and working conditions. The results have just been tabulated by Mr. Pilcher, and are shown in the accompanying table.

WORKING CONDITIONS OF BRITISH CHEMISTS

	Average Salaries, Including Bonus					
Age	Industry	Assistants to Private Practitioners	Government Service	Municipal Service (Whole-time)	Teaching	Average
21–24	£268	. . .	£256		£184	£250
25–29	345	. . .	327	£284	270	328
30–34	435	£289	346	290	291	390
35–39	546	. . .	447	360	421	499
40–44	606	484	503	440	400	523
45–49	712	400	545	653	481	592
50–54	883	275	1,290	775	653	789
55–59	609	. . .	586	531	766	571
60 and over	610	. . .	840		888	747

This table is based on 927 individual returns. As the chemists making the returns are all members of the Institute, it may be assumed that they are all of good academical standing, and that the figures are substantially higher than those that apply to the whole body of works chemists. In addition to the comparatively poor financial pay, the chemist has often to work long overtime without extra remuneration, his annual holiday is usually only a fortnight, and he is generally subject, owing to the confidential nature of his duties, to close restrictive covenants.

In addition to the Institute there are two other bodies organized for the special protection of chemists' interests. The National Association of Industrial Chemists is registered as an ordinary trade union, but it deliberately holds aloof from the political Labor party. The British Association of Chemists, though not for-

mally registered as a trade union, professes similar aims, but here also there is a strong objection to merging the interests of chemists in the Labor movement.

Thus, it will be seen, there are in England three separate bodies all claiming to protect the professional rights of the chemist and all founded on different principles. Among the three there is a certain amount of confusion of thought, and just now the problem is how to find some central organization as wide as chemical industry itself which shall become the recognized custodian of the whole profession. One of the most definite suggestions is that there should be a National Register of Chemists, equivalent to the roll of the Law Society or the Register of Teachers, and that steps should be taken either by charter or act of Parliament to prevent any not admissible to the Register from practicing or accepting appointments as a qualified chemist.

The "Black-Coats" (Professional) Class

Quite recently a new and interesting factor has emerged in the shape of a bid from the political Labor party for a compact with the professional class of workers, or "Black-Coats" as they are called. It is no secret that the English Labor party is out to form a Labor Government. Its political power has been growing for some time, but the more intelligent leaders now recognize that manual labor, of which the English Labor party is made up, cannot carry the country unless it has with it the brain workers too.

Recently a conference was held in London with the object of "capturing" the brainworkers for Labor, and the National Association of Industrial Chemists and the British Association of Chemists were invited to join. Both attended, but both declined to merge their identity with the Labor party. For the moment there is no doubt that this represents the general attitude of the British chemical profession. The problem, then, for the future is whether English chemists with other professional bodies will be strong enough to form for themselves what is called a "third party," strong enough to take the necessary action for the protection of their own interests, or whether economic pressure will drive them, as it has driven the National Union of Journalists and other bodies, to throw in their lot unreservedly with the general Labor party.

For the moment, however, strong as the demand among working chemists is for improved economic conditions, there is an equally strong objection to adopting some of the leading doctrines of organized labor. In the first place, in spite of the suave assurances of the more educated labor leaders, labor is essentially and as many fear increasingly a class movement. It refuses to recognize that prosperous national industry is the combined result of co-operative effort and organization. It selfishly assumes that industry and profit are as assured as tomorrow's sunrise, and all that labor has to do is to get as much out of it as possible, while putting as little into it as may be. The Whitley Councils, which have been formed for the joint development by employer and employed of British industry, have already degenerated into cockpits for debates over wages and shorter hours, and instead of developing the co-operative spirit have in many cases merely accentuated the conflict between capital and labor.

Another common fallacy is that labor, by which is meant mere manual labor, produces all the wealth of the country. The part which the capitalist, the organizer, the inventor, the chemical and the civil engineer, and last of all the patient research worker who may at any moment revolutionize existing processes of production by some new discovery—all these count for nothing in the estimate of labor. And it is easy to understand why men who live by their minds' work refuse to subscribe to such a wooden and unimaginative theory of industry.

Another point in labor policy which is viewed with grave suspicion is the Prussianizing of labor. One of the popular cries of a few years ago was the right of every man to work. Now no man must be allowed to work unless he is in the union, and in one particular union which happens for the time being to be the most powerful, and there is a ruthless insistence on the division and subdivision of labor into endless little water-tight compartments, each of which is an exclusive preserve. The effect of the application of this principle to chemical and scientific work generally is delightfully satirized by a well-known consulting chemist, Ivor James:

"The organic chemist would have to cease thinking inorganically; the analyst would not soar researchwise; the professor would surrender his consulting practice, and the lecturer his private tuition; Carius tubes would be the perquisite of the glassworker's union; to tighten or loosen the bolts of an autoclave an engineer —in common parlance, a fitter—would be present, accompanied by his invariable shadow, the mate, bearing a spanner; electro-analysis or electro-reduction would necessitate an electrician—of what variety we do not know, but certainly he would have to be there; and if by chance the unfortunate chemist happened to wash his apparatus, the laboratory steward would complain to the bottlewasher's union, and monsieur would be reprimanded with an intimation that the incident was anathema and must not occur again. The position would be ridiculous, but the ridicule would be just."

Chemists Shun Intellectual Bondage

But perhaps what the intellectual worker most objects to in modern labor is what is known as the "ca'-canny" policy. In practice this means that the bricklayer, whatever his capacity, must not lay more than a certain number of bricks an hour; that the compositor must not set more than a certain number of lines; that the barber must not shave more than the prescribed number of customers, and so on all through industry. This is bad enough applied to the purely mechanical trades, for it cuts down the producing capacity of the best artisan to the pace of the slowest and least efficient, and kills the honest workman's personal zest in his work. It is waste of time for the apprentice to attend technical classes and master the art or science of his craft if when he becomes a full-grown workman his union encases him in the iron fetters of a standardized output. But applied to science, to research, to every form of intellectual work, it is a deliberate sterilizing of potential brain power, a suppression of personal initiative, a bondage of all the forces of thought and energy that make for human progress.

Little wonder, then, that English chemists, eager as they are to see an improvement in their conditions and prospects, decline open eyed to enter into such an intellectual bondage, and prefer to work out their own salvation on more liberal and humane lines. That is the problem to which they are now addressing themselves, and developments of great interest may be expected in the next few years.

Aluminum Rolling-Mill Practice—III Ingot Heating and Mill Calculations

Specifications and Some of the Uses for Sheet Aluminum Are Noted, Followed by a Discussion of Furnaces for Heating Ingots Preparatory to Slabbing — Tables and Examples of Calculations Are Given Whereby Individual Orders May Be Rolled With Minimum Allowance for Scrap*

BY ROBERT J. ANDERSON AND MARSHALL B. ANDERSON

MANY applications of aluminum sheet have been made, and uses for the metal in this form have increased rapidly in recent years. Aluminum and 1.5 per cent manganese-aluminum alloy sheets are used very largely in motor-car body construction, while substantially pure aluminum in the form of sheets finds considerable employment for fabricating cooking utensils, for building vats and vessels, for aircraft parts, and for various small stampings. Sheet aluminum is also fabricated for motor-car headlights, surgeons' splints, artificial limbs, and soldiers' canteens and field utensils; while in the form of rolled and annealed sheets, the metal is used in printing and lithography. Many other uses are on record, but the main outlet for the metal in sheet form is for motor cars, cooking utensils, vats and tanks, and for small stampings.

In addition to substantially pure aluminum, some of its light alloys, notably duralumin, are rolled into sheets for purposes where greater strength is required than can be obtained with the metal itself. Some of the rolled and annealed light alloys have as great ultimate strength as hard-rolled pure aluminum. The progress made with regard to rolled light alloys of aluminum was marked in connection with the late war, and this will result in further applications of the metal. An alloy containing about 1.5 per cent manganese, whose production has already been described in the early part of this article, is also rolled for so-called hard sheets, and it is employed considerably in motor-car body construction.

Very little scientific work has been performed in the rolling of aluminum, nor is much information available with regard to the rolling of its light alloys for the manufacture of sheets. Some information in connection with rolling rods in the light alloys is on record. The corrosion of aluminum sheets and cooking utensils, as well as of some of the rolled alloys, including duralumin, has been investigated at considerable length, and a fair amount of data is on hand in regard to that matter.

SPECIFICATIONS FOR SHEET

As to specifications for sheet aluminum, few are available. Specifications for substantially pure aluminum sheet, both cold rolled and annealed, and for duralumin are given in Tables VI and VII. Three of these specifications are in condensed form of the complete specifications of the Bureau of Aircraft Production, while the fourth is a provisional specification of the British Admiralty Air Department; new specifications are now being prepared by the Bureau (now the Engineering Division, Aircraft Service), and those given in the tables may be superseded by others in the future. Specifications for sheet aluminum, particularly for deep drawing stock, have never been worked out satisfactorily, to the writers' knowledge. In the case of deep drawing stock, tensile tests and hardness values are practically useless criteria in attempting to determine the "drawability" of a sheet. The only test

TABLE VI. SPECIFICATIONS FOR ALUMINUM SHEET

Bureau of Aircraft Production Specification for Soft Annealed Sheet Aluminum

The following grades of aluminum, conforming to the requirements of the specification for ingot aluminum, may be ordered to this specification:

Grade	Al, per Cent Min.
Standard No. 1	99.0
Standard No. 2	98.0

Test specimens cut in any direction from sheets must have the following physical properties:

American Wire Gage, B. & S. Nos.	Thickness In.	Thickness Mm.	Minimum Tensile Strength Lb. per Sq. In.	Minimum Tensile Strength Kg. per Sq. Cm.	Elongation in 2 In., per Cent (Min.)
10 to 16, incl.	0.102 to 0.051	2.59 to 1.30	12,000	844	30.0
18 to 22, incl.	0.040 to 0.025	1.02 to 0.64	12,000	844	20.0
24 to 26, incl.	0.020 to 0.016	0.51 to 0.41	12,000	844	10.0

Specification for Hard-Rolled Sheet Aluminum

The grades of aluminum may be ordered as above.

Test specimens cut in any direction from sheets must have the following physical properties:

American Wire Gage, B. & S. Nos.	Thickness In.	Thickness Mm.	Minimum Tensile Strength Lb. per Sq.In.	Minimum Tensile Strength Kg. per Sq.Cm.	Elongation in 2 In., per Cent (Min.)
10 to 26, incl.	0.102 to 0.016	2.59 to 0.41	22,000	1,547	2.0

TABLE VII. SPECIFICATION FOR DURALUMIN SHEET

Bureau of Aircraft Production Specification for Aluminum-Alloy Sheet

Sheet under this specification shall have a maximum specific gravity of 2.85 and shall be made from Standard No. 1 aluminum ingot.

Test specimens cut in any direction from the sheets must have the following physical properties:

Temper No. 1	
Tensile strength (min.), lb. per sq.in.	55,000
Kg. per sq.cm.	3,866
Yield point (min.), lb. per sq.in.	25,000
Kg. per sq.cm.	1,758
Elongation (min.) in 2 in., per cent	15
Temper No. 2	
Tensile strength (min.), lb. per sq.in.	50,000
Kg. per sq.cm.	3,515
Yield point (min.), lb. per sq.in.	25,000
Kg. per sq.cm.	1,758
Elongation (min.) in 2 in., per cent	20

British Admiralty Air Department Specification for Duralumin Sheets

The sheets are to be made of duralumin alloy of specific gravity not exceeding 2.85.

Strips cut from the sheets lengthwise are to show when tested in tension not less than—

Thickness of Sheets	Tensile Strength Tons per Sq.In.	Tensile Strength Kg. per Sq.Cm.	Elongation, per Cent on 2 In.
0.05 in. (1.27 mm.) and above	25	3,515	15
Below 0.05 in. (1.27 mm.)	25	3,515	10

*For Parts I and II see CHEM. & MET. ENG., vol. 22, Nos. 11 and 12, March 17 and 24, 1920, pp. 489 and 545.

[8]Anderson, Robert J., "Erichsen Tests on Aluminum Sheet," *Iron Age*, vol. 101, 1918, pp. 950-951; "The Testing of Sheet Aluminum," *Iron Age*, vol. 102, 1918, pp. 148-149.

which can give any definite indication of how sheets will perform in the draw press is the cupping test (Erichsen). This test is of great value for the purpose mentioned and can be rapidly applied. The writers are not aware that this test has been insisted upon to any extent as yet for deep drawing stock, but users of sheet for this purpose will do well to investigate its merits.

Heating Ingots for Rolling

The statement has already been made that aluminum ingots are either rolled directly from the molds after solidification or they are preheated to a definite temperature in ingot-heating furnaces before rolling. We will deal first with the preheating of ingots for rolling.

In order to bring ingots to the desired rolling temperature, they are charged into an ingot-heating furnace and raised to about 425 to 450 deg. C. Rolling temperatures may vary in different works, and may be higher or lower in case light alloys are rolled. The ingot-heating furnace may be either gas- or oil-fired, or it may be heated electrically. A typical furnace is a gas-fired, five-track furnace. In case gas is used for firing, it is advisable to have oil-burning equipment provided, and *vice versa.*

The tracks in an ingot-heating furnace may be made of two ordinary steel rails placed about 1 ft. apart and fastened to the furnace floor. Ingots are pushed from the charging end to the front of the furnace by an ingot pusher, consisting of a ram, with a slow rate of motion, actuated by motor drive. To charge an empty furnace, an ingot is placed upon one of the tracks at the rear of the furnace, the ingot pusher is brought into position, and the ram then pushes the ingot along the track and toward the front of the furnace. In the present case, the ram does not travel far, i.e., it cannot push an ingot from the charging end to the discharge end, but it has an effective working distance of up to 24 in. (0.6 m.) or thereabouts. Hence, tracks are filled by pushing forward a number of ingots together.

Ingot-heating furnaces may be built in various sizes, but a typical furnace will have inside measurements as follows: 35 ft. long, 10 ft. wide, and 4 ft. high (10.7 x 3 x 1.2 m.). Double doors are hung on pulleys with balance weights at each end of the furnace and temperatures are taken by means of three pyrometers placed through the roof. An average furnace, with five tracks holding thirty-three ingots 12 in. (30 cm.) wide, contains 165 ingots when filled.

Heating Ingots Two-High

Attempts have been made to double the capacity of such a furnace by charging ingots two-high, but this is a questionable practice unless the furnace has been expressly designed for that purpose, since heating two-high in an improperly designed furnace leads to higher scrap losses at the hot mill and introduces other difficulties. In some furnaces, when running ingots two-high, it is necessary to overheat the top rows of ingots in order to raise the bottom rows to the rolling temperature. Aluminum becomes increasingly hot short at higher temperatures, and this leads to breakage of ingots, particularly on the first pass. Overheated ingots, i.e., those rolled at too high temperatures, usually result in "fire-cracked" slabs. Furthermore, the higher temperatures of the ingots cause higher roll temperatures, and this results in more roll breakages. Two-high heating of ingots will usually result in non-uniformity of ingot, and consequently of rolling temperatures, which is to be strictly guarded against. If the metal is rolled too hot it is too "tender"; if rolled too cold, it takes too long to break the ingots down. Rolling temperatures in relation to the amount of reduction have not been worked out, but 425 to 450 deg. C. at the furnace is fairly satisfactory for most breakdown operations.

When a track is full, and the hot mill is running, an ingot will be withdrawn from the front of the furnace for rolling; the track will be kept full of ingots by immediately placing a cold ingot on the track at the charging end and pushing up the line of ingots. In actual operation, the ingot-heating furnace is continually kept full of ingots by charging a cold ingot after withdrawing a hot one for rolling. Ingots are withdrawn from the various tracks in rotation so that each remains in the furnace for about the same length of time. Thus, in a five-track furnace, which may hold thirty-three 12-in. ingots per track, the usual method is to push out and roll the thirty-three hot ingots from track 1, filling up with cold ingots as rolling proceeds. Ingots are then rolled from track 2, then from track 3, and so on. By the time the ingots on track 5 have been rolled, those on track 1 are at the rolling temperature. Thus the operation proceeds continuously except in case of breakdown or shutdown at the hot mill. Breakdowns of the ingot-heating furnace itself are rare, since there is practically nothing which can get out of order. The only difficulties at the furnace will come in connection with the fuel supply and the method of firing. When a cold furnace is started, it may require, with gas or oil firing, from 10 to 12 hr. to raise the ingots to the rolling temperature. After the first batch has been rolled, succeeding charges will be in the furnace for about 6 hr.

Furnaces have double doors at both ends, and it is imperative to keep the doors shut at all times except when necessary to charge or withdraw ingots; otherwise, the ingots in the furnace may be unduly cooled by draughts. This is an important point in cold weather if the mill building is not tight. In a five-track furnace with double doors, it is necessary to open both doors at either end when withdrawing or charging ingots on the middle track. A better design would consist of a six-track furnace so arranged that each door would serve three tracks.

When an ingot is to be broken down in the hot mill for the production of slabs, it is withdrawn from the furnace at a temperature of 425 to 450 deg. C., and immediately conveyed on a truck to the mill and rolled. From 30 sec. to 2 min. may elapse prior to the first pass, the elapsed time depending upon the distance from the furnace to the mill and also upon the behavior of the previously rolled ingot. Thus, the hot-mill roller may consider the metal to be too hot, and he will accordingly hold the ingot so as to allow it to cool somewhat before rolling. This appears to be a matter which varies with individual rollers; it may have some bearing upon practical hot-mill operation, but, on the other hand, it may be based upon the vagaries of different rollers.

Breaking Down Without Preheating

In the foregoing, the statement has been made that aluminum ingots are also rolled without preheating in a furnace, by sending them to the hot mill directly from the molds. In this practice about 5 min. are

allowed for cooling to the desired rolling temperature. It is a mistake to roll aluminum in this way. The most self-evident reasons which should deter mill superintendents from so rolling aluminum are these: (1) There is no temperature control; (2) the temperatures are usually unknown; (3) there are wide variations in the temperatures of succeeding ingots; and (4) if a breakdown occurs at the hot mill, production is stopped not only there but at the melting end. Moreover, there is a distinctly greater percentage of defective slabs produced at the hot mill when rolling directly from the molds than when ingots are preheated to a definite temperature. Actual temperature measurements of ingots rolled directly from the molds have been taken at the hot mill, and variations from 370 to 625 deg. C. have been observed. Such variations are altogether too wide. At the lower temperatures, it takes too long to break down an ingot because more passes must be given, as the metal is not so readily worked at lower temperatures. At the higher temperatures the metal is hot short and breaks readily under pressure.

TABLE VIII. THICKNESSES TO WHICH INGOTS ARE BROKEN DOWN HOT FOR VARIOUS SIZES AND GAGES OF ALUMINUM SHEETS

Finished Gage to Be	Finished Width to Be, In	Finished Length to Be, In.	Should Be Broken Down Hot to, In. Thick	Remarks
1 to 4	...	.....	0.500	Finished from the hot mill slab
5 to 7	...	.....	0.300	Finished from the hot mill slab
8 to 9	...	.....	0.250	Finished from the hot mill slab
10 to 11	.....	.....	0.200	Finished from the hot mill slab
12 to 13	...	.....	0.300	Slabbed cold
14	40	124	0.300	Slabbed cold
14	41 to 70	125 to 160	0.400	Slabbed cold
15	.....	.....	0.250	Slabbed cold
16	40	100	0.250	Slabbed cold
16	48	124	0.300	Slabbed cold
16	60	160	0.400	Slabbed cold
17 to 25	.....	.....	0.250	Slabbed cold
26 to 40	.....	.....	0.200	Slabbed cold

(1 in. = 2.54 cm.)

..... indicate practically any length or width.

In general, the hot-mill slabs are cold-slabbed to one-half the original thickness. Gages from 1 to 11, inclusive, are not slabbed.

Table XI gives relation between gages and thickness.

Rolling temperatures are important, and it is a difficult matter to maintain anything like uniformity of temperature in succeeding ingots where they are rolled directly from the molds. In case of emergency, say where a breakdown takes place at the ingot-heating furnace, or there is a gas shortage or difficulty with oil circulation, it might be desirable to roll ingots directly from the molds and thus avoid entirely tieing up production on the hot-mill. But, in general, this method is never the best for hot-mill practice.

Calculations for Sheets

Reasonably exact calculations are required in determining the size and number of ingots to be rolled for a given order of sheets. Sheet orders may be given in different ways; for example, the customer may specify a certain number of sheets of definite gage and size, or, on the other hand, a certain number of pounds of sheets. Orders may, therefore, read as follows: 100 sheets, 16-gage, 40 by 96 in.; or 1,000 lb. of sheets, 18-gage, 44 by 112 in. Sizes in demand vary widely according to market requirements.

Tables VIII, IX, X, XI, XII, XIII and XIV will be found useful in calculating sheet orders. Table VIII gives the thicknesses to which ingots are broken down hot for sheets of various gages and sizes; the figures

TABLE IX. THICKNESSES TO WHICH HOT-MILL SLABS ARE COLD-SLABBED FOR VARIOUS GAGES AND SIZES OF ALUMINUM SHEETS

Finished Gage To Be	Finished Width to Be, In.	Finished Length to Be, In.	Should Be Cold Slabbed to, In	Remarks
1 to 11	...	.....	Not slabbed	Finished from the hot-mill slab
12 to 13	...	.....	0.150	Roughed
14	...	50 to 124	0.150	Roughed
14	...	130 to 164	0.200	Roughed
16	...	110 to 124	0.150	Roughed
16	...	134 to 164	0.200	Roughed
17 to 25	...	.....	0.125	Roughed
26 to 40	...	.....	0.095	Roughed

(1 in. = 2.54 cm.)

... indicate practically any length or width.

Table XI gives relation between gages and thickness.

TABLE X. SCRAP ALLOWANCES FOR FINISH SHEARING ON ALUMINUM SHEETS

Finished Gage to Be	Allowance for Side Shearing, In.	Allowance for End Shearing, In
7 and heavier	2.0	6.0 to 7.0
8 to 10	2.0	8.0 to 10.0
11 to 13	2.0	11.0 to 13.0
14 to 18	2.0	14.0 to 18.0
19 to 20	4.0	19.0 to 20.0
21 to 23	5.0	21.0 to 23.0
24 to 26	6.0	24.0 to 26.0
27 to 30	7.0	27.0 to 30.0

(1 in. = 2.54 cm.)

The figures given include both sides and both ends: for example, in the case of a 16-gage sheet, 1 in. is allowed for shearing on each side, and 8 in. on each end.

Larger end and side scrap allowances are made for the lighter gages, because of the greater tendency of these gages to crack during rolling.

Table XI gives relation between gages and thickness.

TABLE XI. WEIGHTS OF ALUMINUM SHEETS AND SLABS IN VARIOUS GAGES AND THICKNESSES

Sheet Gage, A.W.G.	Thickness In.	Thickness Mm.	Wt., Lb. per Sq.Ft.	Kg. per Sq.M.

Notes to Table:

1. Thickness to which ingots are broken down hot for various sizes and gages of sheets are given in Table VIII.
2. Thickness to which hot-mill slabs are cold slabbed are given in Table IX.
3. Relation between gage and thickness in Table XI.

1 in. = 2.54 cm.

The area of any slab at the thickness indicated is the product of the length times the width.
This table is used in conjunction with Table XII.
1 in. = 2.54 cm.

indicate the ordinary sizes in the gages mentioned, but the other possible variations are many indeed. The figures are applicable to ingots of any size; the size of ingot chosen will depend upon the finished dimensions of the sheets, and such ingots will be rolled as will permit of small scrap losses on shearing. Table IX shows the thicknesses to which hot-mill slabs are cold-slabbed before roughing for various gages and sizes of sheets. Table X gives the usual scrap allowances for finish shearing on aluminum sheets. Figures for shearing must be available so as to calculate the sizes of the hot-mill slabs. Table XI gives figures for the weight per sq.ft. and the thickness of various gages in aluminum sheets and in different thicknesses of slabs. Table XII is a scale for cuts on hot-mill slabs; the tabular quantities are the length which should be cut from a slab in order to roll to a definite length in the finished sheet. Table XII is to be used in conjunction with Table XIII; the latter gives the lengths and widths possible in hot-mill slabs rolled from 4 x 12 x 17 in. (13 x 30 x 43 cm.) ingots to various thicknesses. Table XIV shows the approximate number of sheets to be rolled per pack for various gages; lengths and widths do not determine the number of sheets to be rolled in pack, as will be explained at length in later paragraphs. The use of these tables will be explained at length with practical examples.

With the exceptions given below, all ingots broken down in the hot mill are subsequently cold slabbed to 0.125 in. (3.8 mm.) thick before roughing and finishing. The exceptions are these:

(1) Sheets to finish heavier than 12-gage and any length are not slabbed, but are hot rolled to thicknesses as follows:

Finished Gage	Hot Rolled to
1 to 4	0.500 inch (12.7 mm.)
5 to 7	0.300 inch (7.6 mm.)
8 to 9	0.250 inch (6.4 mm.)
10 to 11	0.200 inch (5.1 mm.)

(2) Sheets to finish 12- and 13-gage and any length are slabbed to 0.150 in. (3.8 mm.).

(3) Sheets to finish 14-gage and 50 to 124 in. (1.3 to 3.1 m.) long are slabbed to 0.150 in. (3.8 mm.).

(4) Sheets to finish 14-gage and 130 to 164 in. (3.3 to 4.2 m.) long are slabbed to 0.200 in. (5.1 mm.).

(5) Sheets to finish 16-gage and 110 to 124 in. (2.8 to 3.1 m.) long are slabbed to 0.150 in. (3.8 mm.).

(6) Sheets to finish 16-gage and 134 to 164 in. (3.4 to 4.2 m.) long are slabbed to 0.200 in. (5.1 mm.).

(7) Sheets to finish 26-gage to 40-gage, inclusive, and any length are slabbed to 0.095 in. (2.4 mm.).

Usually, all sheets to finish lighter than 11-gage are hot-rolled to twice the cold slab thickness; that is, the hot slab should be of such thickness that it may be reduced one-half on cold slabbing and still leave sufficient thickness for roughing and finishing. The figures given in the foregoing and in the tables are largely applicable in a general way, but other combinations may be as suitable. The use of the tables in connection with calculations and the actual methods of calculating orders may conveniently be explained by means of a few examples.

Example 1.—Suppose an order for 500 lb. of 20-gage, 30 x 40 in. dead soft sheet comes into the mill. On 20-gage, sheets of this size will be run two in a pack. The scrap allowances for shearing are 4 in. for side scrap and 20 in. for end scrap, from Table X. In breaking down 4 x 12 x 17 ingots for 20-gage sheet, the ingots will be hot rolled to ¼ in., and then cold slabbed to ⅛ in. (Tables VIII and XII and above explanation). The thickness of 20-gage sheet is taken as 0.031 in. The calculations are:

0.125 ÷ 0.031 = 4, a factor.
60 in. = finished length plus scrap allowance.
60 ÷ 4 = 15, the length of cuts to be made on the slab.
150 in. = length of a 4 x 12 x 17 in. ingot after breaking down to a thickness of 0.125 and a width of 34 in. (Table XIII.)
150 ÷ 15 = 10, the number of pieces which can be cut from a cold slab, rolled as indicated.
30 x 40 in. is the size of sheets wanted.
30 x 40 = 1,200 sq.in., or 12,000 sq.in. of 20-gage sheet can be obtained from one 4 x 12 x 17 in. ingot.
12,000 ÷ 144 = 83 sq.ft. of sheet.
20-gage sheet weighs 0.445 lb. per sq.ft.
0.445 × 83 = 38 lb. of finished sheet from one ingot.
Figuring 10 per cent of total order for scrap, then 500 + 50 = 550 lb.
550 ÷ 38 = 14+ ingots.
Then, 15 ingots, 4 x 12 x 17 in., should be run for this order.

Example 2.—Consider an order for 500 lb. of 20-gage, 7.5-in. diameter circles, strip-roll metal. This order will be rolled from 4 x 12 x 17 in. ingots. It would be impractical to attempt to roll a hot-mill slab to a width of about 7.5 in. from such ingots, and therefore it will be advisable to roll to about twice this width. The circle shearing allowance on a 7.5-in. circle will be 1 in. Hence,

7.5 + 1 = 8.5 in.
8.5 × 2 = 17 in.
Add 1 in. for slab shearing.
17 + 1 = 18 in., the width to which the hot-mill slabs should be rolled.
Metal for 20-gage strip rolled sheet will be hot rolled to 0.375.
0.375 ÷ 0.031 = 12, a factor.
100 in. = length obtained from a 4 x 12 x 17 in. ingot after breaking down to a thickness of 0.375 in. and a width of 18 in. (Table XIII).
The order calls for 7.5-in. diameter circles.
$\pi r^2 = \pi \times 3.75^2 = 44.18$ sq.in.
100 × 12 = 1,200.
1,200 ÷ 8.5 = 141, the number of circles in half the width of a slab.
141 × 2 = 282, the number of circles which can be obtained from one ingot.
44.18 × 282 = 12,458.8 sq.in. of circles from one ingot.
12,458.8 ÷ 144 = 86.5 sq.ft. of circles.
20-gage sheet weighs 0.445 lb. per sq.ft.
0.445 × 86.5 = 48.5 lb. of circles from one ingot.
Figuring 10 per cent of total order for scrap, then 500 + 50 = 550 lb.
550 ÷ 48.5 = 11+ ingots.
Then, 12 ingots, 4 x 12 x 17 in., should be run for this order.

Example 3—This example will explain in detail the use of Tables XII and XIII in calculations for sheets. Consider an order calling for 1,000 lb. 16-gage, 40 x 144 in., intermediate sheets, to scleroscope 13 (regular hammer). The thickness of 16-gage is 0.0508 in. Scrap allowances on sheets of the size mentioned will be 2 in. for side scrap and 16 in. for end scrap. Hot-mill slabs for these sheets will be rolled to 0.300 and cold slabbed to 0.150, and the hot slabs should measure 42 x 160 in. The calculations are:

0.150 ÷ 0.0508 = 3, a factor.
160 in. = length of the cold slab.
160 ÷ 3 = 53 in., the length of cuts to be made on the cold slab.
Referring now to Table XIII, and looking in the cold slab thickness column headed 0.150 in., run down the column to 42 (the width of the slab); the number opposite is 106.
106 in. = length obtainable from a 4 x 12 x 17 in. ingot after breaking to 0.150 x 42.
106 ÷ 53 = 2, the number of pieces which can be cut from a cold slab, rolled as indicated.
40 × 144 in. is the size of sheets wanted.
40 × 144 = 5,760 sq.in., or 11,520 sq.in. of 16-gage sheet can be obtained from one 4 x 12 x 17 in. ingot.
11,520 ÷ 144 = 80 sq.ft. of sheet.
16-gage sheet weighs 0.7078 lb. per sq.ft.
0.7078 × 80 = 56.6 lb. of finished sheet from one ingot.
Figuring 10 per cent of total order for scrap, then 1,000 + 100 = 1,100 lb.
1,100 ÷ 56 = 19+ ingots.
20 ingots, 4 x 12 x 17 in., should be run for this order.

Example 4—Later on it will be said that scrap losses may assume unreasonable proportions because of miscalculations with the size ingots to be rolled. As stated previously, the size ingots to be rolled depends upon the size of sheets to be made, and it is desirable to choose such ingots as will give small scrap losses in shearing, i.e., for example, the ingots should cut into several pieces without much scrap. A practical example will demonstrate the principles involved. Suppose an

order for 1,000 lb., 16-gage, 30 x 60 in., hard-rolled sheet is received. The question is: What size ingots shall this order be rolled from? The practical tendency in calculating would be to try a standard ingot, say 4 x 12 x 17, and see how this would work out as to scrap on shearing. The calculations for a 4 x 12 x 17 ingot would be:

0.125 ÷ 0.050 = 2.5, a factor.
The length of the sheet after scrap allowance may be taken as 75 in.
75 ÷ 2.5 = 30 in., the length of cut to be made on the cold slab after cold slabbing.
Referring to Tables XII and XIII, a cold slab run ⅛ in. thick and 32 in. wide would be 160 in. long. 160 ÷ 30 = 5 times and 10 remainder.

Shearing as indicated would allow five pieces but 10 in. scrap.

This is rather high scrap loss, so it will be advisable to try another standard ingot. Such an ingot will be one measuring 4 x 12 x 20 in. The calculations for the size will be:

0.125 ÷ 0.050 = 2.5, a factor.
75 ÷ 2.5 = 30.
The length of a cold slab run ⅛ in. thick and 32 in. wide from a 4 x 12 x 20 in. ingot will be 182 in. (a figure which can be obtained by calculations, and more readily in mill practice by drawing up a table similar to Table XII for ingots of this and other sizes).
182 ÷ 30 = 6 times and 2 remainder.

TABLE XIV. APPROXIMATE NUMBER OF SHEETS FOR VARIOUS GAGES TO BE ROLLED IN PACK

Gage*	Number of Sheets in a Pack	Gage*	Number of Sheets in a Pack
20	2	31	6
21	2	32	6
22	3	33	6
23	3	34	7
24	3	35	7
25	4	36	7
26	4	37	8
27	4	38	8
28	5	39	10
29	5	40	10
30	5		

* See Table XI.

Shearing as indicated would allow 6 pieces to be cut from each slab with only 2 in. of scrap. This is a better figure, and for the order in question, 4 x 12 x 20 in. ingots would be run.

The examples given above show in a general way what calculations arise in aluminum rolling-mill practice, and they indicate short methods for arriving at the desired results. At times, an order may be short of the required weight or number of sheets due to rejections by the inspector, because of wrong shearing, or because of scrapped slabs or sheets at the mills. No calculations can possibly remedy these difficulties. Accordingly, it is advisable to carry a fair sized stock of the sizes most often called for. Moreover, the requirements of the market, while varied, bulk very largely in certain sizes and gages, so that a stock may profitably be carried in order to fill short orders.

(Part IV, dealing with slabbing, will be published in our next issue.)

Picric Acid Plant Sold

The director of sales of the War Department announces that the Ordnance Salvage Board has sold to H. C. Couch, president of the Arkansas Light & Power Co., representing a group of business men of Little Rock, Ark., the acid-manufacturing plant near Little Rock, which was constructed by the Ordnance Department during the war for the production of picric acid. The price obtained by the Government for the property was $770,000. The purchasers were the highest of five bidders who submitted proposals for the property.

Magnesite Tariff Bill

At the hearings before the House Ways and Means Committee on July 16 and 17, 1919, of the magnesite tariff bill (H. R. 5,218), the producers of refractory magnesite were well represented, and the question of the use of magnesite in oxychloride cement received but scant attention. Calcined or caustic magnesite was included in the same classification as dead-burned and grain magnesite and the bill, as passed by the House, calls for a duty of ¾c. per lb.

However, at the hearings before the Senate Committee on Finance on Jan. 13 the composition floor manufacturers had an opportunity to present their objection to the tariff.

Calcined magnesite enters into the manufacture of Sorel cement, sanitary flooring, stucco, interior plasters and pipe insulation; a considerable business in these and other materials containing caustic burned magnesite has been built up in the past twenty years, it being estimated that in excess of 50,000 tons of crude ore was used in 1919, which is about 17 per cent of the total estimated domestic production. The producers represented that their products were in competition with other flooring materials, such as wood and ordinary cement, and that the additional cost which would be imposed should the tariff be granted would prohibit the use of their product. The present price of around $60 a ton for the caustic magnesite and $45 per ton for the chloride was compared with $25 and $16 respectively for the pre-war price and considered as sufficient to develop domestic production.

In addition the quality of the domestic caustic burned magnesite was represented as not being as uniform as that produced from Grecian ores, the principal source of foreign supply, and that because of the unreliable qualities an additional hardship was imposed upon the industry. The suggestion was made that magnesite containing an insufficient amount of iron to produce a satisfactory refractory be excluded from the provisions of the bill.

The use of magnesite in flooring for steel cars and boats, where its plasticity is an important quality, and in offices, hospitals and schools, where the sanitary and quiet features are of value, has been making particular progress during the past few years. A further important use is for exterior stucco, for which there is no practical substitute. This brings out the fact that magnesite is of wide usefulness outside the production of refractories.

German Nitrate Industry

The American Chamber of Commerce in Berlin has recently reported the results of its investigation into the present status of the industry. It appears that the entire production of nitrates in Germany is under the control of the Stickstoff Syndikat, with headquarters at Berlin. Both the Haber and cyanamide methods are used for fixation of nitrogen. The Haber plants are extensive and are located at Merseburg and Ludwigshafen. War-time developments have made Germany entirely independent of Chile, and not only will she supply her own requirements, but proposes to export fixed nitrogen as soon as her own needs are fully covered. Inland prices of nitrate and the various byproducts have been adjusted and are published in the *Reichs-Gesetzblatt*, 1919, No. 218. All questions of export and import are determined by the Stickstoff Syndikat.

Pulverized Lignite Fuel in California

By Roy N. Buell

EARLY in 1918, the hand of the Federal Government had been placed on the utilization of all fuel throughout the entire country, and in California, as elsewhere, the Fuel Administrator, in order to carry the state over a period of excessive need, had organized a corps of fuel engineers and inspectors to see that every possible source of supply was surveyed and that every pound of oil, coal or wood consumed was burned with a maximum of efficiency. The consumption of fuel oil was exceeding production by over 5,000 bbl. per day, and notwithstanding the fact that many non-essential plants had been entirely cut off, the shortage threatened to become more and more acute as time went on, unless some new source of fuel supply could be discovered.

Survey of the Lignite Field

It was decided to make a general state survey of all fuels with a view of finding some practical auxiliary for oil, and among the many possibilities to receive serious attention was California lignite. Large deposits of this material were known to exist in the Priest Valley, in which the Stone Canyon mine is situated; at Corral Hollow, where the Tesla mine is located; near Mount Diablo, at the old Black Diamond mine; in Dos Rios county, which was merely a good prospect, and in Amador county at the Ione coal mine. Experts from the United States Bureau of Mines and the technical staff of the State Fuel Administration were sent to examine these properties and report the possibility of using their output as an immediate source of domestic and commercial fuel.

The report submitted by these engineers was very thorough and complete, but hardly as reassuring in respect to the available fuel supply as had been anticipated. The Stone Canyon mine, while it contained by far the best coal in the state, could not be put in a workable condition for several months, and then at great expense. The Tesla mine, which had been worked many years before to a depth of about 900 ft. at three different levels, was found to be filled with water to within 300 ft. of the top, and aside from this a large amount of money would be required to replace tracks, elevators, tipples, etc., that had previously been either removed or destroyed. Other small deposits around Livermore, in the Mount Diablo district, were either undeveloped or completely worked out.

FIG. 1. INTERIOR OF IONE LIGNITE MINE, IONE, CAL.

In Dos Rios county several test holes were drilled and much preliminary work was accomplished, but no large veins were discovered that would warrant further continuation of the work on a large scale. It was proved, however, that this particular deposit in Dos Rios county was a high grade variety of semi-bituminous coal, equal in B.t.u. content to the Stone Canyon product. Private parties have continued to explore this field and some well-known geologists have ventured their opinion that a large coal deposit will eventually be located.

Ione Mine Chosen

One of the last mines to be explored was that at Ione, and here the engineers found that coal was actually being mined and that the plant was prepared to turn out about 500 tons per day. In the old days, before the advent of fuel oil and the discovery of better coal in Wyoming and Utah, a large portion of the fuel consumed by the locomotives of the Southern Pacific R.R. was obtained from this mine. Many an old locomotive fireman can still be found in California who can tell you many interesting incidents concerning his experience with Ione coal.

After much discussion and careful consideration of the final report submitted by the engineers, the Fuel Administration decided that the lignite from the Ione mine, although of inferior quality, offered the best possibilities for immediate service. The next step was to determine the best method to be pursued in burning the lignite. The consensus of opinion seemed to be that the best efficiency in combustion could be obtained by drying, crushing and afterward burning the lignite in a pulverized state, properly mixed with air.

Advantages of Burning Pulverized Lignite

Among the advantages of burning the lignite in pulverized form, the one that stood out above all others was the fact that no matter how much ash the fuel contained it could be burned with good efficiency. Coal and lignites, having a large ash content, are difficult to burn on grates, owing to the fact that as soon as combustion commences the ash collects all around the carbon and completely shuts off the air. Besides this, the high volatile content of the lignite does not thoroughly mix with the air, so that the combustion of the gases is not complete without admitting a large amount of excess air, and even then the efficiency is poor. When the lignite is pulverized, however, the particles are so fine that approximately the proper amount of air to insure complete combustion surrounds each little atom of fuel, which condition not only guarantees high efficiency in burning but permits of easy and accurate control.

Installation of Experimental Equipment

To carry on the necessary experimental work, preliminary to installing the process in large commercial power plants, it was decided to construct a small demonstration plant in San Francisco. Accordingly, a 50-hp. "Kewanee" return tubular boiler was equipped with the Buell-Santmyer pulverized coal system, which was considered best to burn the California lignite. Ione lignite, containing an average moisture of 40 per cent, as

mined, was allowed to air dry for seven days in shallow tipples at the top of the mine shaft, when it was shipped to San Francisco, in open cars, for treatment.

As received at the plant, the analysis was as follows:

	Per cent As received	Dry Per cent
Moisture	22.44	00.00
Volatile	43.37	54.60
Fixed Carbon	20.41	26.32
Ash	14.78	19.08
	100.00	100.00
B.t.u. per lb.	9,322	12,016

The fuel, as unloaded from the cars, was first crushed to about one-half inch. It was then dried in a semi-direct, artificially fired drier until the moisture content was reduced to approximately 6 per cent. One of the most important operations in the preparation of pulverized lignite is the drying process. At the San Francisco plant about one-sixth of the weight of the raw material was carried off as vaporized moisture, and to accomplish this, 50 lb. of pulverized lignite was consumed as drier fuel to every ton of dried product. The average temperature maintained inside the drier was 250 deg. F.. and great care had to be taken that the heat did not rise above this point, which is apt to cause spontaneous combustion or perhaps explosions.

After the lignite had been dried as described, it was pulverized to about 175 mesh, separated by air and stored in a concrete bunker, ready for use. One of the big bugaboos always brought forward in every argument against the use of pulverized lignite is that it is impossible to keep this material in storage for more than a few days without danger from spontaneous combustion. The writer's experience, however, seems to refute this claim, as he has known of one particular instance in California where several tons of powdered lignite was stored in a *metal* hopper for six months with apparently no ill effects whatsoever.

Operation of Combustion Equipment

The general layout of the combustion equipment used at the San Francisco plant is shown in Fig. 2. The pulverized lignite drops by gravity from the bunker into the feeder, where a screw conveyor, driven by a variable speed electric motor, carries the fuel to the mixer chamber. Between the feeder and mixing chamber is situated a cross, with the upper connection left open, through which induced air may be drawn, aiding materially in stabilizing the pressure. An air compressor of the rotary type furnishes the necessary energy to transport the powdered lignite from the mixer to the combustion chamber, and supplies about 40 per cent of the air required for proper combustion, the other 60 per cent being obtained by induction.

The average air pressure employed at this plant was 3 lb. at the compressor and about 12 oz. at the burner. The powdered lignite, after meeting the compressed air at the mixer, is carried along through a 3-in. pipe to the burner, the most sensitive piece of apparatus in the whole plant, although very simple in construction. The focusing sleeve, on the end of the burner, is so arranged that the flame zone can be lengthened or shortened as desired.

A secondary air line, taken off the main line near the compressor, extends completely through the burner, with orifices near the extreme end looking back toward the front of the boiler, which acts as a brake on the main body of forced air and lignite. In actual combustion, this secondary air brake causes the flame corona within the furnace to expand or contract as desired. A half-inch steam jet was used to deflect the cutting flame away from the under side of the boiler plates.

The burner was lighted instantaneously with a torch through an opening in the boiler front. These openings were also used to allow more secondary air to enter the combustion chamber if required. About 15 per cent excess air was generally employed in combustion, although when the boiler was under peak load, this amount might be slightly increased. No changes worthy of note were made in the settings of the boiler, the object being to demonstrate how readily this system could be adapted to any ordinary boiler at small expense. The grate bars were removed, and later on an inclined fill was placed in front of the bridge wall to reduce back pressure.

To remove and collect the ash a permanent soot blower was installed in the front end of the tubes and an ash trap constructed under the rear end of the boiler, near the cleanout door. A complete set of instruments was installed to record the temperatures of the feed water,

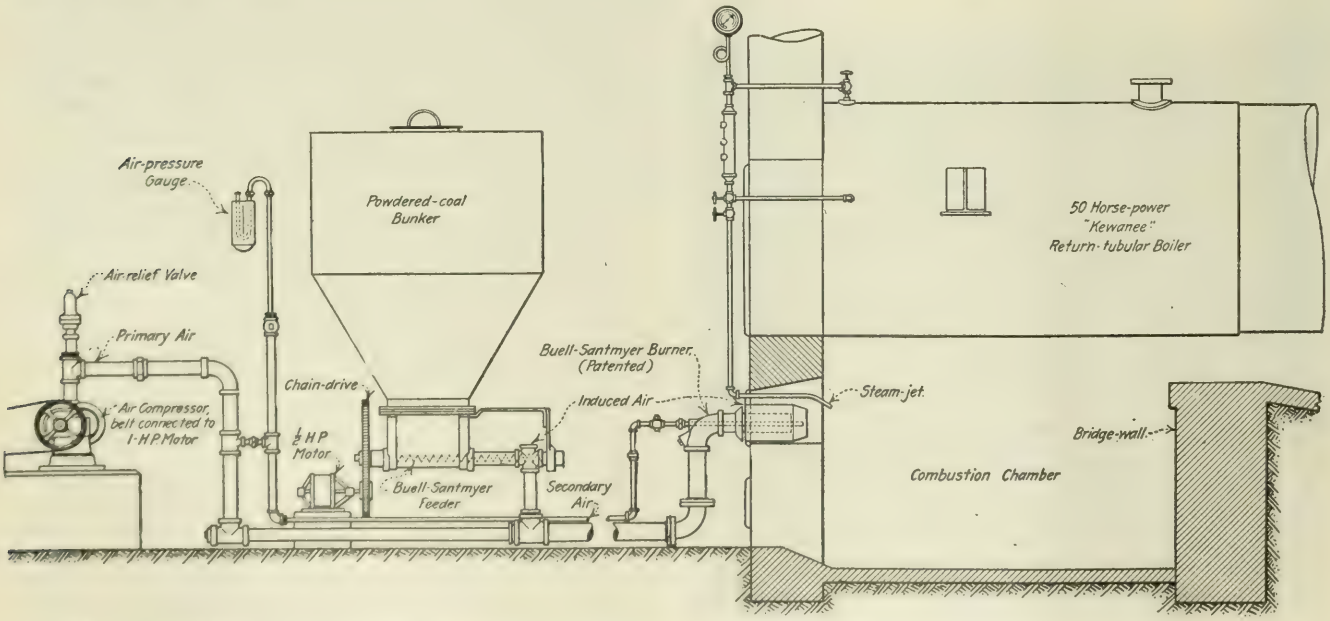

FIG. 2. GENERAL LAYOUT OF COMBUSTION EQUIPMENT, EXPERIMENTAL PLANT, SAN FRANCISCO, CAL.

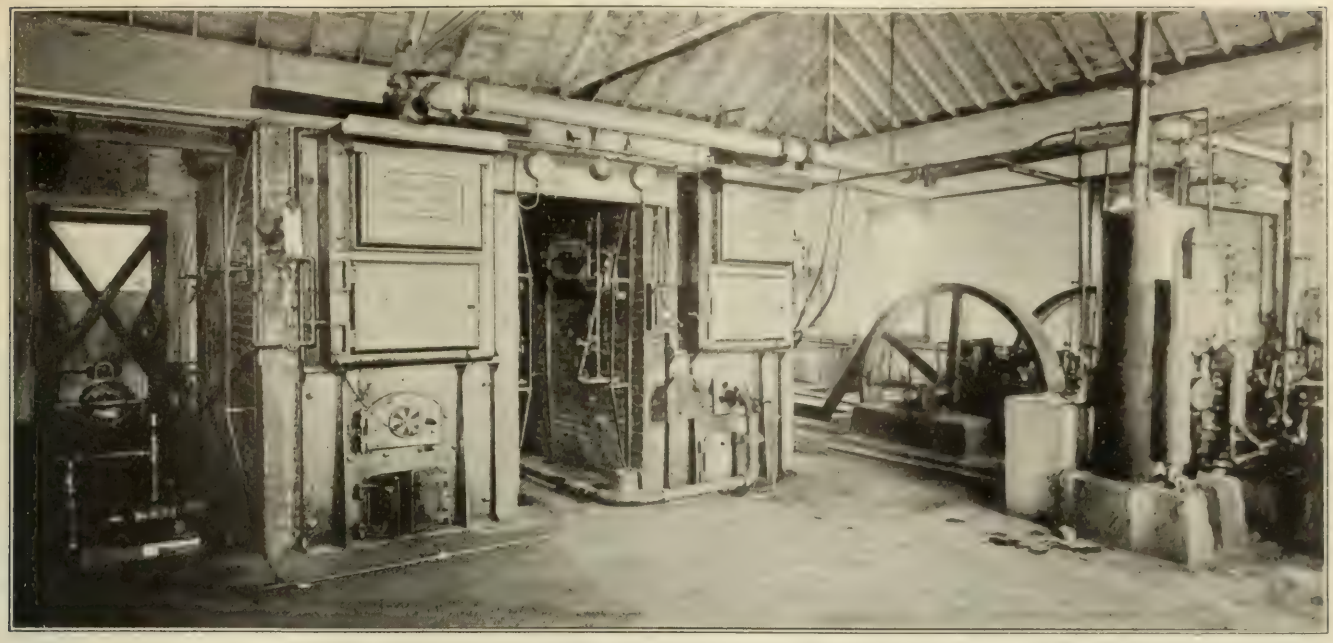

FIG. 3. POWER PLANT AT STOCKTON, CAL., USING PULVERIZED LIGNITE FUEL

the live steam, the combustion chamber and the waste gases, to determine the vacuum of the stack, draft, to weigh the feed water and to measure the steam flow.

Results Obtained

Although the conditions for efficiency at the plant were far from ideal, some very good results were obtained, both as to combustion and boiler efficiency. The average evaporation per pound of dry fuel burned was 9 lb. of water from and at 212 deg. F. The average temperature in the combustion chamber was around 2,300 deg. F. and that of the waste gases in the breeching above the boiler about 550 deg. F. The CO_2 content in the waste gases averaged 14.5 per cent. The stack dampers were so adjusted that the vacuum in the rear of the combustion chamber was 0.02 in. Fifty per cent of the ashes was carried out of the stack in suspension with the waste gases, 3 per cent lodged in the tubes and was removed by the soot blower and 47 per cent dropped either into the ash trap in the rear of the setting or onto the floor of the ash-pit in front. The latter portion of the ash proved upon analysis to be largely silica and to contain about 0.005 per cent unconsumed carbon.

Many tests were carried out at this experimental plant for the benefit of California fuel engineers, and as a result of these successful demonstrations with lignite fuel plans were drawn early in 1919 for a large steam electric generating plant at the site of the old Tesla lignite mine and three industrial power plants at Stockton to use lignite from the Ione field. A small plant has been completed at Stockton, where very gratifying results have been obtained, the powdered lignite being burned under Heine boilers, with equipment similar to that used at the initial plant at San Francisco.

When the plants now under construction in California are in actual operation and the efficiency experts have noted the great economy that will result in the generation of steam and for metallurgical purposes as well, the use of California pulverized lignite as an auxiliary to fuel oil and hydro-electric power will have received a great impetus and will without doubt soon take its proper place as a recognized and valuable California industry.

Industrial Representation in the Standard Oil Co.*

By Clarence J. Hicks†

THE labor policy of the Standard Oil Co. (New Jersey) is founded first of all on paying at least the prevailing scale of wages in the community; on the 8-hr. day, with time and one-half for overtime; one day's rest in seven; sanitary and up-to-date working conditions; just treatment assured each employee; payment of accident benefits beyond the amount prescribed by the state compensation law; health supervision by a competent medical staff; payment of sickness benefits after one year's service; co-operation with employee in promoting thrift and better social and housing conditions; and assurance for a generous annuity at the age of sixty-five, guaranteed for life after twenty years of service. Most of these features have been a part of the company's policy for many years, but it is only during the past two years that the co-operation of employees in determining these matters has been definitely assured through industrial representation.

Principle of Industrial Representation

Industrial representation, in the Standard Oil Co., is a principle rather than a procedure. It is built upon the belief that personal association of those interested in any problem leads to a mutual understanding and a fair decision as to what is right. Fully believing in this principle, representatives of employees and representatives of management evolved a simple plan, the basis of which is that it gives every individual employee representation at joint conferences on problems and fundamental principles affecting all those interested in the industry. It is based on co-operation, not antagonism; its operation makes perfectly clear both

*A paper to be presented at the Lake Superior meeting of the American Institute of Mining and Metallurgical Engineers, August, 1920.

†Executive Assistant to the President, Standard Oil Co. (N. J.).

to management and to employees that their interests are identical, that mutual understanding and co-operation insure progress and success for all. Furthermore, experience has definitely shown that representatives of the employees are not only alert for the employees' interests but are as keen as the representatives of the management in determining and insisting upon fairness to the employer.

Though the plan has been in operation nearly two years, it is an experiment, in that, being based on a principle rather than on cut-and-dried formulas of procedure, it is still subject to change and improvement. It has proved to be equally applicable in a refinery, where thousands of men are assembled, and in the sales department and producing field, where men are scattered in small groups over a wide territory. It is also in operation in several subsidiary companies. This adjustment to diverse conditions is possible because hard-and-fast rules were avoided in the belief that the human element must play an important part. Therefore the plan, to a large extent, has been permitted to build itself through experience and trial.

Co-operative Plan of Employers and Employees

The plan was brought into operation by an invitation to employees to co-operate in maintaining the company's established policy for fair treatment in matters pertaining to wages and working conditions. This invitation outlined a simple method by which the employees, by secret ballot, might elect from their own number men in whom they had confidence to represent them in conference with representatives of the management.

At the first joint conference a brief plan or agreement was evolved, which provided that adjustment of wages, including matters affecting working hours and working conditions, shall be made in joint conference between the employees' elected representatives in the division affected and the reprsentatives of the company. From the beginning, the plan stipulated that no discrimination shall be made by the company or its employees against any employee on account of membership or non-membership in any church, society, fraternity or union. Agreement was made as to offences for which employees may be dismissed without notice and also as to the offences for which an employee should be warned or suspended. Further, each employee was guaranteed recourse against unjust treatment or unfair conditions by means of a definitely prescribed method through which he, personally, or his representative may appeal his case to joint conferences of employees' and management's representatives and, if necessary, up to the highest officers of the company.

Joint Division and Joint Works Conferences

The joint works (or plant) conferences are held at regular intervals to consider all questions relating to wages, hours of employment, working conditions, and any other matters of mutual interest that have not been satisfactorily settled in the joint division conferences. These joint division conferences meet whenever needed to discuss and adjust matters within the smaller confines of a division. Many problems never go beyond the joint division conference, unless the problem develops into one that concerns other divisions. In case any matters were to come up on which the joint works conference could not agree, they would be referred to the board of directors for final decision. But as yet not one case has been referred in this manner. The decisions of the joint works conference, when they involve serious matters, such as a general increase in wages, are subject to the approval of the board of directors.

Basis of Representation for Employers and Employees

At the inception of the plan, a basis of representation was determined upon that would allow one employees' representative to be elected by approximately 150 employees, with provision for a minimum of two employees' representatives from each division. In extending the plan to other departments of the company, such as the producing field and a refinery where fewer employees are required, this basis was amended to meet conditions obtaining in that field. On this point two essentials must be kept in mind: First, that an elected representative must not have more constituents than he can easily keep in touch with; second, that the joint conferences must not be so large as to be unwieldy at times when important discussion and decisions must be had. Experience has shown that there are many advantages to be gained by personal contact of employees' representatives and management's representatives, and therefore full joint conferences are preferable to numerous smaller subcommittees.

Other Protective Methods for Employees Maintained Solely by the Employer's Funds

Entirely apart from the industrial representation plan, but equally established as a policy in the Standard Oil Co., is a method of protection for employees and their families. This is attained in several ways: Group life insurance covering, at the company's expense, every employee after one year's service, affords some financial resources to dependents in case of death of an employee—a provision that was greatly appreciated during the influenza epidemic of 1918-19. There is a fully equipped and competently manned medical department to look after the health of all employees; and there is provision for half pay during a period of sickness. An annuity plan provides for employees who retire after twenty years of service or who are incapacitated after even shorter service. These forms of financial security are considered by the company as being good business and therefore are maintained solely by the company's funds, not by either voluntary or involuntary assessments on the employees.

Training Employees to Assure Opportunity for Advancement

The company is committed to a policy of training for employees as a means of assuring, to each one who desires, an opportunity for fair advancement to greater responsibilities. The administration of training is co-ordinated with other personnel functions, such as selection of new employees, transfers and promotions. Thus each employee not only has the feeling of security in his position and his earnings but also knows that the company is ready to help fit him for advancement to any position within his capacity.

Contemporary Foreign Opinion on Sulphur and Phosphorus in Steels

During a Trip to English and French Metallurgical Centers, Opinions Were Canvassed as to How Moderate Increases in Sulphur and Phosphorus Would Influence Laboratory Tests and Service Performance of Such Steels

By HENRY S. RAWDON
Physicist, Bureau of Standards

In connection with the joint investigation now under way in America on the limits of sulphur and phosphorus in steel, a trip was made to England and France to consult the opinion of metallurgists, and of users of steels. An examination of available specifications, especially for railway steels, was made, and inquiry as to results of metal made and put into use under rather lax war-time specifications.

French Specifications

Inasmuch as French specifications for steels and similar metals are based on the foundation principle of mechanical properties, it is extremely difficult to obtain data and opinions offhand strictly applicable to problems arising in the consideration of specifications in accordance with American metallurgical practice. In specifying steels the criteria for acceptance or rejection are the mechanical properties. Chemical composition is regarded only as an index of the probable mechanical properties rather than as a characteristic of the material itself, and for this reason composition does not appear in French metallurgical specifications.

Consequently it was impossible to collect any experimental data from French metallurgical practice bearing directly upon the question of suitable limits for sulphur and phosphorus in steel. The discussion of the question was avoided, the reason given being that mechanical tests if properly conducted and interpreted will tell everything which is needed to be known, e.g., the results of shock tests will give good indications as to the phosphorus content, while the effects of sulphur may be gaged by "hot" and "cold" bends.

An official commission under the leadership of Le Chatelier and Guillet is now studying and codifying specifications for all materials of construction, but their work doubtless will not introduce a rigid adherence to chemical analysis. It is believed, however, that when the work of testing the various types of steel which are to be made has been carried far enough to warrant some conclusion being drawn, the information contained in the French specifications will be of value in showing to what extent the composition of the steels may be varied with respect to its sulphur and phosphorus content and still meet them satisfactorily. They may also offer some suggestions as to suitable tests to be made upon certain special products.

French Metallurgical Opinion

The following was formulated as the general opinion concerning the Bureau's program in the sulphur-phosphorus investigation after consultation with prominent French metallurgists:

Tension tests will tell but little concerning the effect of sulphur and phosphorus in the small amounts allowed, particularly if all the specimens are to be cut longitudinally from the steel. Sulphur as manganese sulphide in particular has its greatest effect in reducing the *transverse* strength of steel. Dynamic tests should also be made; in particular, impact or shock tests. It is in this respect that phosphorus has its pronounced effect.

All agreed that a preliminary examination should be made to determine to what extent segregation had taken place; this examination was ranked as of prime importance and a steel, e.g., of 0.07 per cent sulphur, if unsegregated, was mentioned as being preferable to one of 0.04 per cent S if pronouncedly segregated.

Regarding rivets of high sulphur content, the opinion was held that if the material can be worked to the shape of rivets satisfactorily, no trouble will be experienced in the later processes of riveting nor could any reason be given why material as high as 0.07 per cent sulphur should not behave as satisfactorily in service as steel of 0.05 per cent sulphur.

French Railway Material

Great emphasis was placed by railroad engineers upon the preliminary metallographic examination for the purpose of revealing unsoundness and segregation. Although the material which has been put into service on the railways of France during the past few years has in many cases been far below the former standards, still no reliable data are available regarding its behavior. The conditions of service have been so severe and unprecedented that every bit of metal has been worked to the limit and removed either because of failure or wearing out. It is therefore not possible to express any reliable opinion as to its suitability for the service it was intended to stand.

In general, the French were of the opinion that American specifications for sulphur and phosphorus are too stringent and if care was taken to have uniform distribution of these elements in the material, it would be found that a steel of 0.07 per cent sulphur as compared with 0.05 per cent sulphur would meet all the required specifications as to mechanical properties and be suitable for use.

Ideas of English Metallurgists

In England, as in France, but little experimental data bearing on the subject of the influence of sulphur and phosphorus were available and it was necessary to depend upon the opinions of those consulted. A research of value and interest in this connection is one that is being undertaken by the aëronautic section of the British Engineering Standards Association. In order to determine the effects of sulphur and phosphorus up to the prescribed war-time specification limits on cold-drawn carbon-steel tubing such as is used in airplane

construction, a series of ingots of steel of special phosphorus and sulphur content are to be obtained and then worked down into the form of tube and sheet and the product thoroughly tested. It is planned to collect ingots made under war-time conditions, of three sulphur contents up as high as 0.07 per cent (viz., 0.03, 0.05 and 0.07 per cent), with a high and low phosphorus content in each case. Later it is hoped that other types of steel entering into airplane construction will be investigated in a similar way. The fact that this research is being carried out along exactly the same lines as the one planned in the United States is evidence of the lack of available experimental data in English metallurgical practice from which a solution of the problem might be made.

On account of the larger number of metallurgists consulted in England a greater difference of opinion concerning the effects of sulphur and phosphorus upon steel was expressed than was the case with the French metallurgists. The following opinions concerning the program of the research outlined by the Bureau of Standards and its associates were expressed by nearly all consulted:

Opinions Concerning the Research Program

The tests to be made should be of two general types, first, upon the behavior of the material during fabrication and second, mechanical tests upon the fabricated material. Tension tests should not be depended upon to differentiate the effects of sulphur in varying amounts no higher than those laid down in the program. The transverse tension test will be found much more useful. The opinion was held by some, however, that the difference between longitudinal and transverse tensile strength which exists in steel of normal sulphur content is often of sufficient magnitude to mask entirely any additional effect due to a higher content of sulphur. The importance of dynamic tests, particularly some form of impact test, was emphasized as well as the simple bend test.

The opinion was expressed by nearly all that if it were possible to form rivets satisfactorily from steel of rather high sulphur content they would behave satisfactorily during the riveting. A test suggested by several as useful in this case was a cold-heading process to determine the effect of the sulphur.

The importance of the examination to determine how uniformly the sulphur and other metalloids are distributed throughout the steel was emphasized strongly by all and the statement made that it would probably be found that in order to be absolutely safe it will be necessary to penalize a considerable amount of good material on account of occasional bad specimens due to segregation.

In regard to the general subject of necessary tests, one very eminent metallurgist said that no matter how many laboratory tests were made and how carefully they were carried out there is no way of translating the results obtained into service. The suggestion was made that in each case a comprehensive series of service tests should be made and that until the results of such service tests were available it would be unwise to change specifications which were known to be safe. In other words the wide margin of safety obtained with rather rigid specifications is a much wiser policy than an uncertainty due to new specifications which had not been fully and thoroughly tried out in practice.

Regarding the method of adding sulphur in making up the heats of special composition, all consulted were of the opinion that the sulphur should be added during the melting (preferably as iron sulphide) rather than at the end of the process. Phosphorus may be easily obtained from high-phosphorus pig iron; the use of screw stock high in sulphur and phosphorus is admirable for addition purposes in those heats in which a considerable amount of both sulphur and phosphorus is desired. It is essential, however, that the effect of each element be investigated alone before the more complicated case of the two combined be taken up.

It was thought that this difference existed between "residual" and added impurities: Residual impurities are more uniformly distributed throughout the finished steel, while added sulphur, for instance, may exist in considerable amount as ferrous sulphide and hence is apt to be more detrimental in its effects upon the properties of hot metal.

None of the men consulted would agree to the contention that within certain limits sulphur and phosphorus are not decidedly detrimental in themselves but are only indicators of some other undesirable condition. All were of the opinion that both sulphur and phosphorus had a characteristic effect upon the mechanical properties of the steel in which they occur, although such effects may be augmented by other undesirable conditions which may accompany amounts somewhat above the usual percentage. Such undesirable conditions may possibly consist, for example, in incomplete deoxidation or in the nature and distribution of the slag, more of it being retained by the metal. In general, however, most of the men consulted stated that they could not readily visualize and describe these concomitant conditions and were inclined to consider the matter worthy of very little consideration.

One important point brought out by a keen student of the question was that the simultaneous effect of carbon and phosphorus should be taken into account in the case of high-phosphorus steels. The hardening effect of phosphorus is much augmented by that of carbon, both elements affect the material in the same direction. In a low-carbon steel a rather high-phosphorus content can be used with safety, while the same amount in a high-carbon steel such as spring steel would be viewed with suspicion and alarm.

Among special tests mentioned as probably necessary for some products was a determination of the effect of high sulphur (and phosphorus) upon the corrodibility of the metal. This was mentioned as being of grave importance in the case of boiler tubes and other materials subjected to similar conditions.

Divergent Views of English Manufacturers

Opinions held by representatives of different steel manufacturers on the subject of the effect of sulphur and phosphorus differed radically. The extreme view taken by one Sheffield firm was that they were convinced as a result of their war experience that a sulphur content as high as 0.07 per cent was entirely safe provided the steel was "properly controlled in the melting and pouring." Thousands of airplane crank shafts were made by this company during the progress of the war with a sulphur content as high as 0.07 per cent. It was claimed that there was no evidence that any of these had ever failed in service because of the higher sulphur content, although it is undoubtedly true that such ma-

terial is as severely stressed in service as anything in the entire engineering field. The stand is taken that sulphide of manganese is no more detrimental in its effects upon steel than are other inclusions and should be regarded in the same light.

The other extreme was held by another company in the same region, that anything that breaks up the continuity of the metal is to be regarded as detrimental to the steel and that the effort should be to produce steel which is as pure as possible in this respect. Hence sulphur should be maintained as low as possible in amount. The representatives of this company were quite frank in saying that they expected very little from the research that the Bureau has under way.

Most of the manufacturers, however, take an intermediate stand. Provided there is but little segregation and the metal is uniform in composition (special ingot types were recommended by some as being a desirable feature of the research on sulphur and phosphorus for this reason), the sulphur and phosphorus can be safely raised to a percentage of 0.07. By some this figure was placed still higher, 0.08 to 0.09, "depending upon the manufacturer who made the steel."

The suggestion has been offered by a few that the manganese content should be taken into account, particularly in those steels of high sulphur content. Most of the steel men, however, thought that for the range of sulphur content under investigation this was a refinement that would be beyond the control of the furnace man in making up his charge.

Sulphur and Phosphorus in Railway Materials

Although a considerable difference of opinion exists among users of this type of steel, it may be stated that the general tendency of the railways is to get back to the pre-war specifications as quickly as possible. Although it was necessary to relax the specification limits considerably during war time, the step was taken by the railway officials only with the understanding that the responsibility for anything arising from the use of such untried material should be assumed by the government.

It is felt that since the war-time experience with the newer material has been made under such unusual conditions of service, together with the fact that complete records of such materials were not made, there is no warrant for the continued use of this type of material. They are interested in obtaining material which they have found by experience to be entirely safe and claim to be finding no difficulty in obtaining it. It may be noted that in some cases the material used is not as closely specified in respect to sulphur as the present British Engineering Standards specifications call for. Locomotive crank axles, for example, are allowed 0.04 per cent sulphur by the specifications of the Midland Ry., while 0.035 is the amount allowed by the B. E. S. specifications. In general, the stand taken by the users of railway materials in England appears to be that the upheaval which occurred has not shaken their faith in their old specifications.

Summary and Conclusions

1. But very little data strictly applicable to the present research on sulphur and phosphorus in steel were obtainable in either England or France. This is partly accounted for by the different basis used abroad in drawing up specifications for metals.

2. A research conducted along exactly the same lines is now being carried out by the British Engineering Standards Association to determine the effect of sulphur upon a certain type of steel product. The inference to be drawn is very evident—there are no data available for settling the question, but direct experimental evidence must be resorted to.

3. The much-used tension test is to be regarded as only a start in the mechanical testing necessary for determining the effects of varying amounts of sulphur and phosphorus upon steels. Dynamic tests should be given full consideration as well as tests which will show the properties of the metal in a transverse as well as in the longitudinal direction. The behavior of the material during fabrication should be regarded as one line of testing of equal importance with mechanical tests on the finished metal.

4. The necessity of extensive service tests was emphasized, since no matter how many laboratory tests are carried out there is no way of interpreting such tests in terms of ordinary service.

5. The opinions expressed by manufacturing metallurgists differ very widely as to permissible limits for sulphur, diametrically opposing views being taken.

6. Regarding the method for obtaining suitable sulphur and phosphorus contents in experimental heats to be made, the general opinion appeared to be that the additions should be made during the heat and not at its close. Regarding the subject of "residual" vs. "added" sulphur, the general opinion was held that the difference consisted largely in the physical condition of the two and no *clear, definite* expression of opinion could be obtained as to the possible detrimental effect of some obscure condition accompanying high percentages of sulphur and phosphorus.

7. The general tendency of the English railways is to revert to the pre-war specifications for ordering materials. No such generalization can be made regarding the French practice, on account of the greater effect that the war had upon the systems as well as the fact that at the present time all specifications are being reviewed and unified by a national commission appointed for this purpose.

Meeting of Electric Furnace Association

Definite plans have now been made for the meeting of the Electric Furnace Association in Boston. The business meeting and election of officers will be held at the Copley-Plaza Hotel at 1 p.m. on Thursday, April 8, and will be combined with a luncheon. At 2 p.m. there will be a general meeting, also at the Copley-Plaza, which will be open to all who are interested in the electric furnace industry. The subject of the discussion will be "Adequately Trained Men an Urgent Need of the Electric Furnace Industry." This subject has been chosen at the instance of a number of electric furnace operators. Papers have been prepared by makers of furnaces and equipment and by electric steel manufacturers. A number of engineering institutions will also discuss what they are doing to train men for metallurgical work.

On Friday, April 9, the Association will join with the American Institute of Electrical Engineers and the American Electrochemical Society in their discussions on "Electrically Produced Alloys" and "Power for Electrochemical Purposes." During the afternoon all three organizations will probably make a trip to the plant of the General Electric Co. at Lynn.

The Physical Condition of Workmen

By Chesla C. Sherlock

COMPENSATION is ordinarily payable to workmen who have been injured through accidents which arise in the course of the employment, as well as out of it. If the workman dies as a result of his injury, the compensation is payable to his dependents.

All workmen, unfortunately, are not of the same physical condition at the time of their injury. A slight strain that would not affect a normally healthy man in the slightest may cause the death of a workman suffering from heart trouble.

The question naturally comes to every employer, at some time or other, whether the law intends to hold him liable for the physical condition of his workmen in a compensation way. Is the employer entitled to charge off the pre-existing condition of the workman?

Here we have a workman who has served his employer through long years at heavy labor. In the course of time, he is unable to continue at work; he is like an old broken down horse; he has suffered a cardiac breakdown which absolutely prevents him "carrying on." Is he entitled to compensation?

Instances Cited

In another instance, a workman may be suffering from heart trouble. He has been warned by his physician not to do any lifting and to be very careful as to the sort of work he does. But in the struggle for a livelihood he takes a job at lifting and conceals from his employer the facts in his case. To the employer he is apparently able-bodied and capable of carrying on the work. A few days after he goes to work, the strain is too much for his weakened heart, and he dies. Is he entitled to compensation?

In another case, a workman may apparently be in fine health and spirits. He has been concealing a hernia from his fellows, fearing that if it were known he would be discharged. In the course of his work, he is called upon to do some lifting which would not in any way affect a normally healthy man, but in his case it strangulates his hernia and he dies before relief can be secured. Is he entitled to compensation?

Or, and this case is not so visionary as it might seem, suppose that a workman is unable to get up on "high places." He is required to wash windows or repair roofs and, finding himself on the high spot, suffers a faint spell, falls and injures himself, or because of his weakened heart has an attack of heart failure and dies. Is he entitled to compensation?

I might enumerate many other instances such as these, but that is unnecessary. What the employers want to know is the law and the basis upon which the courts and commissions arrive at their decisions.

The General Established Rule

The question of pre-existing condition is one of the hardest that ever confronted the courts under the compensation system. A general rule has finally been established which is, I think, generally accepted as being a happy solution of the problem.

The underlying principle of the compensation acts, it will be recalled, is that since the workman has, during his productive years, added something to the wealth of society, society should compensate him (share his loss) when industry robs him of his earning capacity. This is a great, humane principle, and as near a socialistic principle as you will find supported anywhere by the law.

If the physical condition of a workman was to be taken into consideration, it would be possible for the employer to defeat the very purpose of this principle, in many cases, by using the workman up to the point where he develops, or is about to develop, incapacity or predisposition to injury or disease, then discharge him and prevent him obtaining compensation. It would further operate to close the doors of industry to this man so that he could not obtain employment elsewhere, for no employer would be willing to run the risk of employing the fellow, under the circumstances, and having him "die on his hands."

It would mean that employers would have to take physical examinations of their workmen at regular intervals, especially in first employing them, in order to protect their own interests. This would not only add a burden to the cost of labor turnover and management but it would operate to destroy the effectiveness of the compensation acts, except in clear-cut cases of injury by accident.

Attitude of the Courts

The courts were fortunate in early seeing the matter in this light. They said that it is unfortunate if an employer employs a man who is predisposed to injury or disease, because of impaired physical vigor, but the law cannot take any affirmative action in the matter. If the man employed is sufficiently able-bodied to be hired by the employer, then the employer cannot be heard to come into court when subsequent events disclose that the workman suffered from pre-disposition to injury or disease and whine about his tough luck. To permit this would be to destroy the very underlying principle upon which the compensation system rests.

And so we find the courts saying that compensation is not necessarily barred because a claimant suffered from an impaired physical condition which rendered him more susceptible to injury than a normally healthy man.

It must be remembered, however, that the right to compensation is based upon an injury by accident arising out of and in the course of the employment. If the workman is doing something which produces an accidental happening injuring or incapacitating him, however slight it may be, he is entitled to compensation regardless of his pre-existing physical condition.

But as an English court has said: "No compensation is recoverable for incapacity caused by cardiac breakdown which was not due to any sudden strain, but was the natural result of the workman continuing to do work which was too heavy for him."

The rule is stated in this country that if the workman was doing his ordinary work in the ordinary way and something happened causing him to die or become incapacitated, he cannot receive compensation, as the injury clearly arose out of his impaired physical condition, there being no fortuitous event at the time indicating that it arose by accident out of and in the course of the employment.

It is a general rule that if, at the time of the accidental injury, the workman was capable of performing the work of an able-bodied man *in that employment*, pre-existing conditions cannot be successfully pleaded in bar of compensation.

Legal Notes

By Wellington Gustin

Duties and Liabilities Where Wrong Products Are Delivered—Express and Implied Warranties

Some very workable points in law are involved in the case of Samuel and others against the Delaware River Steel Co., recently decided in the Supreme Court of Pennsylvania. (107 A., 700.)

It appears that the steel company purchased two carloads of "roll scale" from plaintiffs, who are brokers in steel and iron products at Philadelphia, to be delivered to defendant at Chester, Pa. Plaintiffs purchased the roll scale from the Lebanon Valley Iron & Steel Co. and ordered shipment made directly to defendant's mill. The defendant claimed that upon unloading the material it was found one of the cars contained largely "mill cinder," a product of less value than roll scale. However, the entire shipment was used within the day following delivery. A week later a formal written complaint was made by defendant saying that the material in one of the two cars consisted approximately of 75 per cent cinder and 25 per cent roll scale, and that it would expect the bill to be rendered on that basis. Later defendant proposed to pay the market price of cinder, and this offer was refused by plaintiffs, who contended that the product delivered was roll cinder, and further that even if it were not such product, by accepting and using the car before making complaint defendant waived the right to object that it was not the article ordered.

This became the issue in the case. The trial judge submitted to the jury the question whether the material delivered was roll scale or mill cinder, with the further instruction that if it found it was mill cinder, to determine whether it was practicable for the defendant to have offered to return the product, and that if mill cinder was delivered, if defendant discovered the fact before it was used, there should have been an offer to return, and in absence of such offer defendant would be liable for the contract price. On this the plaintiff was given a verdict by the jury for the difference between the amount paid by defendant and the price of roll scale. Now, this trial court held that it was the duty of the defendant to notify the plaintiff, upon discovery that the product received was not "roll scale," and before using same.

On appeal to the Superior Court the judgment was reversed, because it held that the proposition of law laid down above was error. However, in reversing this, the court directed the entry of judgment for defendant, and from this judgment an appeal was made to the Supreme Court.

Implied Warranty, Like the Express Warranty, Survives Acceptance

This last court said it was well established that, in the sale of a chattel by sample or description, an implied warranty attaches that the article shall be of the kind ordered.

Now, where there is an express warranty the general rule is that it survives acceptance of the goods, and the purchaser may thereafter sue for the breach of said warranty, or may set off damages for such breach in an action brought by plaintiff for the purchase price of the goods.

And now the question is whether the implied warranty, that the material was of the kind ordered, was also one which survived the acceptance and use of the material without previous notice to the plaintiffs. Said the court, there was considerable conflict of opinion in the authorities, but the greater weight in courts of other states was that the implied warranty, like the express warranty, survives acceptance, even though the defects were known at the time the commodity was accepted and used. And so the court held. Notice to plaintiff before use was unnecessary.

However, it found that the Superior Court also fell into error in directing judgment for defendant in that plaintiff's evidence that the material furnished was roll scale, though contradicted by defendant's evidence that it was mill cinder, made a question for the jury to decide.

Hence it was ordered that a new trial be had to determine that question.

International Forge Co. Judgment Affirmed by Pennsylvania Supreme Court

In the case of the International Forge Co., Inc., against Paul S. Reeves & Co., Inc., to recover the value of certain lost metal, the judgment for plaintiff for $2,146.35 has been affirmed in the Supreme Court of Pennsylvania. (107 Atl., 837.)

The Reeves company had entered into a written contract with the plaintiff, the International Forge Co., to manufacture castings out of materials to be furnished by it. This contract provided that the Reeves company should "stand all metal losses," and this action was brought to recover the value of lost metals furnished to it.

There were originally two assignments of error given as reasons for asking a reversal of the judgment. The first was withdrawn and the second was not supported by proper complaint. Hence the judgment was affirmed.

Liability for Guaranteed Analyses

The constitutionality of the Florida laws regulating the sale of fertilizer was recently presented to the Supreme Court of Florida in the case of Adams against the American Agricultural Chemical Co. The plaintiff had entered suit against the defendant company, alleging that the defendant, being engaged in the business of handling and selling commercial fertilizers, sold to him fertilizers bearing a stated guaranteed analysis, and that upon an analysis made by the state chemist, it was discovered that plaintiff had been defrauded by reason of deficiencies of constituent elements in the fertilizer, and the plaintiff claimed double the price of the fertilizer as his damages, as provided by statute. Among other grounds, the chemical company defended on the contention that the sections of the statutes as named above were unconstitutional, for the reason that their effect is to deprive fertilizer manufacturers and dealers of their property without due process of law.

Provisions of the Statute

The first section of the statute referred to provides for an analysis of the fertilizer purchased, by the Commissioner of Agriculture, and the second permits a recovery of twice the amount paid for the fertilizer. The last-named section contains this provision: "In case any purchase be made of any manufacturer or agent of any person or persons residing out of the State of Florida, manufacturing, compounding or furnishing

for sale any such commercial manure or manufactured fertilizer, cottonseed meal, castor pomace, tobacco stems, tobacco dust or tobacco meal, the purchaser thereof may, at his option, proceed by attachment, as now provided by law in case of non-resident and absconding debtors, against any such property, rights or credits of any person or persons selling, manufacturing, compounding or furnishing said manures or fertilizers when such property, rights or credits can be found within the limits of the state."

DICTUM OF THE COURT

Passing upon the question involved, the Supreme Court said in effect (82 So., 850): "Section 1,272, General Statutes of Florida, gives 'to any person purchasing any fertilizer or fertilizing materials from any manufacturer or vendor who shall . . . discover that he had been defrauded by reason of adulteration or deficiencies of constituent elements, . . . in the fertilizing material so purchased,' a right of action against the manufacturer or vendor, and the right thereby given is not limited to those who discover such fraud 'upon an analysis by the state chemist.'

"Section 1,271 . . . provides a method by which the user of fertilizer, if he be a citizen of this state, may determine whether his fertilizer measures up to the guaranteed analysis, and allows him to use the certificate of the state chemist as prima facie evidence in any suit brought under section 1,272; but such certificate, while competent, is by no means exclusive evidence as to the real analysis, the state chemist being subject to the ordinary rules of cross-examination and contradiction.

"The cause of action given by section 1,272 lies in fraud, and the declaration should be based upon the fact of the fraud, and not upon the analysis by the state chemist; such analysis being evidence only of the real cause of action, to wit, fraud.

"The primary purpose of section 1,272 is to afford compensation to the purchaser and user of fertilizer for his probable, though uncertain, loss resulting from the use of inferior fertilizer. The measure of recovery is in the nature of liquidated damages.

"Sections 1,271 and 1,272, General Statutes of Florida, do not appear, from the facts presented, to deprive the defendant of property without due process of law, nor to deny to it (a corporation) the equal protection of the law, contrary to the state or Federal Constitution.

"The requirements of due process of law and of equal protection of the laws are satisfied if there is no unauthorized and merely arbitrary exercise of the powers of government, to the detriment of the people, or some of them; and inasmuch as the statutory damages of double the price paid for the fertilizer are not shown to be unjust, unreasonable, nor arbitrary in this case, and inasmuch as the statute applies alike to 'any manufacturer or vendor' of fertilizer, the constitutional rights of the defendant do not appear to have been violated.

"A corporation is not a 'citizen,' within the 'privileges and immunities' provisions of the Federal Constitution.

"One who is not himself denied some constitutional right or privilege cannot be heard to raise constitutional questions on behalf of some other person, who may at some future time be affected."

Therefore the judgment of the trial court in favor of the chemical company, which had contended the statutes were unconstitutional and void, was reversed.

Air Conditioning Prevents Explosions Ignited by Static Electricity

ONE of the three principal dangers of factories where quantities of chemicals are being handled is that of explosion due to chance sparks from static discharges, and this is one of the most subtle (because frequently untraceable) causes of such accidents. Oftentimes such explosions result disastrously, and case after case remains, in its origin, a mystery, the safety engineers of the factory not being able to determine beyond doubt the direct cause, because of some hidden and unusual static cause, a "freak"—and freaks are something to which static discharges are very liable.

Of serious consequence is the low relative humidity in the winter, when the possibility of static discharge is greatly increased.

The safest way to prevent such explosions, due to the ignition of mixtures of combustible vapors and air, is in the use of all reasonable precautions, and then an air-conditioning system which eliminates dangerous atmospheric conditions. Properly-conditioned air is "climate made to order." It means air that is sufficiently moist to cause the air to become a good conductor and carry away the charge as formed, and prevent it building up a sufficient potential to form a spark. Dust particles, being moistened in this way, tend to fall to the floor, rather than float in air currents. But the air must be sufficiently dry so that chemical work may be carried on entirely free of all risk that hydroscopic materials will absorb moisture.

According to the B. F. Sturtevant Co., of Boston, specialist in air conditioning, the field of chemistry and metallurgy has furnished one of the most severe tests of the application of air conditioning which could be imagined. That it has emerged from this test with ample proof of its value and advantages not possible in any other way has been established in all cases and under a great variety of conditions. To quote the Sturtevant company:

"The exact nature of the work done in the chemical laboratory, manufactory, dye house and mixing room calls for minute care in temperature and humidity, if ideal results are to be realized. This is more or less of a truism, but even now all concerns do not fully recognize the important part that atmospheric conditions play in the rate of production.

"When important work is in process, calling for the combination of chemicals under certain definite conditions, a degree one way or the other may mean all the difference between success and failure. Or it may possibly be the means of a disastrous explosion, as was the case some time ago with a large plant which was completely destroyed, due to a chance frictional spark caused, possibly, by a too-high static condition in the atmosphere. With proper air conditioning, chemical processes and combinations involving the handling sometimes of highly hydroscopic materials are performed under ideal conditions, assuring maximum success in results. Where moderate temperature is required, where humidity must be accurately regulated and maintained, where weather conditions cannot be allowed to interfere with difficult and costly work, there air conditioning has proved its vital usefulness in plants of every kind, all over the country."

Synopsis of Recent Chemical and Metallurgical Literature

Colloidal Clay Soap.—What is described as a revolution in soap making is the subject of a lengthy and analytical article in *Chemical Age* (London) of Jan. 17, 1920, in which the use of colloidal clay as an addition to or as an alternative for some of the customary constituents of soap is shown to possess properties of great value.

F. E. WESTON, the writer of the article, is stated to have been associated in a consultative capacity with an important industrial undertaking in connection with the utilization of colloidal clay. This clay, he states, "belongs to the general class of 'suspenoids' and is a reversible colloid, since it is possible to disperse it in water or throw it out of colloidal solution at will.

"True colloidal clay is prepared from china clay. One of the many and varied applications of colloidal clay is that of its use as an adjunct in the manufacture of soap, not as a 'filling' material or as an adulterant, but as an actual substitute for soap material."

After describing the usual constituents of soap, Mr. Weston refers to the conclusion arrived at by Spring that the concentration of soap on the surfaces of the adsorbing bodies is the chief factor in the detergent action of soap. According to Michaelis, adsorption is the greatest for those substances which produce the greatest lowering of the surface tension of a liquid when in solution in that liquid. He points out that soap dissolved in water considerably lowers the surface tension of water against air; that clay can be brought to such a highly colloidal state that it closely resembles soap in its physical behavior; and that when properly incorporated with soap it actually increases the lathering and detergent properties of the latter. "Chemically, soap and clay belong to two distinct types of compounds. Physically, however, the solutions of these bodies resemble each other closely; they both possess emulsifying power, both have the power of 'adsorbing' dirt, grease, etc., and both have detergent properties."

Incorporated with soap, the clay tends to lower the surface tension of water to a greater extent than soap itself. Experiments with high-class toilet soap and a soap made up of 80 per cent soap plus 20 per cent colloidal clay showed that the soap containing the colloidal clay lowered the surface tension 9.1 per cent and 6.9 per cent more than the pure soap, at 20 and 45 deg. C., respectively. Lathering experiments were also carried out, and the lather obtained by adding collodial clay to the soap was found to be much greater than that obtained by the soap itself; moreover, in all cases the lather was of a firmer nature and was more persistent.

Other experiments are described by Mr. Weston, and objections against the use of alkalis to increase lathering and detergent properties of soap are given, and he proceeds to state that the custom of taking, as a criterion of a soap, the percentage of fatty acids present therein will no longer hold good, "since colloidal clay contains no fatty acids," whereas the experiments show that such clay increases the lathering and detergent properties of soap. It is not asserted at present, however, that fatty acids can be entirely dispensed with, but that their present proportion can be halved. It is pointed out that colloidal chemistry "in its application to industrial problems is only just beginning to be realized"; it is a "branch of chemistry still in its infancy."

In conclusion, it should be noted that *Chemical Age* remarks: "According to Mr. Weston, the colloidal clay, which forms the subject matter of his article, is prepared by a patented colloidal process, and it would appear that many varieties of clay, both in Great Britain and in other countries, may be found amenable to the process."

Old Rails With High Internal Strains Contained No Fissures.—Significant studies of old rails were carried out recently to test the theory that transverse fissures in rails are produced by permanent strains set up by the distortion of the metal in service under rolling loads. As detailed by W. C. CUSHING, chief engineer of maintenance, Pennsylvania Lines West of Pittsburgh, in a report (No. 84) to the rail committee of the American Railway Engineering Association, a number of old rails were taken out of the track and examined for structure, internal strains, segregation, and existence of transverse fissures.

Rails that had been in service from ten to forty-five years were examined; some of the oldest were of wrought iron, others rolled from iron and steel pile, while those ten to twenty-five years old were of bessemer steel. All of them "were carefully examined for transverse fissure defects, but none were found." Nevertheless their internal strains were very high according to 10-in. strain-gage measurements which were made on various strips $\frac{1}{2}$ x $\frac{1}{8}$ in. cut from different parts of the rails.

In the old wrought-iron rails, head strains corresponding to 24,000 to 27,000 lb. per sq.in. in compression were found, which appeared the more serious because the material had a low elastic limit, 26,670 to 48,760 lb. per sq.in. The piled rails showed maximum head strains of 24,000 lb. per sq.in., and the elastic limit of the material ranged from 33,700 to 53,830 lb. per sq.in. Still higher internal strains, however, were found in steel rails that had been in service twenty to twenty-five years, several measurements of 36,000 and 33,000 lb. per sq.in. being made, as against elastic limits of 46,500 to 58,450 lb. per sq.in. These high values of permanent strain were measured at the surface of the head and on the side opposite the gage side, in nearly every case. One abnormal result was a reading of 57,000 lb. per sq.in., tensile stress, in the flange of an 85-lb. rail that had been in service from 1898 to 1917; Mr. Cushing calls this "extraordinary and inexplicable."

Segregation was rather high, particularly in the rails exhibiting the highest internal strains, and at the same time these rails showed low elastic-limit load in the quick-bend test (though not in tests in direct tension). Mr. Cushing concludes:

"If severity of service, especially by exceedingly heavy wheel loads, be the sole cause of the defect known as transverse fissure, these rails, after their unusually long service, and in some of the cases under the heaviest wheel loads in use, would be sure to be filled with transverse fissures. That such was proved by careful examination not to be the fact, that rails adjacent to and undergoing precisely the same conditions of serv-

ice as those in which transverse fissures have been found do not have any, and that rails never put into service as well as those which have been in service have been shown by Waring and Wickhorst to contain microscopical cracks, seems to prove beyond a doubt that the cause, the real cause, of transverse fissures must be sought in the process of manufacture. The wheel loads are the instruments of development from the initial defect, and it is true that the service has become uncommonly severe."

Transformers for Electric Furnaces.—J. L. THOMSON gives in the London *Electrician* of Jan. 30 and Feb. 6 a comprehensive discussion of the present and future status of transformers for electric furnace work. The author states that at the present time electric steel furnaces have been designed for capacities of fifteen tons and that the future will demand larger sizes up to thirty or forty tons. Assuming that 200 kva. is required per ton, transformer groups of 6,000 to 8,000 kva. will be required. While transformers of larger capacities have been designed, this particular problem is complicated by the low voltage and heavy currents required. The writer then deals with the design of the furnace with special regard to the heavy magnetic fields involved, the

APPROXIMATE WEIGHT OF FURNACE TRANSFORMERS

mechanical stresses and furnace layout. He states that in order to reduce the possibility of a heavy choking effect and unbalanced voltages, the following suggestions may be useful: (1) Transformers should be placed as near to the furnace as possible, so that heavy low-voltage leads may be of minimum length. (2) Low-voltage leads of the various phases should be symmetrically placed with respect to transformers and furnace. (3) The area between positive and negative low-voltage leads should be as small as possible and also that between phases so that inductance may be a minimum. (4) Low-voltage leads for heavy currents (above 5,000 amp.) should be in multiple and interleaved from the transformer to a point as near the furnace as possible. This will keep the inductance low and make that of each lead approximately the same, thus insuring that each parallel lead takes its proper share of the load. (5) Heavy current leads should not be run near any heavy magnetic structure such as girders or supporting columns unless both the positive and the negative leads are run together and interleaved. (6) No magnetic material should form a closed circuit around any positive or negative conductor, or heavy currents will be induced in that circuit. The positive and negative conductors interleaved may be run through a magnetic circuit. Clamps for heavy-current leads should be of non-magnetic material.

Recent Chemical and Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Camphor From Isoborneol.—Nitric acid, 600 lb., sp.gr. 1.4, is placed in a stoneware kettle provided with a stirrer, and heated to 40 deg. C. Two platinum electrodes in the form of plates (1 in. wide x 6 in. long) separated by insulating blocks are suspended in the acid. While the stirrer is at rest about 0.5 lb. of isoborneol is dropped upon the top of the immersed electrodes and a current of 1.6 volts and 30 amp. passed until the reaction has started, as shown by the evolution of red fumes. The electrodes are now removed and isoborneol added in small quantities with constant stirring until 150 lb. has been added. The temperature is held at 40 deg. C. by means of cooling coils. The camphor nitrate which floats as an oil on the surface of the weak acid is decanted and drowned in an excess of water, whereupon it breaks up to form camphor, which is washed, dried and purified by sublimation. (1,324,140; ROLAND L. ANDREAU, of Wilmington, Del., assignor to E. I. du Pont de Nemours & Co.; Dec. 9, 1919.)

Toluene From Xylene or Solvent Naphtha.—BENJAMIN T. BROOKS, of Pittsburgh, Pa., has found that the xylenes, which are of little commercial value, can be converted into toluene by a "cracking" process. Crude solvent naphtha containing 70 to 80 per cent of the three xylenes is heated with dry aluminum chloride under a reflux condenser so regulated that the toluene vapors can escape as formed, at a temperature between 105 and 115 deg. C., while the xylene vapors are returned to the still. The condensate will generally run about two-thirds toluene, one-sixth benzene and one-sixth heavy oils (xylene, etc.), and may be fractionated in a suitable still. (1,324,143; assigned, by mesne assignments, to E. I. du Pont de Nemours & Co.; Dec. 9, 1919.)

Strontium Peroxide.—When strontium oxide is heated to about 400 to 500 deg. C. with oxygen at a pressure of 1,500 to 1,800 lb. per sq.in. strontium peroxide of high test (over 85 per cent SrO_2) is formed. (1,325,043; JAMES B. PIERCE, JR., of Charleston, W. Va.; Dec. 16, 1919.)

Pyrocatechin Aldehyde.—If piperonal is treated with thonylchloride at the temperature of the water bath, a reaction takes place according to the equation:

$$R.CHO + SOCl_2 = R.CHCl_2 + SO_2 \quad (1)$$

By treating the piperonaldichloride (piperonylchloride) thus obtained with four molecules of chlorine, dichlorpiperonylchloride is formed. This compound when hydrolyzed yields pyrocatechin aldehyde, carbonic and hydrochloric acids being split off. Reaction (1) is excellently suited for the protection of the aldehyde group, so that a good yield of pyrocatechin aldehyde is obtained. (1,326,793; LUDWIG SCHMIDT, of Munich, Germany; Jan. 6, 1920.)

Hexanitrodiphenylamine.—It has previously been considered impossible to use mixed acid in the preparation of symmetrical 2.4.6.2'.4'.6'-hexanitrodiphenylamine from 2.4-dinitrodiphenylamine. The usual procedure has been to nitrate the latter compound

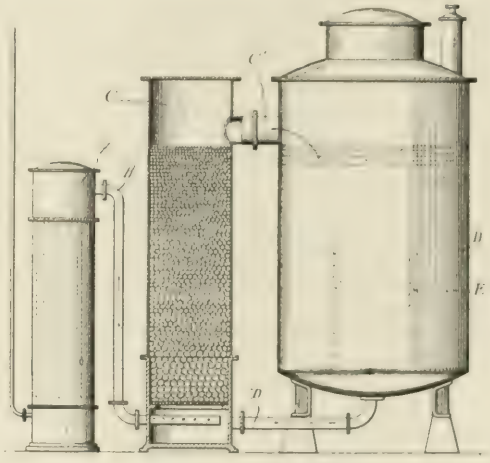
with 50 per cent nitric acid to form 2.4.2'.4'-tetranitrodiphenylamine, and to complete the nitration with 90 per cent acid. In working with such concentrations of nitric acid, the use of lead lined or enameled vessels is imperative. JOHN MARSHALL, of Swarthmore, Pa., has devised the following procedure, in which mixed nitric and sulphuric acids are used as the nitrating agent: Into an iron water-jacketed vessel provided with a stirrer is introduced one part by weight of 2.4-dinitrodiphenylamine at a temperature of about 70 deg. C., together with five parts by weight of mixed acid containing approximately 30 per cent nitric acid, 55 per cent sulphuric acid, and 15 per cent water. Thereafter the temperature is raised to from 80 to 90 deg. C., in any suitable manner, and the agitation is continued at this temperature for approximately one hour. Thereupon the mixture is cooled to 30 deg. C., and the solid 2.4.2'.4'-tetranitrodiphenylamine is separated from the spent acid by filtration. The material thus obtained, in an acid condition, is added, at 70 deg. C., to five parts by weight of mixed acids containing 20 per cent nitric acid, 75 to 80 per cent sulphuric acid and 5 to 0 per cent water in the vessel previously referred to. The mixture is then raised to 80 to 90 deg. C., and kept at this temperature for from 1 to 2 hr. The solid 2.4.6.2'.4'.6'-hexanitrodiphenylamine is separated from the spent acid by filtration, is drowned in water, and washed with hot water until freed from acid. Afterward it is centrifuged from the wash water and dried. (1,326,947; assigned to E. I. du Pont de Nemours & Co.; Jan. 6, 1920.)

Recovery of Molybdenum From Its Ores.—HENRY ALFRED DOERNER of Meriden, Conn., has developed a process whereby molybdenum may be recovered from its ores by heating to about 500 deg. C. in a stream of chlorine gas. The molybdenum is volatilized as chlorides or oxychlorides, and these may be condensed, or may be decomposed by steam or water into oxides and hydrochloric acid. By maintaining the condenser at a temperature of 200 deg. C., the hydrochloric acid may be separated from the oxides and recovered in a separate condenser. (1,329,380; Feb. 3, 1920.)

Purification of Zinc Solution. — The successful deposition of zinc by electrolysis from the sulphate solution obtained by leaching roasted zinc-bearing material with solutions containing sulphuric acid is dependent upon the production of a solution of a high order of purity and entails the elimination of such impurities as copper, cadmium, iron, arsenic, antimony, nickel and cobalt. SAMUEL FIELD of London, England, proposes to lixiviate roasted zinc ores in the presence of ozone for the purpose of preventing the formation of iron salts. This is carried on in the presence of a catalyst, for example a manganese compound, and in a warm solution (80 to 100 deg. C.). Materials suitable for treating the solution in conjunction with ozone are manganese dioxide and hydrate; lead oxide and carbonate; zinc oxide, hydrate and carbonate. The result of this treatment is that any iron present is completely precipitated as ferric hydroxide, cobalt is thrown down as a higher insoluble oxide, and with these metals any arsenic and antimony present are also thrown down. Copper, nickel and cadmium are not, however, completely removed, but traces of these metals remaining may be removed by treatment with zinc fume. (1,331,334; Feb. 17, 1920.)

Process for Producing Refractory Compounds.—As is well known, domestic magnesite does not produce a satisfactory refractory, either in the grain form or when made into brick, without the addition of a bonding material. The process of producing a refractory, similar to Austrian magnesite, which consists in pulverizing and mixing calcined magnesite with a definite amount of an iron compound (sulphate, etc.) and silica to produce a material of approximately the following composition: magnesia, 86 per cent; iron oxide, 8 per cent, and silica, 6 per cent, after the mixture has been burned at a temperature of between 1,540 and 1,750 deg. C. has been patented by WILFRED M. HANDY of Spokane, Wash. (1,330,268; Feb. 10, 1920.)

Continuous Production of Ether.—Two forms of apparatus for the continuous production of ether are described by EMILE A. BARBET of Paris, France. The accompanying figure represents one type and will serve to demonstrate the principle, which is the same in each case. Alcohol is heated in *A*, the vapors passing through *B* to the bottom of the tower *C*, which is filled with acid-proof packing material. Sulphuric acid regenerated in the second step of the process also enters



APPARATUS FOR CONTINUOUS PRODUCTION OF ETHER

the bottom of tower *C* through *D*. The alcohol vapor and sulphuric acid pass concurrently upward through tower *C*, reacting to form ethyl sulphuric acid, which overflows through *C* into the still *D*. This still is heated by the steam coil *E* and the ethyl sulphuric acid is decomposed with the production of ether and the regeneration of the sulphuric acid which passes out through *D*, thus completing the cycle. (1,328,258; assigned to E. Barbet & Fils & Cie., of Paris, France; Jan. 20, 1920.)

Synthetic Production of Cyanides and Nitrides.—Instead of forcing air through a heated mixture of carbon and alkali, AXEL R. LINDBLAD of Stockholm, Sweden, uses an electric furnace in which the air or nitrogen is sucked through the mass, thereby avoiding the necessity of heating to the reaction temperature large volumes of air which, in the former method, escape through the walls of the furnace. The cyanide volatilizes as formed and is drawn off with the exit gases. In the production of nitrides, the finished product is raked out through a discharge opening in the lower part of the furnace. (1,328,575; Jan. 20, 1920.)

Personal

M. LOUIS BOYER, representative of the firm of Gaillard, of Bezieres, France, recently visited the Burgess Laboratories, Madison, Wis.

J. A. BRETZ, chief chemist for the Bettendorf Co., Bettendorf, Pa., and president of the Chemists' Club of the Tri-Cities, is now chief chemist for the Southern Manganese Corporation at Anniston, Ala.

BRUCE K. BROWN has joined the staff of the Burgess Laboratories, Madison, Wis.

J. M. CLARK, formerly chief chemist for the Sherwin-Williams Chicago plant, is now superintendent for the Delora Smelting & Refining Co. at Delora, Ont., Canada.

LEVERETT DAVIS, consulting engineer, of Denver, Col., has been in New York on professional business.

W. M. DREW has been made manager of the Cleveland branch of Marden, Orth & Hastings Corporation, succeeding H. W. Galley.

Dr. FEDERICO GIOLITTI has sailed for Italy after a stay of several months in the United States, in the interests of his clients, G. Ansaldo Co., Stein & Co., and the Fiat Automobile Co.
